THE soil is constantly giving off ammonia and at the same time absorbing it from the air, which contains, in Paris, about 1 mgrm. in 50,000 litres. It is possible, by altering the composition of the air on the one hand, and the condition of the soil as to amount of surface exposed, the amount of moisture, and the amount of decomposition going on in it, on the other hand, to ensure the nearly complete absorption of the atmospheric ammonia by the soil or the evolution of much of the nitrogen, already in the soil, as ammonia. Thus, conclusions drawn from experiments are only applicable to cases where the conditions are exactly the same, cases which may by accident recur, but can hardly be relied upon as doing so.

The uniform correction which Schloesing makes for ammonia absorbed in his experiments is thus inaccurate; moreover, it is obtained by regarding a surface of dilute sulphuric acid as having the same power of absorbing ammonia as an equal surface of soil which may be absorbing ammonia at one point and giving it up at another. The same *savant* maintains that the absorption of nitrogen in his experiments is due only to absorption of atmospheric ammonia, but he does not prove it directly by determining the amount of ammonia lost by the air passed over the soil.

Fixation of ammonia from the air, if occurring at all must be very small; most *savants* are agreed as to this, and also allow that the atmospheric ammonia must be chiefly derived from the decay of nitrogenous organic matter derived from vegetation.—A. G. B.

*Distribution of Aluminium in Plants.* L. Ricciardi. *Gazetta Chem. Ital.* **19**, 150—159.

ALUMINA is found in the ash of all Italian plants. It is in the most assimilable form in moderately calcareous soils, and less so in clay, highly calcareous soils, and soils from igneous rocks. The ash of vines grown on—

	Per Cent. of Alumina.
Clay soil contained .....	0.850
On highly calcareous soil contained.....	0.810
On medium calcareous soil contained.....	1.140

The alumina is most abundant in the stems and stalks, less so in the seeds and skins, and least in the leaves. The following are a few results obtained:—

	Alumina, per Cent. in the Ash.
Mandarin orange—stem and stalk.....	0.218
Mandarin orange—peel and seed.....	0.093
Mandarin orange—leaves.....	0.022
Figs, Bari.....	0.063
Figs, Catania.....	0.092
Dry almonds—shell.....	0.185
Dry almonds—nut.....	0.138
Ceratonia siliqua, Bari—pulp.....	0.502
Ceratonia siliqua, Bari—seed.....	0.062
Ceratonia siliqua, Catania—pulp.....	0.607
Ceratonia siliqua, Catania—seed.....	0.064
Tobacco leaf.....	2.151
White lupin.....	0.012
Apulian wine, grms. per litre.....	0.022

Besides alumina, manganese was always detected.

—D. A. L.

*Examination of Vines after Treatment with Copper Salts.*  
E. Comboni. *Rassegna di Viticoltura ed enologia*, 1889,  
225—229.

THE author has made various determinations from which the following conclusions are drawn. The quantity of copper retained by the grapes depends on the care taken in the application of the copper salt to the vine, whether the leaves only are covered or not. More copper may be expected in the wine when the copper salt is mixed with lime than when simple copper sulphate solution is used. Grape skins and pulp have a noteworthy amount of copper; the stalks and stones also contain it, the latter in very small quantity, frequently only a trace. Thick wine contains more than clear. Further experiments are required to ascertain if the presence of copper inside the grape has anything to do with the developing processes.—D. A. L.

#### *The Saxmundham Experimental Farm.*

THE East Suffolk Chamber of Agriculture has issued a report of some experiments carried out during the last eight years by Mr. Edward Packard, jun., on his experimental farm at Saxmundham, Suffolk. The soil is poor, and the crops accordingly were not at all heavy where wheat was grown continuously, except in one year out of the eight, when the land was foul and the crop was missed. What is called a complete manure, composed of 33 lb. of lime per acre, 22½ lb. of magnesia, 75 lb. of potash, 47 lb. of phosphoric acid, and 40 lb. of nitrogen (equal to 2 cwt. of sulphate of ammonia), was used on one plot, while another plot had no manure, and from each of the rest one of the ingredients of the complete manure was omitted. The average produce of the seven years' cropping is given below:—

Manures.	Produce per Acre.	
	Bush.	Pecks.
None.....	21	1½
Complete manure.....	30	2
Lime omitted.....	28	3½
Potash omitted.....	29	0½
Nitrogen omitted.....	26	1½
Phosphoric acid omitted.....	26	0½
Magnesia omitted.....	30	1½

There was an increase of about nine bushels an acre from the use of the complete manure; but this was scarcely enough to pay expenses. The omission of the lime from the complete manure reduced the yield by nearly two bushels an acre, and there was a greater reduction when

nitrogen or phosphoric acid was left out; but the benefit of the magnesia was practically nothing, and that of the potash was only a bushel an acre. It is strange that on poor land the omission of the nitrogen did not make more difference in the yield than is shown by the figures. In similar experiments with barley, the average results of seven years show a yield of about 24½ bushels on the unmanured plot, 41 from the complete manure, 36¾ when phosphoric acid was omitted, 34¼ when nitrogen was left out, nearly 38½ without potash, 37¾ without lime, and 37 when magnesia was omitted. All the ingredients, then, were necessary to the production of a full crop of barley. On other barley plots, 4 cwt. of superphosphate and 2 cwt. of kainit per acre were used in each case, and nitrogenous manures in different forms were added to different plots, each dressing containing 53 lb. per acre of nitrogen. Muriate of ammonia gave the greatest yield, or 38 bushels an acre, nitrate of soda coming next with only a quarter of a peck less, and then sulphate of ammonia, with 4½ pecks less. The crops were grown continuously on the same land. For mangolds, the complete manure was made up of the following ingredients, the quantities of the more important substances being those removed by an average crop, excepting that the quantity of nitrogen was only half as much as is removed:—96 lb. of nitrogen, 322 lb. of potash, 51 lb. of phosphoric acid, 36 lb. of lime, 81 lb. of soda, 36 lb. of magnesia, 122½ lb. of sulphuric acid, and 92 lb. of chlorine. The average produce of seven years on the unmanured plot was 24,054 lb. an acre, and that of the plot to which the complete manure was applied was 48,935 lb. When nitrogen alone was left out the yield was only 36,754 lb., and when phosphoric acid was omitted it was no more than 39,570 lb.; but the omission of any of the other ingredients made much less difference, though where magnesia was withheld the yield was 3,422 lb. less than where the complete manure was used, and the absence of lime or potash caused a decrease of about 1,500 lb. Dissolved phosphate (or superphosphate) proved greatly superior to ground coprolite.

#### PATENTS.

*Improved Method of and Means for Preserving Grass, Cereals, Herbage, or other Vegetable Substances, as Eusilage or Food for Cattle and other Animals.* J. Pearson, Wolverhampton. Eng. Pat. 4363, March 13, 1889. 6d.

This invention relates to the application of an exhaust fan worked by hand or other power to silos, and also to providing them with drains, for the emission of liquids, which can be closed air-tight.

The silo, or receptacle, filled with grass or cereals, &c., so as to leave a vacant space at the top, is made air-tight or nearly so; the exhaust fan and pipe are then attached, the latter either penetrating into the mass or preferably only entering the vacant space, and by working the fan the volume of internal air is reduced to effect the preservation of the contents.—D. A. L.

*Improved Manurial Composition or Stimulant for Plants, Bulbs, Trees, and other Vegetable Produce.* A. Booty, High Harrogate. Eng. Pat. 8782, May 27, 1889. 4d.

This invention relates to a manurial composition containing the following ingredients in about the quantities given:—1 ton prepared fuller's earth; 1 ton of clay; 2½ cwt. of calcium sulphate; 2½ cwt. of neutral calcium phosphate; 2½ cwt. of ammonium sulphate; 1½ cwt. of potassium nitrate; ¾ cwt. of fused potassium chloride; ¼ cwt. of ferrous sulphate and a small quantity of gelatin. The proportions may, however, be varied to suit the plant. They are pulverised and mixed dry.—D. A. L.

## XVI.—SUGAR, STARCH, GUM, Etc.

*The General Meeting of the Society of Distillers; and the Society of Starch Manufacturers, in Germany.* February 28 and March 1890. Chem. Zeit. 14, 305–306.

1. *Meeting of Starch Manufacturers.*—Saare discussed the question of the grinding of potatoes, and expressed his opinion that a more complete subdivision than is at present possible by mechanical means is not to be expected. It remains to be seen whether a bacterial and a slightly acid fermentation will more effectually separate the starch cells. By the use of grinding-mills to still further subdivide the pulp from the graters, a larger yield of starch is undoubtedly obtained, but the sieves are easily blocked by the extremely fine pulp thus produced. Of the more modern forms of apparatus the compound and excelsior graters are the most efficient. As regards the feasibility of adding starch to rye and wheat flour to be used in bread making, Delbrück recommends the addition of 10–20 per cent. of starch; and states that there is no difficulty in incorporating the previously gelatinised starch with the flour. Zuntz reports concerning its nutritive value, and shows that bread baked with the addition of skim-milk and 20 per cent. of starch does not contain appreciably less albuminoid matter than bread baked without the addition of starch.

2. *Meeting of Distillers.* See under XVII., page 529.

—H. T. P.

*On the Presence of Sugar-yielding insoluble Carbohydrates in Seeds.* W. Maxwell. Amer. Chem. J. 12, 51–60.

In the chemical analysis of seeds and plants there has generally been admitted a large percentage residue of "undetermined matter." These undetermined matters, excluding nitrogenous substances whose nature is not fully understood, have been summarily expressed as nitrogen-free extract matter (N-freie Extractstoffe). The author has investigated the legumes, *Pisum sativum*, *Faba vulgaris*, and *Vicia sativa*, with especial regard to the non-nitrogenous insoluble residues. As a result of these experiments it appears that the insoluble non-nitrogenous bodies of legumes are, exclusive of cellulose, chiefly carbohydrate bodies more or less convertible by dilute mineral acid into sugars. The sugar most constantly yielded by hydration of these carbohydrates is galactose, indicating that the carbohydrate is paragalactin. About one-fifth of the total matter of the seed, *Pisum sativum*, consists of a carbohydrate wholly convertible into galactose. The seeds of *Faba vulgaris* and *Vicia sativa* contain respectively 14 and 15 per cent. of the non-nitrogenous bodies, but only about one-half of the substance in this case yields sugar with mineral acids. Kramer has determined microscopically that the bodies are secreted in the cells of the endosperm, and must be regarded as a reserve material of the seed and as contributing to the support of the embryo during germination. Chemically these carbohydrates are distinguished from the soluble carbohydrates by their insolubility in water and diastase.—A. J. K.

*Organic Acids in the Juices of the Sorghum Cane.* H. W. Wiley and W. Maxwell. Amer. Chem. J. 12, 216.

PRELIMINARY investigation has revealed in the juices of the sorghum cane the following acids which have been obtained as free crystallised bodies or as salts. The experiments also indicate that the acids are present in the following order by proportion:—Aconitic, citric, malic, oleic, formic, tartaric, and traces of acetic and oxalic. The researches will be continued next season.—A. J. K.

*Note on Xylose and Gum from Straw and other Materials.*  
Allen and Tollens. Ber. 23, 137.

SEEING that many vegetable products give furfural when boiled with acids and a red colouration on warming with phloroglucinol and hydrochloric acid, which reactions are characteristic of the pentaglucooses, arabinose and xylose, the authors deemed it of interest to determine if either of these sugars could be isolated from those substances.

They have examined beechwood, wheat, straw, loofah, cherry-tree wood. On extracting loofah, cherry-tree wood, and straw with soda lye, and precipitating the extract with alcohol, a gum was obtained (15 per cent. from straw), which gave xylose on hydrolysis. The production of furfural is more regular when the substances are distilled with hydrochloric acid instead of sulphuric acid. The authors hope soon to be able to communicate further on these matters.—A. L. S.

*Syntheses of Mannose and Levulose.* E. Fischer. Ber. 23, 370—394.

THE lactone of mannonic acid is so similar in its properties to that of arabinose-carboxylic acid, that it would be impossible to distinguish between them if it were not that the first is dextro-rotatory and the second levo-rotatory, the numbers expressing the rotation being almost the same in the two cases. On mixing solutions of these they unite to form an optically inactive lactone, which yields inactive salts, and this cannot be easily again separated into its two constituents.

All three lactones yield by reduction first a sugar and then a hexahydric alcohol, these reduction products standing in exactly the same relation to one another as the lactones.

As it is advisable to have a systematic notation for these and similar bodies, the author recommends that the letters *l*, *i*, or *d* be prefixed respectively to the names of the bodies according as the sugars from which they are derived are levo-rotatory, inactive, or dextro-rotatory. The following table shows the relation of these bodies to one another:—

<i>d</i> -Mannose (ordinary mannose levo-rotatory).	<i>i</i> -Mannose.	<i>l</i> -Mannose (levo-rotatory).
<i>d</i> -Mannose-phenyl- hydrazone (levo-rotatory).	<i>i</i> -Mannose-phenyl- hydrazone.	<i>l</i> -Mannose-phenyl- hydrazone (dextro-rotatory).
<i>d</i> -Mannonic acid.	<i>i</i> -Mannonic acid.	Arabinose-carboxylic acid ( <i>l</i> -Mannonic acid).
<i>d</i> -Mannonic acid lactone (dextro-rotatory).	<i>i</i> -Mannonic acid lactone.	Arabinose-carboxylic acid lactone (levo-rotatory).
<i>d</i> -Mannitol (dextro-rotatory in presence of borax).	<i>i</i> Mannitol.	<i>l</i> -Mannitol (levo-rotatory in presence of borax).
<i>d</i> -Phenylglucosazone (ordinary glucos- azone) (levo-rotatory in acetic acid solution).	<i>i</i> -Phenylglucosazone	<i>l</i> -Phenylglucosazone (levo-rotatory in acetic acid solution).

*l*-Mannose is obtained by reducing arabinose-carboxylic acid with sodium amalgam. The solution is cooled before the addition of sodium amalgam, and sulphuric acid is added from time to time in sufficient quantity to keep the solution acid. The reduction is complete in about three-quarters of an hour, the neutralised solution is evaporated, and the sodium sulphate allowed to crystallise out. The mother-liquor is mixed with 20 times its volume of alcohol, and the alcoholic filtrate from this on evaporation gives a colourless syrup of *l*-mannose. The yield of sugar is 50 per cent. of the theoretical. It is easily soluble in water, with difficulty in alcohol, and fairly easily in methyl alcohol. It is levo-rotatory, although the exact amount could not be determined as the body was not obtained in a pure state. Its hydrazone is dextro-rotatory, and melts at 195°, with evolution of gas.

*l*-Phenylglucosazone is formed by heating the above hydrazone with twice its weight of phenylhydrazine acetate. It is very similar to *d*-phenylglucosazone (from *d*-mannose, levulose, and dextrose); it melts at 205° with evolution of gas. It is dextro-rotatory. Concentrated hydrochloric acid decomposes it into phenylhydrazine hydrochloride and its osone, and this latter gives by reduction with zinc and acetic acid, *d*-levulose, the formation of which from *l*-levulose is given further on. *l*-Mannose is with great difficulty, if at all, fermentable with beer yeast.

*l*-Mannitol is formed by the reduction of *l* mannose with sodium amalgam, but this reaction takes place much more slowly than the reduction of the lactone to *l*-mannose. The reduction is finished in about 12 hours. The solution is then neutralised, evaporated until sodium sulphate commences to crystallise out, mixed with 20 times its volume of alcohol, filtered, and evaporated, when *l*-mannitol remains as a white crystalline mass; it is purified by recrystallisation from methyl alcohol. It is very similar to ordinary mannitol melting 2° lower (163°—164°), easily soluble in water, with difficulty in alcohol, and much more easily in methyl alcohol. It has a sweet taste, and does not reduce Fehling's solution. In the presence of borax it is strongly levo-rotatory.

*i*-Mannonic Acid.—If equal parts of mannonic acid lactone and arabinose-carboxylic acid lactone be dissolved in water, the solution is optically inactive, and on evaporation yields a colourless radiating mass of crystals of the lactone of *i*-mannonic acid. This is easily soluble in hot water, and on cooling deposits radiating masses of long prisms; it is with difficulty soluble in hot alcohol, and on cooling is similarly deposited in radiating masses of long needles. It melts at a slightly higher temperature than its components, has a sweet taste, and does not reduce Fehling's solution. It is optically inactive, even in strong solutions, and cannot be separated into its components by crystallisation. It forms optically inactive salts, which may be distinguished from those of arabinose-carboxylic acid and of mannonic acid by the difference in their solubilities, &c. It also forms basic salts, which is not the case with its two component acids; but in which behaviour it resembles gluconic acid. Heated with phenylhydrazine acetate it yields a hydrazone.

The author has applied the two methods which Pasteur employed to resolve inactive tartaric acid into its components, so as to obtain *i*-mannonic acid.

By fermentation with *Penicillium glaucum*, little if any separation was effected. By means of the strychnine salts a complete decomposition into dextro- and levo-rotatory acids was effected. The base and lactone are dissolved in molecular proportions by boiling in 70 per cent. alcohol; the salt is obtained on evaporation; it is rubbed down and washed with alcohol. It is soluble in hot water; small quantities added to hot alcohol dissolve at first to a clear solution, but in a very short time a crystallisation of the difficultly soluble arabinose-carboxylic acid begins, the greater portion of this crystallises out, leaving the more easily soluble salt of *d*-mannonic acid in solution. These two salts may then be purified by recrystallisation, &c.

*i*-Mannose is prepared from *i*-mannonic acid lactone in the same way as *l*-mannose is, from the *l*-acid. It is a colourless syrup, easily soluble in water, with difficulty in alcohol, and fairly easily in hot methyl alcohol. Except that it is optically inactive, it exactly resembles *d*- and *l* mannose. It yields a hydrazone in the usual way, which melts with decomposition at 195°.

As *l*-mannose is unfermentable and *d*-mannose easily fermentable by beer yeast, it might be expected that *i*-mannose would undergo a partial fermentation under the influence of beer yeast. This is found to be the case, and the unfermentable residue is found to be *l*-mannose.

*i*-Phenylglucosazone is formed by heating *i*-mannose with twice its weight of phenylhydrazine and sufficiently dilute acetic acid. The reaction takes some hours, and the yield is rather smaller than usual. It melts at 217°—218° with decomposition, and in acetic acid solution is optically inactive. This body is identical with  $\alpha$ -erosazone, and the author proposes in future to call it by this name.

*i*-Mannitol ( $\alpha$ -acritol) is formed by the reduction of *i*-mannose, just as *l*-mannitol is obtained from *l*-mannose. The yield is 40 per cent. on the weight of sugar. It is purified by recrystallisation from methyl alcohol. It melts at 170°. It is very soluble in warm water and crystallises out on cooling in small prisms; it is fairly easily soluble in hot glacial acetic acid, and with great difficulty in ethyl and methyl alcohol. It is optically inactive and is identical with  $\alpha$ -acritol. The author points out that in identifying any particular hydrazone or osazone it is not sufficient to show that it agrees in melting point, solubility, &c., with some known hydrazone or osazone, as this would lead one to conclude that the derivatives from *d*-, *i*-, and *l*-mannose were identical; but also that it is necessary to show that their action on polarised light is the same, this being the only satisfactory way of differentiating such bodies as derivatives of these three sugars.

**Constitution of  $\alpha$ -Acrose.**—A sugar has been prepared from acrolein bromide, glycerose (a mixture of glycerol and dioxacetone), and formaldehyde. It can only be isolated as  $\alpha$ -acrosazone; this may be converted into the osone by the action of hydrochloric acid, and the latter yields by reduction with zinc and acetic acid a sugar ( $\alpha$ -acrose) which may or may not be identical with the original one. It yields by further reduction  $\alpha$ -acritol, which is identical with *i*-mannitol;  $\alpha$ -acrosazone is identical with *i*-phenylglucosazone.

The constitution of  $\alpha$ -acrose may be either—

as both would yield the same osazone and the same hexahydric alcohol. The first is the formula of mannose, the second of levulose. *i*-Mannose yields a very characteristic difficultly soluble hydrazone, whereas  $\alpha$ -acrose does not, so that  $\alpha$ -acrose is *i*-levulose, and its constitution is expressed by the second formula. It may be that the originally obtained sugar is not identical with that obtained by reduction of the osone; a solution containing this sugar was prepared from acrolein bromide and formaldehyde. In both cases the reaction with phenylhydrazine did not correspond to that of *i*-mannose, and so in both cases the sugars were *i*-levulose.

**Fermentation of *i*-Levulose ( $\alpha$ -Acrose).**—The synthetically obtained sugar ferments easily with beer-yeast, and after fermentation has a strong dextro-rotation, which is evidently due to *l*-levulose;\* as the solution yields an osazone, which is identical with *i*-phenylglucosazone.

**Conversion of *i*-Mannitol into *i*-Mannonic acid.**—Nitric acid oxidises *i*-mannitol to *i*-mannose just as ordinary mannitol is oxidised to mannose. The *i*-mannose is obtained from the neutralised solution as phenylhydrazone. *i*-Mannitol prepared in one case from *i*-mannonic acid, and in another synthetically from glycerol gave, in both cases, the same sugar as phenylhydrazone; which was identical with *i*-mannose phenylhydrazone; and when decomposed with hydrochloric acid gave *i*-mannose.

Bromine water oxidises the sugar to mannonic acid, which is obtained by heating with phenylhydrazine acetate as a hydrazone. This yields the free acid when decomposed by baryta water, and the baryta removed by sulphuric acid.

The *i*-mannonic acid is then decomposed as described above into *d*-mannonic acid and arabinose-carboxylic acid. The synthesis of all the bodies of the mannose group, except dextrose, has now been made, and may be briefly summarised as follows:—

The sugar,  $\alpha$ -acrose, synthetically obtained from acrolein bromide, glycerose or formaldehyde yields by heating with phenylhydrazine and acetic acid *i*-phenylglucosazone, which with hydrochloric acid yields *i*-glucosone, by reduction with zinc and acetic acid this yields *i*-levulose and with beer yeast it partially ferments, thus leaving *l*-levulose. Returning to *i*-levulose, by reduction with sodium amalgam *i*-mannitol ( $\alpha$ -acritol) is obtained, this oxidised with nitric acid yields *i*-mannose and this oxidised with bromine water yields *i*-mannonic acid; the strychnine or morphine salts of this

may be decomposed into the salts of *l*-mannonic and *d*-mannonic acid; *l*-mannonic acid (arabinose-carboxylic acid) may be reduced first to *l*-mannose and then to *l*-mannitol; *d*-mannonic acid may be reduced to *d*-mannose and *d*-mannitol (ordinary mannitol); *d*-mannose may be converted into *d*-phenylglucosazone by phenylhydrazine acetate, this is decomposed by hydrochloric acid yielding *d*-glucosone and then by reduction yields *d*-levulose (ordinary levulose); or the *d*-phenylglucosazone may be reduced to *iso*-glucosamine which decomposed by hydrochloric acid yields *d*-levulose.

*d*-Mannonic acid and gluconic acid are closely related, the author hopes soon to be able to synthesise the latter, and consequently also dextrose. In the coming year the author proposes to determine if, besides dextrose and other sugars of the *d*-mannitol group, there are also formed by plants derivatives of the *l*- and *i*-mannitol group. He thinks that this is probable, as arabinose belongs to the *l*-mannitol group; and that possibly the formation of the carbohydrates in plants may take place on somewhat similar lines to those of the above syntheses.—A. L. S.

#### On the Preparation of Levulose-carboxylic Acid.

H. Kiliani and G. Düll. Ber. 23, 449—451.

HAVING had to prepare levulose carboxylic acid in quantity, in order to investigate the action of oxidising agents on it, the authors not being satisfied with the previously described methods (Ber. 18, 3070; 19, 221 and 1914), have devised one more satisfactory in every way.

They do not recommend Fischer and Passmore's method (Ber. 22, 2728), in which use is made of the phenylhydrazide of the acid, but recommend the preparation of the pure cyanhydrin and the decomposition of this by hydrochloric acid, particular attention being paid to the two items that: (1) the levulose syrup be prepared according to König (Monatsh. 1883, 562), and so that it contains 25—30 per cent. of water, and that (2) the chief portion of the hydrochloric acid be expelled by evaporation.

The authors give very full directions as to the carrying out of the experiments.

The pure lactone of levulose-carboxylic acid gives with aqueous ammonia a fine crystalline derivative, not yet fully investigated. On oxidation with nitric acid a polybasic acid is formed, which may be isolated as a crystalline calcium salt which will be further investigated by the authors.—A. L. S.

#### Synthesis of Grape Sugar. E. Fischer. Ber. 23, 799—805.

THE author converts *d*-mannonic acid into gluconic acid by heating 20 parts of the former with 40 parts of quinoline and five parts of water for 20 minutes at 150° C., and then for 40 minutes longer at 140° C. A solution of 40 parts of crystallised barium hydrate is added, and the quinoline removed by distillation with steam. To separate from the *d*-mannonic acid the barium is precipitated with the exact amount of sulphuric acid; the filtrate from barium sulphate is evaporated to about 150 cc., and then boiled for half-an-hour with 60 grms. of brucine, which will be entirely dissolved. After standing for some time at ordinary temperature the excess of brucine separates out in crystals. The filtrate is evaporated until barium mamonate begins to crystallise, and then poured into 25 times its volume of absolute alcohol, in which barium mamonate is nearly insoluble. It begins at once to separate out. After filtration the alcoholic filtrate is again evaporated, the resulting syrup dissolved in water and decomposed with 20 grms. of crystallised barium hydrate, when the brucine is partly precipitated and separated in crystals. To remove that part of the base which remained dissolved the aqueous solution is again evaporated to a syrup and then treated with hot alcohol. The brucine is dissolved, whilst the residue contains the barium compounds. This is redissolved in hot water, the barium carefully precipitated by sulphuric acid, and the filtrate from the barium sulphate, containing gluconic acid, treated with animal charcoal. For further

\* The author suggests that if the name *l*-levulose be objected to that it might be called anti-levulose, and that the old name levulose might then be retained for the *d*-sugar.

purification the phenylhydrazide was prepared by heating the liquid, after concentration to 30 cc., with three parts of phenylhydrazine and the corresponding quantity of acetic acid. It melts at 206° C. The calcium, barium, and cinchonine salt of the synthetic gluconic acid were prepared from the hydrazide and proved to be identical with the salts obtained from the ordinary gluconic acid.

**Conversion of Gluconic Acid into Glucose.**—A solution of gluconic acid prepared from the pure calcium salt by precipitation with oxalic acid, is concentrated on the water bath to a syrup to convert the greatest possible amount of the acid into its lactone. It is then redissolved in 9 parts of water, the mixture cooled to 0° C., and a small quantity of sulphuric acid added to it. Sodium amalgam is added in small portions, and is very quickly consumed. It is necessary to add from time to time small quantities of sulphuric acid to keep the mixture acid. About 8 parts of the amalgam are required to 1 of the syrup. To isolate the sugar the solution is neutralised, evaporated until sodium sulphate begins to crystallise out, and poured into an abundant quantity of hot alcohol. Sodium sulphate is precipitated. The alcohol contains, besides glucose, sodium salts of organic acids. On repeating this method of purification several times, pure glucose crystallises from the alcohol after several additions of small quantities of ether. It has all the properties of ordinary glucose.—A. L.

**On a New Inosite called Racemo-Inosite.** Maquenne and C. Tanret. *Compt. Rend.* **110**, 86-88.

The authors discovered independently that the action of hydriodic acid on pinite yields methyl iodide and a dextro-rotatory inosite, the same reaction with quebrachite yielding methyl iodide and a levo-rotatory inosite. (See this Journal, 1890, 202 and 311.) They seek to show in this joint paper that these two inosites are in every way comparable to the dextro- and levo-rotatory tartaric acids.

(1.) They have equal and opposite rotatory powers  $[\alpha_D] = +65^\circ$  for the anhydrous sugars;  $[\alpha_D] = \pm 55^\circ$  in the hydrated state. The rotatory power is the same in 5 per cent. and 10 per cent. solutions, and whether the inosites be dissolved in hot or cold water.

(2.) The rotatory power of the acetic ethers were found to be  $[\alpha_D] = +9.75^\circ$  and  $[\alpha_D] = -10^\circ$ . They are both amorphous and soften when heated by the hand; and they both fuse without decomposition at 247°.

(3.) The two benzoic ethers fuse at 252°, and are but slightly soluble. They both crystallise with 2 H<sub>2</sub>O. The dextro-rotatory inosite has also been obtained anhydrous.

(4.) The two inosites crystallising with 2 H<sub>2</sub>O have about the same solubility; the dextro-rotatory compound dissolves in 2.13 parts of water at 14° and the levo in 2.3 parts at 14°. The anhydrous bodies both dissolve in 1.5 water at 11°.

(5.) They both behave in the same way towards reagents, and both crystallise in hemihedral rhomboidal prisms.

The authors have obtained the inactive inosite (corresponding to racemic acid) *racemo-inosite* by mixing 25 per cent. solutions of these two inosites; from this mixture *racemo-inosite* crystallises out in a short time. Its physical properties are quite different from those of its constituents and from those of ordinary inosite. It is optically inactive; it melts at 233° (30° higher than ordinary inosite) without previous softening. It is soluble in 26 parts of water at 11°, in 22 at 15°. The acetic ether crystallises; its melting point being 111°. The benzoic ether crystallises in cottony crystals, melting point 217°. Unlike ordinary inosite it does not turn Fehling's solution green when heated. Its composition is absolutely identical with that of the other inosites.

Since this inosite is the compound inactive by compensation, it seems certain that the ordinary inosite of muscular tissue, baricot beans, walnut leaves, &c., is the compound inactive by constitution. The authors propose to prove this experimentally. They note that their researches offer the first instance of optical isomerism in the sugars.

## PATENT.

*Improvements relating to Apparatus for the Manufacture of Sugar.* G. Adant, Brussels, Belgium. Eng. Pat. 7517, May 4, 1889. 8d.

This invention relates to apparatus for the manufacture of sugar in blocks, slabs, or bars, and is designed to improve the apparatus described by Eng. Pat. 13,084 of 1888 (this Journal, 1889, 810).—A. J. K.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*The General Meeting of the Society of Distillers and the Society of Starch Manufacturers in Germany.* Berlin, February 28 and March 1, 1890. *Chem. Zeit.* **14**, 305-306.

1. *Meeting of Starch Manufacturers.*—See under XVI., page 526.

2. *Meeting of Distillers.*—According to Delbrück, the addition of hydrofluoric acid to worts greatly checks the growth of false ferments. Fermentation is somewhat checked, but the yield of alcohol is undiminished, and appears to be of a better quality. Lintner describes some experiments which he made in conjunction with Irmisch and Gronow to determine the species of yeast most suitable for the fermentation of strong distillers' worts. Thirty-seven pure cultures of (a) brewer's bottom-yeast; (b) brewer's top-yeast; (c) disease-forms of brewer's yeast; (d) white-beer yeast; (e), distiller's yeast; (f) pressed yeast, were placed, partly in wort, partly in 30 per cent. solutions of maltose. The results obtained varied greatly so far as the yield of alcohol, yeast-crop, amount of sediment, and of skimmings are concerned. Some varieties of white-beer yeast yielded very large yeast-crops, and would therefore be suitable for pressed-yeast manufactories. A sample of white-beer yeast also produced the largest amount of alcohol (16 per cent. of alcohol by volume). Delbrück discussed the effect of aeration on yeast and fermentation, and its utilisation in pressed yeast manufactories and in the fermentation of strong worts. Although aeration may cause a loss of alcohol up to 8 per cent. of the whole, yet by this means some species of yeast may be made to go on working till 16 per cent. of alcohol is formed. Delbrück recommends the employment of aeration combined with stirring apparatus for strong distillers' worts. The yeast used should be a pure culture, and the time of fermentation should be curtailed as much as possible. At the beginning, however, after the first aeration, it is well to somewhat check the rapidity of fermentation.—H. T. P.

*Production of Cider in France.* Soc. Arts J. **38**, 538-540.

This article is an abstract of the report of the United States Consul General at Paris. The quality of apples grown on various soils and the nature of the cider produced from them is first considered. The best soil is a mixture of clay and sand with plenty of moisture. It has been decided that to make the best cider the apples should have the following composition:—Water, 80 per cent.; sugar, 17.3 per cent.; tannin, 0.5 per cent.; mucilage, 1.2 per cent.; "fermenting acid," 0.167 per cent.; other substances, 0.833 per cent. Only very few varieties contain the above constituents in the desired proportions; and it is therefore usual to mix different kinds, only those of the same season being used. A list is given of varieties containing the principal constituents in the right proportions; and also of species rich in tannin and sugar respectively. There are three methods in use for reducing the apples to pulp. First, by a machine consisting of a circular trough, around which a stone wheel is made to revolve by horse-power. This machine is being superseded by two new kinds of apparatus. These are the grater—a machine with small saw-like teeth set close

together, and the crusher, a kind of magnified coffee mill, capable of producing 60—80 hectolitres (hectolitre = 2.75 bushels) of pulp per hour. This is the best machine, as it does not crush the pips, the essential oil of which imparts a disagreeable flavour to the cider. The pulp is allowed to macerate in vats for 12—15 hours. Before putting it into the press, the bottom of the latter is lined with a thin layer of straw, a wire netting, or small oak, or beech branches. Straw is objectionable, as it imparts a bitter taste to the juice, while the above named woods yield a little additional tannin, so necessary to preserve the cider. By the hydraulic presses now in use are obtained 65—75 per cent. of the pure juice at first pressure, without drainage. Diffusion processes have been tried in cider making. The older methods were only used in those cases where presses were not obtainable. Recently, however, new diffusion methods have been discovered by means of which the inventors claim to be able to get 85—95 per cent. of the pure juice. The apples are cut into pieces, not crushed, and placed in the diffuser; and the water, which is passed through the apparatus, drives the juice before it. Fermentation is carried on at 12° to 18° C. (54° to 64° F.). If fermentation is slow the juice is stirred vigorously with a bunch of twigs; or in extreme cases, a little yeast is added. This first fermentation is carried on for five to six weeks in open or closed vessels, or in casks with the bung drawn. The bung is then driven in and a small vent-hole made, which is kept open by a straw. After a month or six weeks, during which secondary fermentation goes on, the liquor is drawn off into air-tight casks, which are not quite filled. The dregs that collect in this space may then be removed. If the cider be not quite clear, owing to insufficiency of tannin in the apples, 60 grms. of eachon dissolved in a litre of cold cider, are added to every hectolitre. This precipitates the albuminoids and prevents the cider turning black on exposure to air. Jersey cider has the reputation of being the best. The process employed differs slightly from the one given. The primary fermentation takes place in open vessels at 15°—18° C. The liquor is then drawn into casks which are not quite filled. When sufficient gas has collected in the empty space to extinguish a candle, the juice is drawn off into other casks, and the process is repeated till no more gas forms. Champagne cider is of recent introduction and owes its popularity to its sparkling quality and great stability. A cider is prepared that will keep in cask for five or six years, and can be exported to India or South America. It contains from 10 to 11 per cent. of alcohol. Before fermentation 50 grms. of cream of tartar and 500 grms. of green beech chips are added to every hectolitre. After fermentation the cider is heated by means of an anethiome and instantly cooled again. This apparatus costs about 16*l*. The process, however, is said to injure the flavour and quality of the cider.

The total quantity of cider produced in France in the year 1887 amounted to 295,606,674 gallons, as compared with 182,616,676 gallons in the preceding year.—H. T. P.

#### *Researches on the Germination of some of the Gramineæ.*

Part I. H. T. Brown and G. H. Morris. Proc. Chem. Soc. 1890 (81), 52—57.

In this, the first part of their paper, the authors confine themselves almost entirely to a consideration of the changes which take place in barley during the early periods of its growth. The paper is divided into 21 sections, the heads of which are as follows:—

(1.) Introduction. (2.) Structure of a grain of barley. (3.) The visible changes which occur in the embryo and endosperm during germination. (4.) The relation of the embryo to the endosperm. (5.) Development of excised embryos upon foreign endosperms. (6.) The endosperm to be regarded as a store-house of *dead* reserve material; no residue vitality recognisable in its cells. (7.) Cultivation of excised embryos upon water. (8.) Cultivation of excised embryos upon nutrient solutions. (9.) Growth of excised embryos upon *starch*, and proof that an amylolytic (diastase) is secreted by the growing embryo. (10.) The secretion of diastase is localised in the "absorptive epithelium." (11.) The secretion of diastase is increased

by the presence of a small quantity of acid. (12.) The secretion of diastase not stimulated by the presence of starch. (13.) The secretion of diastase is inhibited by a readily assimilable carbohydrate. (14.) The existence of a *cellulose dissolving* enzyme (cyto-hydrolyst) in the germinating seeds of the Grasses. (15.) The cyto-hydrolyst, like diastase, is secreted by the "absorptive epithelium." (16.) The two varieties of diastase, their genesis and distribution in the resting and germinating seed. (17.) Distribution of diastase in the germinating seed. (18.) The "mother-substance" of the "diastase of secretion" is principally derived from the endosperm. (19.) Action of "diastase of secretion" upon ungelatinised starch. (20.) A consideration of the origin of the hydrolytic enzymes of germinated grain. (21.) The form in which the reserve starch after transformation enters the growing embryo, and the metabolic changes which it there undergoes.

In recording the visible changes which occur in the seed during germination, the authors show that a disintegration and dissolution of the cell-walls of the endosperm always precede any attack upon the cell-contents. This breaking down of the cell-wall is shown to depend on the production during germination of a special cellulose-dissolving ferment, which, like diastase, is soluble. The action of this enzyme on the cell-walls of some kinds of vegetable parenchyma is very energetic. The physiological importance of this soluble ferment is very great, for owing to the non-diffusible nature of diastase, the previous breaking down of the cell-wall is a necessary prelude to the dissolution of the contained starch-granules.

The authors show that the appearance of the cyto- and amylolytic ferments is due to a specialised secretory function of the layer of columnar epithelium, which covers the outer surface of the scutellum. It has hitherto been considered that the function of this epithelium was exclusively that of an absorptive tissue; its absorptive as compared with its secretory functions are, however, of quite secondary importance.

Starch has no special power of stimulating the cells of the epithelium to increased secretion of a diastase, and carbohydrates which are readily assimilable by the embryo, like cane sugar or maltose, check or completely inhibit the secretion of diastase. Carbohydrates, like mannitol or milk-sugar, which are entirely without nutritive value, exercise no such inhibitory action. The authors' experiments point to the secretion of the enzymes being to some extent *starvation phenomena*.

The authors confirm the important generalisation of Sachs, that the relation of the embryo to the endosperm is that of parasite to host, and they have availed themselves of the relation by cultivating the embryo upon suitable media after separating it from its endosperm, and in this way they have obtained information with regard to the secretory powers of the embryo, and the chemical modifications of its absorbed nutriment, which it would have been impossible to obtain by any other means. They show, for instance, that whilst cane-sugar, invert-sugar, dextrose, levulose, maltose, raffinose, galactose, and glycerol have all more or less nutritive value, milk-sugar and mannitol have no such value. Cane-sugar has the greatest nutritive power; maltose is decidedly inferior to cane-sugar in this respect. This is shown to be due to the fact that maltose, directly it is absorbed by the growing embryo, becomes transformed into cane-sugar by the living cells, and in this form is passed from cell to cell.

An examination of the sugars produced during the germination, and of their mode of distribution in the grain, have convinced the authors that the transformed starch of the endosperm is absorbed by the embryo in the form of maltose, and that the seat of production of the cane-sugar which germinated grain contains is the tissue of the embryo itself.

In the discussion that followed the reading of the paper, Professor Marshall Ward drew attention to the recent paper of Haberlandt, in which he maintained that the aleurone layer in the seeds of the Gramineæ and other families of plants, is the seat of the production of diastase. He also mentioned that the observations of Wortmann on the

behaviour of bacteria in a mixture of starch and proteids tended to confirm the authors' views regarding the secretion of enzymes.

Professor Green said that his observations led him to believe that in the case of the date the enzyme was probably located in the epithelial layer and not in the endosperm, whilst in castor-oil seeds both the endosperm and embryo appeared to be possessed of vitality.

Dr. Lauder Brunton commented on the resemblance between the embryo in highly organised plants and in animals. The embryo in both cases appeared to be purely parasitic.

Dr. Armstrong compared the action of protoplasm in converting maltose into cane sugar to that of phenylhydrazine in effecting the conversion of dextrose into levulose through the agency of the osazone.

In reply, Mr. Horace Brown said that the diastase developed during germination appeared to differ in important particulars from ordinary diastase. He also said that the experiments of Dr. Morris and himself did not favour the conclusion that the aleurone-layer had any marked diastatic power.—G. H. M.

#### Some Experiments on the Numerical Increase of Yeast Cells. A. J. Brown. Trans. Lab. Club, 3, 64—80.

THE author first states that in the experiments about to be described, he adopted the method of directly counting under the microscope the number of yeast cells, both before and after fermentation.

Having briefly mentioned the work of Pedersen, Delbrück, Durst, Hansen, Hayduck, and Foth, on the increase of "bottom fermentation" yeast under various conditions, the author mentions that no work has been done with "top fermentation" yeast, with the Burton type of which the whole of the experiments about to be described were performed.

The first experiments were made with a view of ascertaining what influence different strengths of ordinary hopped ale wort had upon the total increase of yeast cells when fermenting it. The experiments were carried out as follows:—

Three flasks were taken of a capacity of about 250 cc. To No. 1 flask was added 150 cc. of a filtered hopped ale wort, of the specific gravity of 1076.70. To No. 2 was added the same volume of the same wort which had previously been diluted with distilled water to the specific gravity of 1051.14. To No. 3 was added the same volume of the same wort but diluted to the specific gravity of 1025.57. To each of these flasks was added an equal volume of yeast. On well shaking the flasks and transferring a drop of the liquid to the haematimeter, it was found, on counting under the microscope, that each standard volume contained on the average 1.04 cells of yeast. The flasks were loosely plugged with cotton wool, immersed in a water-bath and kept at a temperature of 68° F. for three days, when all signs of fermentation were quite over. The flasks were removed from the bath, and, after being well shaken, a sample from each was placed in the haematimeter and the cells present again counted. It was now found that in each standard volume in No. 1 flask there were 21.52 cells; in No. 2, 20.24 cells; and, in No. 3, 14.80 cells. If from each of these numbers is subtracted the number of mother cells with which the fermentation was commenced (that is to say, 1.04), we find that in No. 1, 20.48 new cells have grown, in No. 2, 19.20, and in No. 3, 13.76. Hence it appears that, although the wort in No. 2 was only two-thirds the strength of that in No. 1 flask, yet the number of new cells formed is almost exactly the same; and further, although the wort in No. 3 flask was only one-third the strength of that in No. 1, yet the new cells formed are two-thirds the number of those in No. 1.

A second experiment was made with a different wort, in which No. 1 contained 100 cc. of the wort at the specific gravity 1106, and No. 2, 100 cc. of the same wort diluted with distilled water to the specific gravity of 1079.5. This experiment was conducted in the same manner as the previous one, with the result that at the conclusion of the fermentation No. 1 contained 34.10 new cells per standard

volume, and No. 2, 33.83. Here, again, we find two worts of rather high but different specific gravities, in which the total increase of the yeast had been the same. These experiments, and others which were made, all point to the conclusion that under the conditions of the experiments, worts exceeding some point near 1060 in specific gravity nourish the same number of yeast cells, and that below this specific gravity the number of cells formed is not in proportion to the specific gravity, but in a much higher one. These remarks, of course, only apply to a comparison of the same wort when diluted to different strengths. Worts brewed from different materials undoubtedly differ considerably from each other, as is seen when the results of the first two experiments are compared.

The above experiments having been made with malt wort, which contains both carbohydrate and nitrogenous yeast-food, it appeared desirable to conduct experiments in solutions in which either of these foods could be altered at will. In the first place experiments were made with yeast-water and varying amounts of dextrose, as follows:—

#### EXPERIMENT I.

No. 1.—100 cc. yeast-water containing 20 per cent. dextrose.....	Each flask yeasted with 1.23 cells pure yeast per standard volume.
No. 2.—100 cc. yeast-water containing 10 per cent. dextrose.....	
No. 3.—100 cc. yeast-water containing 5 per cent. dextrose.....	
No. 4.—100 cc. yeast-water containing 2 per cent. of dextrose.....	
No. 5.—100 cc. yeast-water containing no dextrose.....	

At the end of four days the fermentation was complete, and counting of the cells gave the following results:—

	Cells.
No. 1 contained.....	9.29
No. 2 ".....	10.02
No. 3 ".....	7.32
No. 4 ".....	5.40
No. 5 ".....	1.37

A second experiment was made with a stronger yeast-water and the following amounts of sugar:—

#### EXPERIMENT II.

	Per Cent.
No. 1.—100 cc. yeast-water, containing 30 dextrose.	
No. 2. " " " " 20 " "	
No. 3. " " " " 10 " "	

Each flask was yeasted with 1.92 cells pure yeast per standard volume. After fermentation, the total number of cells found was:—

	Cells.
No. 1.....	14.10
No. 2.....	14.02
No. 3.....	14.34

From these experiments it appears that the amount of the carbohydrate food here used does not influence the multiplication of the yeast at all when it exceeds 5 per cent.; and further, that below 5 per cent. the multiplication of the cells is not in proportion to the sugar present, but in a much higher one. The result in flask 5, Experiment I., shows that yeast-water alone does not encourage yeast increase at all.

The influence of nitrogenous food upon yeast increase was next examined. In the first experiment, varying strengths of the same preparation of yeast-water were used as the nitrogenous food, and the carbohydrate food was maintained a constant quantity.

#### EXPERIMENT I.

Flask 1 contained 100 cc. yeast-water.
Flask 2 contained 50 cc. yeast-water and 50 cc. distilled water.
Flask 3 contained 25 cc. yeast-water and 75 cc. distilled water.
Flask 4 contained 100 cc. distilled water alone.

The solution in each flask contained 10 per cent. dextrose, and was yeasted with 2.20 cells pure yeast. Fermented

four days at 72° F., and afterwards the total cells were counted, with the following results:—

	Total Cells.
Flask No. 1 .....	14'44
" 2 .....	12'01
" 3 .....	7'97
" 4 .....	3'57

A second experiment was made in which the nitrogenous food was represented by asparagin, which was dissolved in varying amounts in a 10 per cent. solution of dextrose in pure water.

#### EXPERIMENT II.

##### Per Cent.

Flask No. 1 contained 2'0 asparagin and 150 cc. sugar solution.

" 2	"	1'0	"	"	"
" 3	"	0'5	"	"	"
" 4	"	0'25	"	"	"
" 5	"	no asparagin	"	"	"

Each solution was yeasted with 3'05 yeast cells per standard volume. The total number of cells found after fermentation was—

	Total Cells.
Flask No. 1 .....	5'37
" 2 .....	6'13
" 3 .....	7'47
" 4 .....	6'80
" 5 .....	3'00

A third experiment was made in a similar manner to the preceding one, but in which meat peptone replaced the asparagin as nitrogenous food, all the other conditions being the same.

##### Per Cent.

Flask No. 1 contained .....	0'333 peptone.
" 2 .....	0'166 "
" 3 .....	0'083 "

The solution in each flask was yeasted with 3'22 cells per standard volume. After completion of fermentation, the following results were obtained:—

	Total Cells.
Flask No. 1 .....	6'33
" 2 .....	5'96
" 3 .....	5'41

It is evident from the above experiments that an increase in the amount of nitrogenous food does not cause a proportional increase in the number of yeast-cells formed, but points to the conclusion that beyond a certain concentration there is no further increase. Neither asparagin nor meat peptone can be regarded as favourable nitrogenous food for yeast.

An experiment made to ascertain what effect the amount of yeast introduced into a wort had upon the total number of cells found at the conclusion of the fermentation showed that, within reasonable limits, the amount of yeast originally introduced to start a fermentation in malt wort, has little or no influence upon the number of new cells at the conclusion of fermentation, but that the number will be the same in the same volume of wort.

An experiment made to determine if different volumes of the same solution nourished the increase of yeast cells in the same proportion as their bulk showed that the increase of yeast was almost exactly *directly as the volume of the solution*.

The following experiment was made to ascertain, at intervals during a fermentation, the rate of increase of the yeast cells, and also the amount of sugar fermented by them. For this purpose a flask, containing 250 cc. of yeast-water, in which was dissolved 56'35 grms. of dextrose, was sterilised by heat in the usual way and inoculated with 1'39 cells of pure yeast per standard volume. At intervals of 24 hours for the first five days of fermentation, and afterwards at intervals of 48 hours, the flask was well shaken and a sample withdrawn, in which was determined the number of yeast cells, and also the amount of sugar unfermented. The following table gives the results obtained:—

Fermented at 68° F.	Total Cells Found.	Dextrose Fermented.
Started—		
May 30th, 11 a.m....	1'39	None.
May 31st, 11 a.m....	8'46 (3'70)	3'70 grms. per 100 cc.
June 1st, 11 a.m....	15'02 (3'35)	7'05 " "
June 2nd, 11 a.m....	16'79 (3'98)	16'98 " "
June 3rd, 11 a.m. ..	18'06 (4'47)	15'45 " "
June 4th, 11 a.m....	17'92 (1'82)	17'27 " "
June 6th, 11 a.m....	18'45	20'38 " "
June 8th, 11 a.m....	18'04	21'84 " "
June 10th, 11 a.m....	18'72	22'01 " "

In the above table the figures in brackets represent the weight of sugar fermented each 24 hours.

It is very generally supposed that during fermentation the yeast cells split up sugar into alcohol and carbonic acid most rapidly during a late period of their growth, or when their growth has already ceased, and that during the very early stages of growth but very little sugar is fermented; but the results of the experiments given in the above table appear to contradict this idea, for it will be noticed that at the end of the first 24 hours, when 8'46 cells are found in the liquid, 3'70 grms. of sugar had been fermented away. At no other time during the fermentation was anything like this proportion of sugar fermented by a similar number of cells. For instance, at the end of the fourth day of fermentation, we find that 4'47 grms. of sugar have been decomposed in the previous 24 hours; but we find that 18'06 cells have been in the liquid during this time; obviously, therefore, the 8'46 cells present during the first 24 hours have done far more work in decomposing 3'70 grms. of sugar, than 18'06 cells in decomposing 4'47 grms.

The above experiment is open to the objection that the flask was shaken every 24 hours in order to distribute the yeast before taking a sample, and as agitation has a great influence in promoting yeast growth, the experiment was repeated as follows:—

Six flasks were taken similar in size and shape, and to each was added 150 cc. of the same yeast-water solution, containing 18 per cent. dextrose. To each flask was added an equal amount of yeast, amounting to 0'65 yeast-cell per unit volume. All the flasks were then fermented under precisely the same conditions, and one flask withdrawn every 24 hours for examination, leaving the remaining flasks at rest. The results obtained are given in the following table:—

	Total Number of Cells.	Total Grms. Alcohol in 100 cc.	Mean Number of Cells present during each Interval of Time.	Grms. Alcohol in 100 cc. formed during each Interval of Time.	Proportion of Grms. Alcohol per 100 cc. to a Single Cell, in each Interval of Time.	Interval of Experiment.  Hours.
January 9, 11 p.m. ....	0'65	" "	" "	" "	" "	" "
January 10, 11 a.m. ....	4'87	0'654	2'76	0'654	0'237	12
January 10, 11 p.m. ....	12'03	1'933	8'45	1'279	0'1513	12
January 11, 11 a.m. ....	15'38	2'975	13'70	1'042	0'0760	12
January 12, 11 a.m. ....	15'88	4'237	15'63	1'262	0'0807	24
January 13, 11 a.m. ....	15'80	6'187	15'80	1'350	0'1234	24

It will be noticed, on examining the table, that the results found quite bear out the conclusion arrived at from the first experiment, viz., that yeast cells at an early period of their growth ferment sugar much more rapidly than at a later period.

An experiment made upon malt wort and carried on in a similar manner to the above, gave results which quite confirm this conclusion.

The author also quotes an experiment taken from a paper by Hansen, which also confirms this result.

A. J. Brown draws the following conclusions from his work :—

1. Similar volumes of the same malt wort, varying in strength, but exceeding the specific gravity of 1060°, encourage the growth of equal numbers of yeast cells; in the same malt wort, below the specific gravity of 1060°, the increase in number of yeast cells is not in proportion to the specific gravity, but in a much higher proportion.

2. An increase of sugar (dextrose) in a fermenting liquid beyond 5 per cent. does not increase the number of yeast cells formed; below 5 per cent. of dextrose the increase in number of cells is not in proportion to the strength of the sugar solution, but in a much higher proportion.

3. Nitrogenous food, when beyond a certain concentration in a fermenting liquid, appears not to increase the multiplication of yeast cells; below this concentration the multiplication is not in proportion to the nitrogenous food present, but in a much higher proportion.

4. The quality of yeast food determines a greater or less increase of yeast cells.

5. The number of new cells formed in a fermenting liquid is independent of the number of mother cells originally introduced, when these do not exceed certain limits.

6. The total number of yeast cells found in different volumes of the same fermenting liquid is *directly in proportion to the volume*.

7. Fermentation of sugar is most rapid during the earliest stages of yeast increase, and least rapid when the increase has ceased.

8. Fermentation is carried on by yeast cells for a long time after their increase in number has ceased.—G. H. M.

*On the Analysis of a Beer of the last Century, with some Remarks upon the Estimation of Amyloins (Maltodextrins) in Beer.* H. T. Brown and G. H. Morris. Trans. Lab. Club, 3, 81—98.

THE beer in question was brewed at Burton-on-Trent in or about the year 1798.

It is a strong ale, and although still perfectly sound, has to a great extent lost the general character of a beer during the long years it has been in bottle. Its chief characteristic is the extraordinary bouquet it possesses, which strongly resembles that of old Madeira. This bouquet is due to compound ethers which have been developed in considerable amount. When the sediment is examined under the microscope, it is seen to be made up for the most part of finely-divided amorphous matter, but here and there undoubted evidence of yeast cells have been obtained. These are very shrivelled in appearance, but on one or two occasions the authors have suspected the presence of a few yeast cells still retaining vitality, and in these cases the beer was still charged with gas. No bacterial growth has ever been observed.

The following is an analysis of the old beer, and also, for purposes of comparison, that of a strong ale of about the same gravity, but of an age of only 18 months. The results are expressed in percentages on the total solids present before fermentation, deduced from the original gravity by the 3.86 divisor.

	Old Ale. (90 Years Old).	New Strong Ale. (18 Months Old).
Specific gravity at 60° F. .	1030.45	1030.47
Original specific gravity .	1110.38	1103.58
Solid matter per 100 cc. .	28.595 grms.	26.782 grms.
Alcohol by weight . . . . .	8.70 per cent.	7.85 per cent.
Total acid (calculated as acetic acid) . . . . .	0.6605 „	0.3635 „
Volatile acid (calculated as acetic acid) . . . . .	0.1101 „	0.2095 „
Fixed acid (calculated as lactic acid) . . . . .	0.7038 „	0.2400 „
Volatile compound ethers (calculated as acetic acid) . . . . .	0.0598 „	0.0334 „
Percentages on original wort solids:—

In these analyses the authors have expressed a portion of the carbohydrate constituents as *amyloins*, and it is with the determination of these substances that the new method has to do. Before describing the details of the method, the authors furnish the following explanation of the term, and of the position which the substances occupy with regard to the other transformation products of starch.

In a paper read by them before the Chemical Society in 1885 (this Journal, 1885, 682), they described a substance, under the name of *maltodextrin*, which occurs in all starch transformations to a greater or less extent; and in a later paper (this Journal, 1889, 716) they described a substance of a similar nature under the name of *amylogdextrin*. The distinguishing characteristics of these substances are:—

1. That they give numbers on analysis which allow their composition to be expressed in terms of a mixture of maltose and dextrin.

2. That they cannot be separated by any known means into maltose and dextrin, and are, therefore, compound bodies.

3. That they are completely converted into maltose by the action of malt-extract or diastase.

4. That they are unfermentable during the primary fermentation.

A closer study of the products of the transformation of starch has convinced the authors that there are a considerable number of these bodies, and in their latest paper dealing with the subject (this Journal, 1889, 717) they recognise the existence of “maltodextrins, whose number is only limited by the size of the original amylin group,” from which they are derived. It is these substances which Brown and Morris now propose to name *amyloins*, a term suggested by Armstrong, and one which expresses their truly compound nature as distinguished from a mixture of maltose and dextrin.

In considering the position which these bodies hold with regard to the other transformation-products of starch, the authors state that in their last paper they expressed an opinion, based upon their more recent experiments, that the dextrins can no longer be regarded as constituting a polymeric series, but that the starch molecule, in the first moment of

hydrolysis, breaks down into five amylin groups of equal magnitude. One of these amylin groups resists, to a much greater extent than the other four groups, the hydrolysing influence of diastase—this constitutes the stable dextrin which has been so often described as that of the No. 8 equation. The remaining four amylin groups are capable of gradual and complete hydrolysis to maltose, a series of intermediate amyloins of varying degrees of complexity being produced, the general tendency being for the molecular aggregations to become less as the hydrolysis becomes more complete, until the final stage of maltose is reached.

It follows from this that in a starch conversion which has proceeded to any extent—such a one, for instance, as takes place in the mash-tun—the products of the conversion consist therefore of free maltose, of free dextrin, which is not further hydrolysed, and of a series of amyloins of varying constitution.

When a beer which has undergone a normal fermentation reaches the racking stage, it is found on examination that, although it still apparently contains a very considerable amount of maltose, judging from the cupric reducing power, yet it undergoes but little or no further fermentative change until the secondary fermentation commences, or until malt-extract is added. In a word, a normal beer, when racked, contains little or no free maltose, the apparent maltose in the beer existing for the most part as amyloins, which require to be degraded before they become fermentable. On storage, degradation gradually takes place under the influence of the secondary yeast-forms, free maltose is liberated and fermentation starts once more.

From what has been stated above as to the properties of amyloins, it is evident that if the free maltose can be removed from a beer, the unfermentable maltose will represent the amylin portion of the amyloin, and further, that if the beer residue is degraded with diastase under favourable conditions, the increase in maltose so produced will be a measure of the amylin portion of the amyloins.

The details of the method which Brown and Morris propose for the determination of amyloins, and which they employed in the analyses given above, are as follows:—

The original gravity of the beer, the optical activity, and the cupric-reducing power are determined in the usual way (see Heron, this Journal, 1888, 272).

250 cc. of the beer are then taken, the greater portion of the alcohol is distilled off, and the residue is made up to the original volume. The results of the subsequent determinations can then be calculated on the original gravity of the beer.

100 cc. of this residue are set to ferment at 80°–85° F. with a very little pressed and washed yeast. When the fermentation, if any, is complete, the liquid is cooled, made up to the original volume, and the optical activity and cupric-reducing power determined. The difference between these numbers and those obtained for the original beer represents the amount of free maltose originally present in the beer.

A second 100 cc. are degraded at 120°–125° F. for one hour with a sufficient quantity of malt-extract or precipitated diastase, preferably the latter, in order to degrade the amyloins. The degraded residue is then boiled, cooled, and made up to the original volume; the optical activity and reducing power are again determined, and the difference between these numbers (after correcting, if necessary, for malt-extract) and those obtained before degradation, is a measure of the conversion of the amylin or dextrin portion of the amyloins into maltose.

The method of calculating these results will be best seen in the following example, which shows the results obtained by this method with a pale ale undergoing cask fermentation:—

#### Original gravity—

Residue .....	1026.74
Degrees of gravity lost, deduced from spirit indication .....	34.30
Original gravity .....	1061.04

Original wort solids per 100 cc. ....	15.813 grms.
Solid matter fermented .....	8.886 "

#### Analysis of residue—

Opt. act. in 200 mm. tube .....	43.4 divs.
Copper oxide reduced per 100 cc. 2.924 grms. = 1.610 grms. maltose.	

#### Residue after fermentation—

Opt. act. in 200 mm. tube .....	39.2 divs.
Copper oxide reduced per 100 cc. 2.171 grms. = 1.610 grms. maltose.	

#### Residue after degradation—

Opt. act. in 200 mm. tube .....	39.6 divs.
Copper oxide reduced per 100 cc. 3.814 grms. = 2.830 grms. maltose.	

The solid matter fermented divided by the original wort-solids gives the matter fermented, which expressed as a percentage on the original wort-solids is  $\frac{8.886 \times 100}{15.813} = 56.19$  per cent.

The free maltose is found by subtracting the maltose found after fermentation from that in the original beer, thus:— $2.170 - 1.610 = 0.560$  grm. free maltose per 100 cc., expressed as a percentage on the wort-solids this is  $\frac{0.560 \times 100}{15.813} = 3.54$  per cent.

The maltose found after fermentation represents that present in combination as amyloins, the percentage in this case being  $\frac{1.610 \times 100}{15.813} = 10.18$  per cent maltose as amyloins.

The amylin or dextrin portion of the amyloins is found by subtracting the maltose in the original beer from that found after degradation; the small difference due to fixation of water being neglected as falling within the errors of experiment, thus:  $2.830 - 2.170 = 0.660$  grm. dextrin, or as a percentage  $\frac{0.660 \times 100}{15.813} = 4.17$  per cent.

In order to obtain the free dextrin, the deflection due to the maltose found after degradation is calculated and subtracted from the total deflection, the amount of dextrin corresponding to the residual deflection is then calculated in the usual way, thus:  $2.830 \times 7.813 = 22.11$  divs. deflection due to maltose; then  $39.6 - 22.1 = 17.5$  divs. deflection due to dextrin; and  $17.5 \div 11.25 = 1.555$  grm. of dextrin; or, expressed as a percentage,  $\frac{1.555 \times 100}{15.813} = 9.83$  per cent.

The total amount of amyloins is of course obtained by adding together the maltose and dextrin present in this form.

#### The complete results are therefore:—

Fermented matter .....	56.19
Free maltose .....	3.54
Free dextrin .....	9.83
Amyloins:—	
Containing maltose .....	10.18
dextrin .....	4.17
Undetermined matter .....	14.35
	16.09
	100.00

It will be noticed that in the above, the results are calculated from the copper oxide determinations, as far as the original beer and residue after fermentation are concerned, and not from the polariscope readings. The authors consider that in this case the former determinations are capable of being made with greater accuracy than the latter, owing to the dilution required to obtain a good reading, and also to the comparatively small differences in reading which are caused by the conversion of dextrin into maltose. The opticity determinations may be used as a control to the numbers obtained from the copper oxide determinations.

Brown and Morris state that the method may be employed for the analysis of malt-worts, and also for the comparison of different malts mashed under identical conditions; in these cases the amount of free maltose will be large, and will require to be corrected for the ready formed sugars of the malt. It is also advisable to take the residue after complete fermentation of the free maltose for the determination of the amyloins.

In conclusion, they draw attention to the very different types of amyloins which are present in the three beers, the analyses of which are given above. In the old strong ale the mean ratio of  $\frac{M}{D}$  is 4.9:1 (dextrin being taken as unity); in the new strong ale the ratio is 1.7:1; and in the pale ale the ratio is 2.4:1. The authors consider that it is probable the closer study of the ratio of maltose to dextrin in the amyloins in beer will throw much light on the conditions of after-fermentation.

They state that there can be no doubt that the amyloins play a most important rôle in the manufacture of beer, forming, as they do, a store of carbohydrate material, which only slowly becomes available for fermentation as it is gradually hydrolysed. The recognition of their presence also explains much that was formerly obscure in the conditioning of beer; in fact, it may be said, with a tolerable amount of certainty, that if it were not for the existence of such bodies, the long-continued after-fermentation of beer would be an impossibility, and our popular beverage would be something very different from what it now is.

—G. H. M.

*The Influence of Germination upon the Constituents of Barley.* J. O'Sullivan. Trans. Lab. Club, 3 (5), 1890.

THE author divides the constituents of barley and of germinated barley into two groups, those that are soluble in cold water and those that are insoluble in that medium.

In barley the following bodies comprise the first or soluble group:—

- Cane sugar.
- Dextrose.
- Levulose.
- Albuminoids.
- $\beta$ -amylan and other carbohydrates.
- Mineral matter.

To these, in the case of germinated barley, must be added maltose, whilst in the ungerminated grain, raffinose is sometimes found (C. O'Sullivan, Jour. Chem. Soc. 1886, 70).

The second, or insoluble group, in each case consists of—

- Fat.
- Starch.
- Cellular matter.
- Casein (vegetable).
- Cellulose.
- $\alpha$ -amylan.
- Mineral matter.

The chief change involved in the germination of barley is that of diminishing the constituents that are insoluble in cold water, and, at their expense, increasing those that are soluble. This is the direction in which we would naturally expect the change to take place, and not the other way about, for we could not imagine insoluble bodies circulating in the cells, or from cell to cell of the embryo plant. The insoluble bodies in the endosperm, or starchy portion of the grain, which are meant by nature to nourish the young plant, must be made soluble before it can make use of them, or, in other words, they must be brought into circulation by what is in reality a digestion process. The quantity of insoluble substance of barley is considerably diminished by germination; a part of this appears as an increase in the soluble substance of the germinated barley, another appears in the form of rootlets, and the remaining part is consumed during the respiration of the embryo to produce water and carbonic anhydride.

The ratio the carbon oxidised bears to the water liberated points to the oxidation of a glucose; it is not, however, improbable, judging from the bodies that are altered in quantity at an early stage of the germination, that the carbon oxidised is obtained from other sources.

The cane-sugar, or saccharose, is considerably increased during the germination, and as its inversion products, levulose and dextrose, are essential food matter for the young plant, the production of cane-sugar, and its inversion, together with the consumption of the products of its inversion, must be going on at the same time during the

growth of the barley. The aqueous extract of green malt contains no cane-sugar, but the extract of dried malt, if quickly made (two to three hours' extraction), contains cane-sugar; this, however, is not the case if the extraction extends to 10 or 12 hours.

The invertive ferment, or invertase, as already observed by Kjeldahl, occurs chiefly in the rootlets of germinated barley, and from experiments made to determine in what part of the germinating grain, besides the rootlets, this ferment is most abundant, it is found to be exclusively confined to the germ end. The quantity of invertase either in the rootlets or in the germ end is very variable. The following experiments show this.

Digestions were carried on in the cold, with a cane-sugar solution for 24 hours. The rootlets were obtained from samples of the same barley grown at different times, but apparently under like conditions and at the same age of growth.

- 1.7 grms. of moist rootlet (removed from 35 grms. barley) inverted 1.22 grms. cane-sugar.
- 0.5 grm. of moist rootlet (removed from 10 grms. barley) inverted 1.37 grms. cane-sugar.
- 0.5 grm. of moist rootlet (removed from 9.1 grms. barley) inverted 0.15 grm. cane-sugar.

The following results will show pretty forcibly the greater invertive power of the rootlets when in contact with the cane-sugar solution.

The extract obtained from 0.5 grm. of rootlets, by digesting with water in the cold for two hours, when further digested with cane-sugar solution for 24 hours, gave no inversion. Under similar conditions, but in contact with the sugar, 0.5 grm. inverted 1.37 grms. of cane-sugar.

Invertase being more active at about 55° C. than in the cold, experiments were made to determine the invertive power of rootlets at that temperature, and also to learn if, after extraction with cold water, they retained their invertive power when placed in contact with cane-sugar solution: (1) 0.75 grm. of rootlets was digested in the cold for two hours with about 10 cc. of water; then filtered out and washed on filter till filtrate and washings amounted to 50 cc. To 46 cc. of this extract 25 cc. of a 10 per cent. cane-sugar solution were added. (2.) The residual rootlets on the filter were added to another 25 cc. of the sugar solution. (3.) 0.75 grm. of the same rootlets was added to a third 25 cc. of the sugar solution; digested at 55°—57° C. for eight hours, and after standing for eight hours longer in the cold made up to 100 cc. The cane-sugar inverted, and calculated from the cupric oxide reducing power of each 100 cc., is shown as follows:—

Experiment I.—

Extract of 0.75 grm. rootlets inverted 0.19 grm. sugar.

Experiment II.—

Residual rootlets of Experiment I. inverted 1.90 grms. sugar.

Experiment III.—

Original 0.75 grm. rootlets inverted 1.69 grms. sugar.

The cupric oxide reducing power of the extract of the rootlets was allowed for in I. and III. experiments, and was obtained from the 10 cc. kept out of the 50 cc. extract.

The results of a repetition of these experiments, with a different growth of rootlets, but allowing the original rootlets to remain in contact with a little water for the same time as that digested and extracted in the cold, are as follows:—

Experiment I.—

Extract of 0.106 grm. rootlets inverted only a trace cane-sugar.

Experiment II.—

Residual rootlets of Experiment I. inverted 0.45 grm. cane-sugar.

Experiment III.—

Original rootlets 0.106 grm. inverted 0.35 grm. cane-sugar.

The results show that the extracted rootlets retain their inverting power, in fact they come out here more active than the original rootlets; however, much cannot be said about this difference, as it may be due to the difficulty of proper sampling.

It is clear, from these experiments, that nature has arranged that the invertase, which must be of vital impor-

tance to the young plant, should not be easily dissolved by water, and it is more than probable that no invertase is dissolved from the rootlets of the growing grain in any appreciable time.

The following results show that the invertase was exclusively confined to the germ end:—

A number of grains, weighing 9.4 grms., of the same air-dried germinated barley as that from which the rootlets in the last-mentioned experiments were obtained, were cut in two. The germ ends, weighing 4.21 grms., were very finely pulverised, and 1.82 grms. of this was added to 25 cc. of a 2 per cent. cane-sugar solution, the remainder being added to about 25 cc. of water. The acrospires were carefully removed (avoiding any starchy matter) from 80 grains, weighing 3.7 grms., of the same growth of barley. These weighed 0.188 gm. They were placed in a 25 cc. flask, which was then filled with the 2 per cent. sugar solution.

All three were digested for 16 hours at 45°—50° C. In the first two experiments the residue was filtered out, and washed on filter, till filtrate and washings amounted to 50 cc.; in the last experiment the solution was made up to the original volume.

A determination, by the optical and cupric oxide reducing method of analysis, gave the following results for the cane-sugar inverted in the digestions with the germ end and acrospire. The results obtained in both experiments were corrected by those of blank or duplicate experiments with water:—

1.82 grms. germ end (4.0 grms. original grain) inverted 0.2 gm. cane-sugar.

0.118 gm. acrospire (3.7 grms. original grain) inverted 0.21 gm. cane-sugar.

The quantity of dextrose in germinated barley was always found to be in excess of the levulose, but it was not uncommon to meet with some which showed no evidence of the presence of maltose, yet cane-sugar was never absent.

The insoluble nitrogenous matter of the barley was considerably diminished, and found to be an important property imparted either to the nitrogenous matter already soluble in the barley or to that rendered soluble by the germination—namely, high diastatic power.

Rootlets contain a very high amount of nitrogen, as much as 3.5 to 4.0 per cent. having been found in them, which, if calculated as albuminoid, amounts to 21.8 to 25.0 per cent. Asparagin has been isolated from rootlets, and if the nitrogen be taken to be due to this body, we shall find from 16 to 19 per cent. are present in the dry rootlet. The quantity of nitrogen in the rootlets shows the amount that diffuses in a soluble form from the endosperm through the scutellum during germination. About half of the nitrogenous matter of rootlets is soluble in water, and none of this is coagulable. This soluble non-coagulable portion is probably asparagin, and the insoluble portion is most likely vegetable casein.

The quantities of  $\alpha$ - and  $\beta$ -amylase are diminished during germination. So are also the inorganic or mineral constituents of barley soluble in water, and which are chiefly composed of potassium phosphate.

The fat of barley is diminished during germination, and evidently being a suitable body to take part in the early respiration of the embryo, its diminution is observed at an early stage of the germination.

Starch supplies the largest amount of food of any of the constituents to the embryo. It is diminished and it gives rise to the soluble sugar maltose which is produced from the starch by the diastase developed in the seed by germination. Dextrin is not present in germinated barley (C. O'Sullivan, Jour. Soc. Arts, 1876). It is probable that in the solution of the starch dextrin is produced; however, at the period of germination, when the starch begins to be dissolved, there is present in the germinating grain an excess of diastase, which converts the dextrin immediately into maltose.

Besides barley, wheat, rye, maize, and oats were found to possess a diastatic power as well.

In order to determine if this power increases in that part of the endosperm farthest removed from the embryo, the following experiments were made:—

Some sound barley, after being steeped, was allowed to germinate. At the end of the first day 20 grains which

showed signs of germination were taken and cut transversely in two, leaving about two-thirds of the grain with the germ end, which was neglected. From the other one-third, which I shall call the endosperm end, the starchy portion was removed (avoiding that near the husk) and pulverised in a mortar. The pasty mass thus obtained was mixed with about 25 cc. of cold water; this mixture was gradually heated to 65°—68° C., and kept at that temperature for 12 hours. It was observed that although the starch was not dissolved, yet there was an undoubted tendency in this direction, as compared with a similar experiment by its side made with the original barley. This experiment was repeated from day to day during germination, with the following results:—

Days of Germination.	Appearance of Solution.	Result.
First	Inclination to dissolve; no "break" in solution.	Soluble starch present in filtrate of a portion cooled.
Second	Decided solution, but no "break."	Ditto.
Third	Decided solution and "break" or precipitation of flocculent albuminoid and cellular matter.	No soluble starch, but $\alpha$ -dextrin, &c.
Fourth	Complete solution and "break," leaving solution quite bright.	In 20 minutes neither soluble starch nor $\alpha$ -dextrin.

Similar results were obtained for germinating oats.

The time of digestion for the third day's experiment was only three hours. The rootlets, even on the fourth day of growth, were only 1 to 2 mm. in length, and the acrospire had scarcely started.

The production and presence of naked diastase in the endosperm, stimulated by the growing embryo, was considered by the author to be the most reasonable explanation for all the facts relating to the germination of barley.

By the cellular matter mentioned in the insoluble group, it is meant the constituent of the cells, which is pretty easily acted upon by boiling dilute acids this constitutes a portion of the endosperm of barley as may be seen if the endosperm is dissolved in the usual manner by malt extract; the starch goes into solution leaving the insoluble cellular matter as a flocculent structureless body. It is not, however, confined to the endosperm. It is diminished during germination, becoming soluble, and its metamorphosed form supplies the embryo with nutrient matter probably in the form of a sugar.

The casein is diminished during germination. This body is not dissolved by malt-extract, it is soluble in dilute alkalies, and is precipitated by acids from its alkaline solutions; it has, in fact, the properties of the casein of milk.

The cellulose proper of barley is chiefly located in the husk or palea; it is the most insoluble of the organic constituents. It is not altered in quantity during the period of germination, and probably is not touched even when the plant has developed to the stage when the whole of the contents of the endosperm are exhausted, and it is capable of assimilating for itself.

The results arrived at by the author are (1) that the diastase ferment originates in the endosperm, and (2) that the ferment capable of inverting cane-sugar is situated, where it is wanted, in the acrospire and rootlets.

The author is of opinion that the soluble metamorphosed contents of the endosperm, being produced in the cells of the endosperm of the growing barley-corn, are repelled, and diffuse through the scutellum towards the point of least concentration, which must be in the vicinity of the embryo or point of their consumption.

*Denaturation of Spirit.* G. Lunge. Zeits. f. angew. Chem. 1890, 71—72.

It has been stated in an article by A. W. von Hofmann, Krämer, and Löwenherz (Chem. Ind. 1889, 521) that the Swiss are using a "pyridine mixture" for denaturising spirit. As by this is understood a mixture of wood spirit and pyridine bases, the author takes the opportunity to assert that wood spirit is not used. Work on the subject is in progress.—T. L. B.

*The Denaturation of Spirit.* A. W. von Hofmann, G. Krämer, and L. Loewenherz. Chem. Ind. 13, 119—120.

A REPLY to the statement of Lunge (preceding abstract) that the Swiss Commission have rejected the German denaturation mixture. It is stated that the Swiss Administration up to the end of 1889 purchased large quantities of pyridine bases.—T. L. B.

*Recent Methods of Spirit Purification.* Chem. Ind. 13, 106—108.

THE older methods were mainly useless as being unscientific and unreliable. More recently has been brought out, however, the capillarimetric and stalagmometric method of Tranbe (see this Journal 1889, 42).

The method of the "*Société Française des Alcools purs*" (this Journal, 1889, 57) has reference rather to the working up of first runnings. The first runnings obtained in the rectification of spirit contain chiefly aldehyde and acetone. They are treated in vats with a solution of an alkali bisulphite of 32° B., in such quantity that, after conversion of the whole of the aldehyde and acetone into their sulphites, a slight excess of free bisulphite is present. When butyl aldehyde is proved to be present, a little neutral sulphite is used, as forming a more stable compound than the bisulphite. The whole mass is then distilled without any separation being previously performed. The alcohol so obtained contains sulphurous acid, and is therefore distilled again in presence of a base. Thus from a cheap source aldehyde and acetone may be obtained, as well as a tolerably pure alcohol.

A process which has been much used is that of Bang and Ruffin (this Journal 1885, 506; 1887, 147; and 1888, 224). It depends on the taking up of the impurities from the diluted alcohol by petroleum ether.

Schmitt diminished the capability of alcohol to dissolve fusel oil by addition of potassium carbonate. Potassium carbonate solution was added as long as no "layering" was visible, and then the whole was treated with petroleum ether. In his experiments Schmitt obtained the following results:—

Strength of Alcohol in Vols. per Cent.	Fusel Oil in Vols. per Cent.	Volume of Spirit for Treatment.	Volume of Petroleum Ether used.	Potassium Carbonate Solution. (Sp. gr. 1.3.)	Fusel Oil in Vols. per Cent. after Treatment.	Decrease of Fusel Oil, in Vols. per Cent.
50	0.5	cc. 300	cc. 150	cc. 24	0.29	0.21
30	0.3	300	150	110	0.17	0.13
50	0.2	300	150	110	0.11	0.09
30	0.2	300	300	110	0.05	0.15
30	0.2	300	600	110	0.00	0.20

After removal of the petroleum ether more potassium carbonate is added to bring about "layering," and the upper layer of alcohol is then syphoned off, neutralised, and distilled.

Before Schmitt, however, Traube made use of potashes (this Journal, 1888, 449, 513, and 762; 1889, 559 and 995), and very good results have been obtained. Tranbe mixes, at a given temperature, the spirit with a potassium carbonate solution, whose specific gravity varies according to the strength of the spirit; for 80 per cent. spirit he uses a potassium carbonate solution of sp. gr. 1.24 at 70° C. By using 4—5 parts of the solution to one part of spirit a layer separates, which contains three-quarters of the fusel oil. By replacing the spirit and alkali taken up by the first layer, by pure spirit and potassium carbonate, another similar layer is obtained, and the quantity of fusel oil is still further reduced. The first layer obtained in each treatment contains most fusel oil, and consequently the first layers of the various batches are kept by themselves, and finally worked up like the raw spirit itself. The spirit, purified by this "layering" process, is finally distilled from the potassium carbonate.—T. L. B.

constituents, next in importance came isobutyl alcohol, and after that isopropyl and ethyl alcohols and traces of normal propyl and butyl alcohols.—A. L. S.

## PATENTS.

*A Method of and Appliances for the Collection and Utilization of the Carbonic Acid and other Products given off during the Process of all Fermentations.* C. R. C. Tichbourne, A. E. Darley, and M. F. Purcell, Dublin. Eng. Pat. 3707, March 2, 1889. *sd.*

THE fermenting vessel is hermetically closed and the gas from the atmosphere above the fermenting liquid is collected by a pipe with a funnel-shaped opening; the opening is capable of adjustment so as to collect from any height above the surface of the liquid; any other suitable contrivance may be used. The gas contains, besides carbonic acid, vapours of alcohol and ethers; the amount of these is much larger in distilleries than in breweries, as the fermentation in the former is carried out at a higher temperature; it is led through a scrubber fed with a spray of water, or in special cases, sulphuric acid, and the purified carbonic acid condensed by suitable pumps. When, besides carbonic acid, other volatile bodies are present in the purified gas they may be separated by successive partial condensations, and the products obtained at various pressures collected separately. The alcohols and ethers recovered in any of the above methods may be either returned to the fermented liquid or utilised in any other way. A sheet of drawings accompanies the specification.

—A. L. S.

*An Examination of Fusel Oil.* J. H. Long and C. E. Linebarger. J. Analytical Chem. 4, January 1890. (Reprint.)

THE fusel oil was from American distilleries who chiefly use corn and other raw grain. It had a specific gravity of 0.810 at 20° C. It was dehydrated and separated by fractional distillation as follows:—1 litre gave 17 cc., 80°—90°; 8 cc., 90—95°; 15 cc., 95°—105°; 30 cc., 105°—115°; 55 cc., 115°—120°; 95 cc., 120°—125°; 240 cc., 125°—130°; 515 cc., 130°—135°; 25 cc. loss and residue.

A careful examination of these fractions showed that active and inactive amyl alcohol were the most important

*Improvements in and Apparatus for the Purification of Alcohol or Aleoholic Liquors.* E. Luck, London. Eng. Pat. 9181, June 3, 1889. 8d.

THE alcohol vapour as it rises from the distillation of the mash is purified by being drawn by pumps through one or more vessels containing liquid hydrocarbon. These vessels may be conveniently of the shape commonly used for washing gases, and furnished with a jacket, which may be supplied with steam or water, so that the hydrocarbon may be heated or cooled to any convenient temperature. The washed vapours are then cooled by a suitable condenser. A sheet of drawings accompanies the specification.—A. L. S.

*Improvements in the Manufacture of Yeast.* J. Bruce, Glasgow. Eng. Pat. 15,772, October 8, 1889. 4d.

THIS invention principally relates to the manufacture of yeast for baking purposes. A solution of albumen is prepared by extracting raw grain with cold or slightly warm water; this solution is then peptonised, either after filtration from the raw grain or without doing so, by allowing to sour in the presence of a very little malt, or mineral acid and malt. The solution or mixture is kept at 100°–120° F. for about 15 hours, and then the heat brought up to 175° F. This solution is then added to a distillers' wort prepared in the usual way; when the raw grain has not been separated before peptonising it forms part of the mash; otherwise it is used in making a prior mash. If, after saccharification, the acidity is less than 0.25 per cent. lactic acid, a small quantity of spent wash is added. The liquid is fermented by adding to it a mash of barley and rye, which has been allowed to sour and is in active fermentation, the amount being about 5 per cent. of the principal wort. The yeast is skimmed off as it rises to the surface, and the alcohol distilled from the fermented mash in the usual way.

—A. L. S.

separated from the milk by means of one of the well-known forms of centrifugal separators; thus delivered it passes over a cooling apparatus, where it is reduced to a suitable temperature and conducted by a pipe into the churning apparatus. This consists of a jacketed cylinder, kept at a suitable temperature by the circulation of a refrigerating fluid; the internal periphery is provided with straight or curved ledges. A high-speed beater revolves in the axis of the churn, and the butter globules are thus separated from the milk and delivered into a tube, which forms a prolongation of the churning cylinder, and here by centrifugal force the lumps of butter are collected into a mass; the mixture of butter lumps and milk are delivered from the end of a receiving chamber.—C. C. H.

*Improvements in Preserving Fish, Birds, Poultry, or other Analogous Articles of Food.* W. Douglas, Glasgow, and J. Donald, Kilwinning. Eng. Pat. 20,614, December 23, 1889. 4d.

FISH, poultry, or other analogous articles of food are enveloped in a suitable covering placed in an ice-making machine, and frozen into a block of ice. So prepared they can be preserved for an indefinite period.—C. C. H.

*Improvements in the Method of and Apparatus for the Production and Preservation of Sterilised Milk.* A. Schmidt-Mulheim, Wiesbaden, Germany. Eng. Pat. 1326, January 25, 1890. 6d.

THE patentee describes four forms of vessels or flasks suitable for the sterilisation of milk; these are shown in the accompanying figures. The milk is heated by means of steam jets and kept boiling for about 15 minutes after it begins to bubble. Fig. 1 shows a flask fitted with a

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

### (A.)—CHEMISTRY OF FOOD.

#### PATENTS.

*Improvements in Apparatus for the Manufacture of Bread, specially relating to Bakers' Ovens and Sponge-Blenders.* J. Adair, Waterford. Eng. Pat. 18,771, November 23, 1889. 8d.

HEAT collecting chambers are constructed underneath the ordinary flues of an outside heating oven, and "metals" may be placed in any of the chambers in which heat is specially required.

To blend the sponge a moveable sponge-blender made of strained wires, rods or hoops, may be thrown into the dough machine. Drawings accompany the specification.—E. E. B.

*An Improved Bread.* H. Fairlie, Newton Stewart. Eng. Pat. 19,042, November 27, 1889. 4d.

THE ingredients employed are:—Minnesota straight flour, broad-leaved English bran, "baking soda," small bread dough, loaf sugar, American hard, extract of malt and salt. These are mixed in specified proportions. The dough thus obtained is allowed to ferment for at least two hours before it is baked.—E. E. B.

*Improvements in Apparatus for Producing Butter.* H. H. Leigh, London. From C. G. P. de Laval, Stockholm, Sweden. Eng. Pat. 20,232, December 16, 1889. 6d.

THE object of this specification is the continuous production of butter from new milk, so as to combine the processes of skimming and churning. The cream is

ground cap having a cotton plug *c* tightly pressed in after boiling. Fig. 2 shows a flask with the neck cut off slanting, the ground plug *b* is provided with a hole *c*, so that communication with the air can be cut off by turning the cap round. In Fig. 3 the cap *b* is provided as shown

with narrow flutings small enough in section to retain the water driven off by ebullition round the neck of the flask, and so form a seal. In Fig. 4 the ground cap is drawn out to a very fine orifice, and though not tightly sealed to the air it has been found that after sterilisation in such a flask milk will remain quite good for several days even in summer.—C. C. H.

*Improved Sterilising Apparatus.* J. F. H. Gronwald, and E. H. C. Oehlmann, Berlin, Germany. Eng. Pat. 1910, February 5, 1890. 8d.

THIS invention relates to apparatus in which the fluid is sterilised in the vessel used for storage, and which can be closed without admitting air, whilst it also allows the vessel to be filled to any desired height without any risk of the fluid being deteriorated, or of the bottle being burst through any increase of temperature. To effect this an air-tight expansion chamber is detachably connected with the storage vessel in such a manner that the air in one, and the fluid in the other are sterilised at the same time, the liquid during the process partly entering the chamber and afterwards flowing back on cooling. Arrangements are provided for closing the vessel without admitting external air. The space above the liquid being filled with sterilised air acts as a cushion, and prevents any damage to the vessel from the expansion of the liquid on an increase of temperature. (See also this Journal, 1890, 405.)—E. S.

*Improvements in the Manufacture of Whole-meal Bread, Biscuits, and other like Articles of Food.* H. W. Hart, London. Eng. Pat. 2658, February 14, 1889. 6d.

THE wheat is washed, then crushed (*not* ground), soaked in water for about two hours and then baked.—E. E. B.

*Improvements in Processes and Apparatus for the Preparation of an Extract of Coffee, and in the Utilisation of the By-Products.* G. Sonstadt, Cheshunt. Eng. Pat. 3172, February 22, 1889. 8d.

THE apparatus described herein consists of a boiler, and a digester or extractor, fitted with suitable condensing column connected with vessels packed with wool for the absorption of the more volatile products. The boiler is connected with the digester by means of a pipe reaching to the bottom of the latter vessel and provided at the end with a rose or strainer. The ground coffee, sometimes mixed with chicory, is placed on a perforated plate near the bottom of the condenser, and boiling water run in from a subsidiary boiler. The principal boiler is then started, charged with sugar and water, the steam passing into the digester; the volatile products are arrested in the condensing column whilst the aromatic compounds are arrested in the vessels packed with wool. The boiler is then allowed to cool, consequently the decoction contained in the digester passes back thereto. The operation may be repeated as often as is requisite. The decoction is then evaporated to dryness after being mixed with sugar, and the aromatic bodies arrested in the condensing column and by the wool. It is requisite that the evaporator as well as the digester should be provided with an agitating apparatus which can be used for breaking up the material operated on.—C. C. H.

*Improvements in the Manufacture of Aerated Bread and in Apparatus to be used in the Manufacture.* J. Childs, London. Eng. Pat. 3607, February 28, 1889. 8d.

SEPARATED milk is aerated and used for making the dough. The mixing apparatus is constructed so that the aerated liquid can be added to it first and the flour afterwards.—E. E. B.

*Improvements in the Manufacture of Aerated Bread.* J. Childs, London. Eng. Pat. 5728, April 3, 1889. 4d.

THE aerated liquid for making the dough is obtained by adding some ferment to a mixture of flour and water, and keeping the mixture at 80° F. for 10 to 12 hours, or by adding to water either hydrochloric acid and bicarbonate of soda or tartaric acid and bicarbonate of soda.—E. E. B.

## (B.)—SANITARY CHEMISTRY.

*Phosphorous Oxide.* T. E. Thorpe and A. E. Sutton. Proc. Chem. Soc. (82), 1890, 61—64.

PHOSPHOROUS oxide has a well marked physiological effect, and it is not improbable that the action hitherto attributed to phosphorus, especially as regards its influence on the glycogenic functions of the liver and on tissue change, may be really due to this substance. It is well known that persons employed in the manufacture of lucifer-matches are occasionally attacked by caries of the lower jaw; this is not due to the action of the phosphorus after absorption into the circulation, but to the direct effect of the fumes upon the bone itself; for it has been found that when a bone of an animal fed by phosphorus was exposed, no carious change took place; but if one were exposed to the fumes caries was produced, and amongst lucifer-match makers it has been noticed that only those who have carious teeth suffer from necrosis of the jaw (T. Lauder Brunton, *Pharmacology*, &c., 771). The fumes from phosphorus consist largely of phosphorous oxide; by drawing air over phosphorus without allowing it to ignite and passing the fumes through a narrow strongly cooled tube a deposit is obtained which melts with the warmth of the hand and gives the reactions for phosphorous oxide. Moreover, the smell of the product is identical with that of pure phosphorous oxide, and it is also identical with the peculiar smell noticed in a lucifer-match manufactory during the making and handling of the "composition" with which the splints are "tipped," and which hangs about the benches where the "boxers" are at work. It is highly probable, as Schönbein long ago surmised, that phosphorus vapour as such is odourless, and that the smell which phosphorus ordinarily possesses is a mixture of that of ozone and of phosphorous oxide.

*Sewage Decomposition in Streams.* J. H. Long. J. Analytical Chem. 4, January 1890. (Reprint.)

THE author has examined the rate and manner in which sewage is oxidised in a highly contaminated stream (the Illinois) flowing for over 30 miles without dilution, and then for a further total of 160 miles, making allowance for the amount and character of the dilution by tributaries. He finds that the oxidation of the organic matter, as determined by estimations of free and albuminoid ammonia, oxygen consumed, nitrates and chlorides, is very much more rapid in summer than winter, and that in a dry hot summer it is quickest. Nitrates and nitrites did not appear until after a flow of many miles.—A. L. S.

## PATENT.

*An Improved Process for Deodorising, Disinfecting, Precipitating, Drying, and Pulverising the Solid Portions of Sewage.* W. Astrop, London. Eng. Pat. 6219, April 11, 1889. 4d.

THIS specification described improvements on Eng. Pats. 11,901 of 1884 and 10,047 of 1886 (this Journal, 1885, 463), and their object is, after extracting the greater part of the water from sewage sludge or excreta, to render the manipulation of the remaining solid matter easier. Larger vacuum boxes than formerly specified are employed, and the solid matter yielded by the operation is passed between rollers, reduced to a cake-like form, and in its passage through the rollers mixed with sifted dry material, e.g., cinders, road sweepings, bone dust, &c.—C. C. H.

## (C)—DISINFECTANTS.

## PATENT.

*Improvements in Disinfectants, their Manufacture, and their use for General Purposes, for Treating Sewage, and for Protecting Vines against Mildew and Phylloxera.* F. W. A. Hille, London. Eng. Pat. 6411, April 15, 1889. 6d.

MAGNESIUM or calcium chloride is dissolved in boiling water, and to this solution is added and thoroughly incorporated therewith a solution of camphor made by dissolving 1 oz. of camphor in 2 oz. of alcohol. The proportions recommended are 5 lb. of the metallic salt to half a gallon of boiling water, to which is finally added  $\frac{1}{2}$  oz. of the camphor solution. Thorough incorporation is effected by agitation. When used for disinfecting drains or sewers one part of the solution is diluted with four parts of water; when used for dressing vines for the purpose set forth it is diluted with from five to ten times its volume of water.—C. C. H.

## XIX.—PAPER, PASTEBOARD, Etc.

*Sulphite Pulp in America.* Chemical Trade Journal, 1890, 303—304.

THE following abstract is from a letter on the above subject by Mr. Waldemar Thilmann, Kaukauna, Wisconsin, U.S.A., on March 13th, to the *Papier Zeitung*, No. 35, 1st May, 1890.

At the Thilmann Pulp and Paper Works, the Mitscherlich sulphite process is at work. The first mill using this process was started at Alpena, Michigan, in November 1886, with a daily output of 20 tons of 2,000 lb. per ton.

It interested him much to find out how the different kinds of wood would behave in the sulphite process, and he therefore allowed a boiler full of each of the following different woods to be digested, viz.:—Beech (*Fagus Syleatica* L), birch (*Betula Alba*), maple (*Acer Pseudoplatanus* and *Acer Platanoides* L), American larch (*Pinus Larix* L), aspen (*Populus tremula* L), black poplar (*Populus Nigra* L), red fir (*Pinus Picea*), spruce or white pine (*Pinus Abies*), yellow pine (*Pinus Sylvestris*).

The wood was freshly felled, and had a diameter varying from 5 to 8 in. It was cut into discs of  $1\frac{1}{4}$  in. thick, and then digested whole with a solution of  $5\frac{1}{2}$  B. by the Mitscherlich methods. All of these woods with the exception of the *Pinus Sylvestris* (which remained hard in the centre), were well-boiled and completely soft.

Beech, birch, and maple yielded snow-white sulphite pulp, whose fibre, however, was considerably shorter than that from the red or white pine (*Pinus Picea* and *Pinus Abies*), and consequently they did not yield so strong a paper.

Afterwards, some boilers full of larchwood ("Tanræck") were digested, and the pulp run off on a cylinder machine in the same way as it is sent to the paper mills. The fibre appeared good and strong, but the colour was mottled, i.e., it varied from dark brown to citron yellow.

At present the seven mills in America, working the Mitscherlich system, produce daily about 70 tons pulp, and use exclusively spruce or white pine wood (*Pinus Abies*).

Two larger mills, situated in the Fox River Valley, with eight digesters, each 14 ft. diameter and 42 ft. long, produce daily 20 tons of pulp; whilst another mill at Madison, Maine, has 20 digesters of the above size, equal to a daily output of 20 tons pulp.

Sulphite pulp prepared by the Mitscherlich process is clean if the wood be properly sorted. There is apparently a difference in the strength of the fibre obtained from American spruce by the sulphite method as compared with imported sulphite pulps, even those made by the Mitscherlich system in Europe. Tests of raw American-made pulp and newspaper made from it, in a paper mill belonging to

Mr. Thilmann's brother, revealed the fact that from 10 to 15 per cent. more imported pulp had to be used to obtain the same results as regards strength.

The pulps imported to America are frequently mixed, so that the paper-maker is not always provided with the same make. How this occurs the importer only knows. This he keeps secret, and makes many untrue assertions regarding it. The paper-maker who has hitherto made good newspaper from 20 per cent. sulphite and 80 per cent. mechanical wood pulp, suddenly finds that his paper is much weaker, and consequently many complaints pour in upon him. He then investigates his pulps, and finds among them the most diverse qualities.

All sulphite pulp made in America and manufactured into newspaper is used for this purpose in the unbleached state.

## PATENTS.

*Transparent Printed Paper having the Appearance of Stained Glass and Means or Apparatus for its Manufacture.* W. L. Wise, London. Eng. Pat. 5418, March 29, 1889. 8d.

THE inventor claims "the manufacture in the ways and by the means described of transparent or translucent printed paper having the appearance of stained glass, using blocks and cylinders of wood or metal such as zinc, either bare or faced with caoutchouc or gutta-percha or other soft and elastic substance, and covered or not covered with a coating of gelatin." After printing, the paper is coated on both sides with varnish; and when this is dry, with another coating of gelatin or other adhesive substance.—E. J. B.

*Improvements in or relating to the Prevention of the Corrosion of Vessels, Tubes, Valves, and the like used in the Manufacture of Sulphite Cellulose.* A. J. Boulton, London. From C. H. Jung and J. P. Lindig, Freiberg, Germany. Eng. Pat. 5643, April 2, 1889, 4d.

THE vessels, thoroughly cleaned by boiling in alkali and subsequent treatment with dilute acids, are coated with a solution of acid calcium sulphite. When dry the surface is covered with a solution of silicate of soda. On to this coating a layer of a pulpy mixture of calcium sulphite and silicate of soda or potash is laid to a depth of from 1—5 centimetres. When this coating is dry and hard, water containing acid calcium sulphite is boiled in the vessel.

In case cracks should form in the coating, the boiler is connected with a dynamo and forms the cathode of an electrical circuit, while a lead plate inside the boiler forms the anode. If a crack occurs the exposed part is coated with an electrolytically formed deposit.—E. J. B.

*Improvements in the Manufacture of Artificial Ivory or Ivory Substitutes.* A. and S. de Pont, Paris, France, and H. L. and J. H. Storey, Lancaster. Eng. Pat. 9267, June 4, 1889. 6d.

THE improved artificial ivory is obtained by kneading together lime, phosphoric acid, calcium carbonate, magnesia, alumina, gelatin, and albumen, in such proportions that the resulting mixture has the same chemical composition as natural ivory. The material is subjected while hot to great pressure, and after maturing for some weeks it can be cut, turned, and polished in the ordinary way.—E. J. B.

*Improvements in Extracting Substances Dissolved in the Waste Water of Paper Manufacture.* F. C. Altkier, Wieselburg, Austria. Eng. Pat. 1514, January 28, 1890. 4d.

IN the manufacture of paper from steamed ground wood pulp, the waste water contains methyl alcohol and acetic

acid. In this process these products are recovered. Instead of using fresh water, water from previous operations is used; in this way it gradually becomes sufficiently concentrated to render the recovery profitable. To neutralise the acetic acid, lime or soda is added. The liquid is distilled to drive off the alcohol and the residue is evaporated to dryness and distilled with hydrochloric acid.—E. J. B.

*Improvements in and relating to the Construction of Digesters or Boilers for use in the Manufacture of Paper Pulp.* W. W. Keys, Bridgeport, U.S.A. Eng. Pat. 1517, January 28, 1890. *8d.*

THE boilers are cast in sections in a material known as de-oxidised bronze. It is obtained in the following manner. The surface of melted copper is covered for an hour to the depth of an inch or two with small pieces of animal horn. Tin is then added in the proportion of one to nine of copper. This bronze completely resists the action of the acid sulphite solutions used for preparing wood pulp.—E. J. B.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Iso-Cinnamic Acid, an Acid found in the Alkaloids accompanying Cocaine.* C. Liebermann. Ber. **23**, 141—156 and 512—516.

THE mixture of acids obtained by treating the alkaloids accompanying cocaine with hydrochloric acid according to the author's process (D. P. 47,602) for preparing ecgonine therefrom, contains chiefly  $\alpha$  and  $\beta$  truxillic and cinnamic acids. The residue after the separation of these acids, leaves a thick oily mass behind after extraction with ether and distilling off the latter, which does not solidify in the cold. When extracted with petroleum spirit (b.pt.  $60^{\circ}$ — $70^{\circ}$ ) a small portion of the residue dissolves and the solution deposits crystals of the new acid on standing. Special precautions were taken to obtain this acid perfectly free from ordinary cinnamic acid, advantage being taken of the greater solubility the free iso-acid in petroleum ether and of its calcium salt in water. Iso-cinnamic acid melts at  $57^{\circ}$  (ordinary cinnamic acid at  $133^{\circ}$ ), and forms characteristic monoclinic crystals quite distinct from those of either cinnamic, hydrocinnamic or atropic acid; further the non-identity of the new acid with any of the above is fully borne out by its physical and chemical characters. Analyses and a molecular weight determination by Raoult's method point to the formula  $C_9H_8O_2$ . On oxidation with potassium permanganate in alkaline solution benzaldehyde is formed. The calcium, barium, cobalt, manganese and zinc salts of the acid are soluble, the copper and mercury salts insoluble in water; the silver salt is unacted on by light, and when treated with methyl iodide yields the methylester of isocinnamic acid. Isocinnamic acid begins to boil at  $265^{\circ}$ , and is converted quantitatively into ordinary cinnamic acid, but on continued heating carbon dioxide is evolved and styrene  $C_8H_8$  formed. This conversion into cinnamic acid is also effected by treatment with sulphuric acid or with iodine in carbon bisulphide solution. With many reagents derivatives of ordinary cinnamic acid result, thus, nascent hydrogen gives ordinary hydrocinnamic acid; bromine, —dibromcinnamic acid, hydrobromic acid,—phenyl- $\beta$ -bromopropionic acid and hydrochloric acid,—phenyl- $\beta$ -chloropropionic acid. The author also found a small quantity of iso-cinnamic acid in ordinary cinnamic acid prepared from storax, but failed to detect it in cinnamic acid from benzaldehyde.

The following constitutional formula is assigned to the acid—

Ordinary cinnamic acid being—

The less stable nature of the iso-acid as compared with the normal acid agrees with the formula; this is further confirmed by its conductivity when dissolved, for electricity, which is about five times as great as that of the ordinary acid. —C. A. K.

*On a Compound of Calcium Chloride and Normal Propyl Alcohol.* C. Göttig. Ber. **23**, 181—182.

THIS compound was first obtained as a by-product when drying commercial propyl alcohol by calcium chloride.

When a portion of the propyl alcohol had been distilled off from the calcium chloride, the residue on standing deposited two bodies, the bottom one was opaque and consisted of calcium chloride, containing variable quantities of alcohol and water, the upper one was transparent, and consisted of needle-shaped crystals; it was dried between blotting paper, and on analysis gave numbers corresponding with the formula  $CaCl_2 \cdot 3 C_3H_7O$ . To determine whether this was an accidental mixture, the substance was recrystallised from pure propyl alcohol and gave the same analytical number.

The body forms short transparent needle-shaped crystals, of a slightly greater density than water. When small pieces are thrown into water they move about on the surface whilst dissolving, and are decomposed into propyl alcohol and calcium chloride; larger pieces sink to the bottom and dissolve more slowly. On exposure to the air it absorbs water, and in a desiccator, over sulphuric acid, loses alcohol.—A. L. S.

*Hydrastine.* M. Freund and A. Rosenberg. Ber. **23**, 404—415. (Compare this Journal, 1889, 1006.)

THE near relationship which exists between narcotine and hydrastine would lead to the expectation that the halogen-alkyl addition products of the two alkaloids would also show a similar behaviour. Experiments instituted some time ago with the object of preparing a compound from hydrastine, analogous to the pseudonarcine  $C_{21}H_{23}NO_6 + 3H_2O$  obtained by Roser (Annalen **247**, 167) from narcotinemethyliodide, gave such abnormal results that a more complete investigation has now been carried out.

*Hydrastinemethyliodide*,  $C_{21}H_{21}NO_6 \cdot CH_3I$ , melting at  $208^{\circ}$  is the sole product of the action of methyl iodide on hydrastine. When digested with silver chloride and water it is converted into the corresponding *methylechloride*.

*Hydrastinemethylhydroxide*,  $C_{21}H_{21}NO_6 \cdot CH_3OH + H_2O$ , is formed, together with *methylehydrastine* when this methylechloride is treated with potash in the cold. The reaction which takes place may be represented by the equations—

I.

II.

The crystals of methylhydrastine are separated by filtration, and the alkaline filtrate evaporated, whereon the hydroxide is obtained in colourless prisms. It melts at  $242^{\circ}$  and is readily soluble in hot water and dilute alcohol; it is identical with the compound (m.p.  $236^{\circ}$ — $238^{\circ}$ ) previously described (Ber. **19**, 2799), obtained by treating the methyl iodide with moist silver oxide.

*Methylhydrastine*,  $C_{22}H_{23}NO_6$  (see above), is the principal product of the action of potash on hydrastinemethylchloride. It crystallises in yellow needles, melts at  $156^\circ$  and is almost insoluble in water but readily soluble in chloroform, benzene, carbon bisulphide, ether and dilute alcohol. It dissolves in Fröhde's reagent, yielding a violet solution which quickly turns blue, and then slowly becomes green. The *hydrochloride*  $C_{22}H_{23}NO_6 \cdot HCl$  melts at about  $241^\circ$  with decomposition, and is moderately easily soluble in hot water. The *platinochloride*, *nitrate* and *sulphate* are more sparingly soluble.

*Methylhydrastinemethyliodide*,  $C_{22}H_{23}NO_6 \cdot CH_3I$ , is formed when methylhydrastine is treated with methyl iodide in cold alcoholic solution. It crystallises in yellowish needles, decomposes at  $250^\circ$ , and is more readily soluble in hot water than in alcohol; it is readily decomposed by alkalis with liberation of trimethylamine and formation of a compound of the composition  $C_{20}H_{20}O_8$ . This reaction may be represented by the equation:  $-C_{22}H_{23}NO_6 \cdot CH_3I + KOH + H_2O = KI + N(CH_3)_3 + (C_{20}H_{20}O_8)_x$ .

*Methylhydrastine*,  $C_{22}H_{27}NO_4 + H_2O$ , is obtained by warming hydrastinemethylchloride with excess of potash; on neutralising the concentrated solution with acetic acid the product separates in crystals. It is more conveniently prepared by boiling methylhydrastine with concentrated potash until an oil begins to separate, then evaporating, dissolving the oil in water and neutralising with acetic acid. The new compound then separates in crystals and can be purified by recrystallisation from water. It melts at  $150-151^\circ$ , loses its water at  $100^\circ$ , and is readily soluble in hot water and alcohol; it dissolves in mineral acids and in alkalis, but it is insoluble in sodium carbonate and dilute acetic acid. It gives the same colouration with Fröhde's reagent as methylhydrastine, and it is coloured red by ammonia and chlorine water, but it is not acted on by iodine. It is optically inactive and resembles pseudonarcotine in many respects. It is a tertiary base, combines with methyl iodide in the cold, and is reconverted into methylhydrastine by hot concentrated hydrobromic acid. The salts are colourless. The *hydrochloride*  $C_{22}H_{27}NO_4 \cdot HCl + H_2O$  melts at  $290^\circ$  and is soluble in water.

*Hydrastine-ethylhydrastine*  $C_{21}H_{21}NO_6 \cdot C_2H_5OH + 2\frac{1}{2}H_2O$  and *ethylhydrastine* were prepared from hydrastine ethyl-iodide exactly as described in the case of the corresponding methyl compounds. The hydroxide crystallises from dilute alcohol, melts at  $225^\circ$ , and is identical with the compound obtained by Wilhelm (Arch. Pharm. 1888, 341).

*Ethylhydrastine*  $C_{20}H_{25}NO_6$  melts at  $126-127^\circ$ , and forms yellow, crystalline salts with hydrochloric and with nitric acid; it combines with ethyl iodide yielding *ethylhydrastine ethylchloride*  $C_{22}H_{27}NO_6 \cdot C_2H_5I$ . This compound melts at  $241^\circ$ , and is decomposed by alkalis in the same way as the corresponding methyl derivative.

*Ethylhydrastine*,  $C_{22}H_{29}NO_3 + 2H_2O$ , obtained from ethylhydrastine as described in the case of the methyl derivative, crystallises from hot water in needles and melts at  $130^\circ$ .

The tertiary nature of hydrastine having now been established, and bearing in mind the analogy existing between narcotine and hydrastine, the constitution of the latter may be represented by the formula—

*Methylhydrastine* has probably the constitution (I.), whilst that of methylhydrastine may be represented by the formula (II.).

—F. S. K.

*The History of Hydrastine.* M. Fremd. Ber. **23**, 416—417.

A CLAIM for priority.—F. S. K.

*Taxin, the Alkaloid of the Yew Tree (Saxus Baccata).* A. Hilger and F. Brande. Ber. **23**, 464—468.

BEJARDIN, Schroff, and Lucas have pointed out the presence of a narcotic substance in the leaves, shoots, and fruit of the yew tree, whilst Marmé isolated the alkaloid in question by extracting the leaves, &c. with ether, treating the residue, after distilling off the ether, with dilute acid, and then precipitating the base by means of ammonia. The authors have adopted this method of Marmé's for the extraction of the alkaloid, to which the name of *taxin* is given. The acid extract (sulphuric acid was used) is coloured at first, but on repeating the treatment with acid and ammonia two or three times a perfectly colourless product is obtained in the form of a white amorphous powder, melting at  $82^\circ C$ . All attempts to obtain the alkaloid in a crystalline condition failed. Taxin when heated in a glass tube forms a white cloud, which condenses in oily drops on the cool parts of the tube. These drops solidify on cooling. At the same time it gives off a characteristic aromatic odour. It dissolves readily in alcohol and ether, less readily in chloroform, very slightly in water, and is insoluble in benzene. With concentrated sulphuric acid an intense purple-violet colouration results, whilst the slightly acidified aqueous solution of the base gives yellow precipitates with solutions of iodine and of bismuth iodide in potassium iodide, a pale yellow precipitate with sodium phospho-molybdate, and a white precipitate with the fixed alkalis and with ammonia, insoluble in excess. Gold chloride, platinum chloride and picric acid also produce characteristic precipitates of double salts. The alkaloid possesses a very bitter taste. Taxin forms a series of very soluble salts, of which the acetate, oxalate, tartrate, hydrochloride, and sulphate have been prepared. It is difficult to obtain them in a crystalline form, the hydrochloride being prepared as a crystalline precipitate by passing dry hydrochloric acid gas into an anhydrous ethereal solution of the base. Analyses of the free base, its hydrochloride, sulphate,

and also of its difficultly soluble double salts with the chlorides of gold and of platinum are given, which point to the empirical formula  $C_{37}H_{52}O_{10}N$  for the alkaloid. It is mon-acid. Heated with ethyl iodide in a closed tube to  $100^\circ$ , a crystalline product  $C_{37}H_{52}O_{10}N.C_2H_5I$  results, pointing to the fact that taxin is a nitrile-base.—C. A. K.

*Dextro-rotatory Cocaine.* A. Einhorn and A. Marquardt. Ber. **23**, 468—474.

THE experiments of Ladenburg and others have shown that certain atropine derivatives are capable of being converted into molecular isomers which differ in their action on polarised light and in their physical properties. Since cocaine like atropine contains two asymmetric carbon atoms, the authors have tried similar experiments with cocaine derivatives, and find that eegonine, eegonine methylester, benzoyl eegonine, cocaine, and the alkaloids that are found with cocaine in the coca leaves, are all converted, by warming with caustic potash, into a dextro-rotatory eegonine. This body differs from ordinary eegonine in its physical properties; it melts at  $254^\circ$ , ordinary eegonine at  $198^\circ$ . The rotatory power of a 4.4 per cent. solution in a 2 dem. tube is  $+1.6$ . Its hydrochloride and double salt with gold chloride both differ somewhat from the corresponding salts of ordinary eegonine. Heated with glacial acetic and hydrochloric acids, anhydro-eegonine, identical with the product derived from ordinary eegonine results. The methylester of dextro-rotatory eegonine is readily prepared, and is a crystalline body melting at  $115^\circ$ . When heated with benzoylchloride it is converted into a dextro-rotatory cocaine, the hydrochloride of which can be obtained from aqueous or alcoholic solution in beautiful crystals, melting at  $205^\circ$ . Ordinary cocaine hydrochloride melts at  $181^\circ.5$ . A 1.9 per cent. solution of this salt in dilute alcohol in a 2 dem. tube has a rotatory power of  $+1^\circ.5$ .

The physiological action of this isomer of cocaine differs from that of ordinary cocaine only inasmuch as that its local anæsthetic action takes effect and disappears more rapidly. The authors hope to be able to prepare dextro-rotatory compounds in a similar way from the other levo-rotatory cocaine derivatives, and to convert ordinary cocaine into this new isomer by an analogous reaction.—C. A. K.

*A By-product in the Commercial Synthesis of Cocaine.* C. Liebermann and F. Giesel. Ber. **23**, 508-512.

WHAT appears to be a methyl cocaine has been obtained by the authors in small quantities from the mother liquors in the synthetical method of preparation of cocaine from eegonine. The free base when separated from a salt by means of an alkaline carbonate forms an oil which solidifies on standing, and which is readily soluble in ether, alcohol, benzene, and petroleum spirit. Its salts crystallise well, the difficultly soluble nitrate  $C_{18}H_{29}NO_3.HNO_3$  being especially characteristic. The hydrochloride, sulphate, gold and platinum double chlorides are also described. Methyl cocaine is less readily decomposed by water or by hydrochloric acid than ordinary cocaine is. With acid, benzoyl-methyl eegonine hydrochloride ( $C_{17}H_{23}NO_3.HCl$ ) first results, and then methyl-eegonine,  $C_{16}H_{21}NO_3$ , which latter melts with decomposition at  $264^\circ$  and forms a characteristic hydrochloride and gold double salt. The analytical data on which the determination of the composition of this methyl cocaine rest are not sufficiently accurate to decide between the formulæ for cocaine and methyl cocaine, and the authors refer to the isomeride of cocaine described by Einhorn and Marquardt (this Journal, 1889, 135,) which agrees in some of its properties, especially as regards the melting points of its hydrochloride and gold double salt with this methyl cocaine. Further, the latter, as well as the "methyl eegonine," have a dextro-rotatory power equivalent to that of the corresponding derivatives described by Einhorn and Marquardt. On the other hand there are several differences to be noticed in the two series of compounds, so that their identity or otherwise still remains to be proved.—C. A. K.

*On Dextrococaine and its Homologues.* A. Einhorn and A. Marquardt. Ber. **23**, 979-988.

THIS body was obtained in crystals, melting at  $43-45^\circ C$ , by treating its solution with a crystal of benzoyldextro-eegonineethylester. Its gold and platinum double salts, the hydrobromide, hydriodide, nitrate and sulphate are described. Whether dextrococaine is identical with Liebermann and Giesel's methylecocaine is not yet finally decided, though the bases are very much alike; there are however still slight differences, and further researches on this point require to be made.

*Benzoyldextro-eegonine hydrochloride* is obtained by heating dextrococaine for 48 hours with water. After removing some benzoic acid with ether, the aqueous solution is concentrated, hydrochloric acid added, and the salt recrystallised from alcohol or water. It forms needles or prisms melting at  $244-245^\circ C$ . The dextro-eegonine esters are prepared by covering the hydrochloride with the particular alcohol, and passing gaseous hydrochloric acid into the mixture, until the salt is dissolved, the excess of alcohol is removed by evaporation, and from the residue the ether is liberated by potassium carbonate. All these compounds prepared hitherto, consist, with the exception of the amylester, of oils; the amylester forms yellow prisms melting at  $152^\circ C$ . If these esters be mixed with double their volume of benzoylchloride and heated in the oil bath to  $160-165^\circ$ , removing benzoic acid, and addition of potassium carbonate, new alkaloids were obtained.

*Benzoyldextro-eegonine ethylester—*

White hard prisms melting at  $57^\circ C$ ; its hydrochloride melts at  $215^\circ C$ .

*Benzoyldextro-eegonine propylester—*

The hydrochloride melts at  $220^\circ C$ . The free base is an oil.

*Benzoyldextro-eegonine isobutylester—*

The hydrochloride melts at  $201^\circ C$ . The free base is an oil.

*Benzoyldextro-eegonine amylester—*

is an oil. The hydrochloride melts at  $217^\circ C$ .—A. L.

*The Physiological action of Selenious Acid.* C. Chabrie and L. Lapieque. Compt. Rend. **110**, 152—154.

CHABRIÉ has shown (Bull. Soc. Chim. **50**, 133) that selenious acid is reduced to selenium by a glucose solution containing yeast, but not by a sterilised solution. It is now shown that (1) the proportion of selenious acid necessary to prevent fermentation of *bouillon* exposed to the ordinary microbes present in air slightly exceeds 2 per thousand; (2) that with a smaller percentage of  $SeO_2$ , fermentation takes place and selenium is deposited on the micro-organisms.

Sodium selenite (perfectly neutral) injected into the blood of dogs in the proportion of 3 per 1,000 of the total weight of the animals, was found to be fatal. The physiological phenomena induced are described in detail, and it is concluded that sodium selenite is an irritant poison. The authors failed to discover the acicular crystals which Rabateau found after similar experiments. They contrast the toxicity of selenites with the innocuity of sulphites, these being immediately after injection transformed into sulphates.

—P. J. H.

*Report on New Drugs and Fine Chemicals.* Merck's Bull. 1890 [3], 17—24.

*Borates of Alkaloids.*—Petit and Galezowsky (Les nouv. Remèdes, 1889, 143) especially recommend these for the preparation of eye washes, since boric acid, even if present

in excess, will exert no deleterious action in such application, whilst any other acid which might be combined with the alkaloids used would produce irritant effects. The following borates of mydriatic and myotic alkaloids have so far been placed on the market:—Atropine-, cocaine-, physostigmine- (eserine), morphine-, and pilocarpine-borates.

**Cetraric Acid (Cetrarin),**  $C_{14}H_{10}O_8$ , the bitter principle contained in *Cetraria islandica* (Iceland moss), forms white needles with a bitter taste and readily soluble in boiling alcohol. Physiological and therapeutic researches on cetraric acid were first made by Köhler and Müller (Pflanzenstoffe. Husemann and Hilgers, 318), and these were supplemented by the more recent investigations of A. Fortunatow (Zur Frage über die Wirkung der Bittermittel, Inaug. Dissert. St. Petersburg, 1884), which developed new and interesting facts.

Fortunatow showed that intravenous injections of cetraric acid augment the secretions of the pancreas, and still more so those of the salivary glands. Further, that doses of 2–4 centigrams per kilo. of the animal's weight (2–4 parts per 100,000) injected into the blood increase the biliary secretion by 2–4-fold its usual quantity.

Intravenously injected, cetraric acid has no effect on the gastric digestion, whereas, administered by the mouth, it exerts a disturbing influence thereon. Professor Kobert, of Dorpat University, promises further experimental results.

**Codeine Phosphate**, soluble in 4 parts of water, is used hypodermically in cases of insomnia, insane excitation, and hallucinations. It acts less energetically than hyoscyne, and is useful when the use of the latter is accompanied by hallucinations.

Codeine phosphate is also useful for the treatment of morbinism, as demonstrated by Schmidt (Wiener Med. Presse, 1889, 43). A 10 per cent. solution was found best for internal use.

**Di-iodosalicylic Acid,**  $C_6H_3I_2(OH).CO_2H$ .—This is a white powder, consisting of microscopic needles, but little soluble in cold water, rather more soluble in hot water, and readily soluble in alcohol and ether. It acts as an analgetic and antithermic at the same time, retarding the action of the heart. It is excellent as an antiseptic.

Di-iodosalicylic acid was especially valuable in certain cases where salicylic acid and its salts had remained void of effect.

**Lobeline, Alkaloid and Sulphates.**—The alkaloid is obtained from the leaf or seeds of the plant "*Lobelia inflata*," and it takes the form of a yellow syrupy liquid which darkens on keeping. The sulphate is best suited for medicinal use. Two sulphates are obtainable, viz.:—

**Lobeline Sulphate** from the Lobelia seeds. Yellowish, crumb like, little granules, extremely hygroscopic, and hence difficult of exhibition in powder form.

**Lobeline Sulphate** from the leaves.—Yellowish white powder, less hygroscopic than the sulphate from the seeds. The physiological actions of these sulphates have not been observed to differ from each other.

Dreser states (Archiv für exp. Path. and Pharm. 1889, 237) that *Lobeline* is the only medicinally active principle peculiar to the leaves and seeds of *Lobelia inflata*. It kills warm-blooded animals by paralyzing the respiration. Silva Nunez has recently most warmly recommended the use of Lobeline in the treatment of bronchitical dyspnea and spasmodical asthma. (Brit. Med. J. 1889, 1051.) This alkaloid is immensely superior to the old Galenic preparation of lobelia.

**Pseudo-Ephedrine,**  $C_{10}H_{15}ON$ .—The pure alkaloid is useful as a mydriatic. It is a crystalline substance and has a faint but agreeable odour. It is easily soluble in alcohol, with difficulty in cold water, somewhat more readily in hot water. Melting point (uncorrected) about  $114^{\circ}$ – $115^{\circ}$  C. The constitution is probably—

The physiological action on the eye has been investigated by A. de Vries (Ann. Oculist du Warlomont, 1889, iii.

and iv., 183). The practical advantages in its use over other mydriatics are summed up thus:—"It occasions neither inflammation nor disturbances of refraction; it does not modify the intra-ocular pressure, and it can be employed for a long time without causing any injury." (This Journal, 1889, 724; also *ibid.*, 304).

**Theobromine and Sodium Salicylate ("Diuretin").**—This is a white crystalline powder, but slightly soluble in cold water. It is soluble in hot water and in warm dilute alcohol, but insoluble in ether and in chloroform. The salt has been clinically investigated by Ch. Gram (Therapeut. Monatsh. 1890, 10), who states that it is much more easily absorbed than simple theobromine. Its action is strongly diuretic, whilst it is devoid of any toxic properties and free from the peculiar excitant influence on the central nervous system possessed by Caffeine. It was first prepared by Merck at the instance of Dr. Riegel of Giesseur.

Merck's Bull. 1890 [4], 25–32.

**Abrin** is obtained from the seeds of *Abrus precatorius* ("Indian liquorice" or "*Jequirity*"). It is a brownish-yellow powder soluble in water, and consists of an exceedingly poisonous albuminoid or proteid substance belonging to the class of unorganised ferments. In these respects it much resembles "Ricin" (page 545). The lethal dose, according to Kobert, is only 0.00001 gram per kilo. of the animal's weight, i.e. 1 to 100,000,000. Hence the enormous toxicity of the substance calls for extreme caution in its preservation, handling, and exhibition. Of high therapeutic interest is the fact that Kobert has succeeded in inducing the well known "*Jequirity ophthalmia*" both by "*Abrin*" and "*Ricin*." (Brit. Med. J. 1889, 1053).

**Ethylbromide,  $C_2H_5Br$ .**—This is becoming more and more recognised as superior, especially in small operations, to chloroform, and Gilles of Cologne, after employing it in over 450 painful dental operations says:—"Ethylbromide, when chemically pure, is a most excellent general anæsthetic, because it acts promptly and certainly, and when employed with due care, without danger. Its advantages over chloroform, nitrous oxide, cocaine, and other anæsthetics in general use, are so vast that with the exception of some rare and very complicated cases, it must soon come to be recognised as the sole standard anæsthetic in dental surgery." Both C. E. Diehl (Les nouveaux Remèdes, 1889, 361), and O. Eschricht (Deutsch. med. Wochenschr. 1889, 15, 31), testify in similar terms to the superiority of ethylbromide. Careful experiments instituted on the occasion of the Sixty-second Annual Meeting of German Naturalists and Physicians at Heidelberg, brought forth the unanimous verdict from the meeting that ethylbromide is *not a heart poison*. The pure substance is a colourless, limpid, very mobile and not readily inflammable liquid, scarcely soluble in water, though miscible in all proportions with alcohol, ether, chloroform, or fatty and ethereal oils. Sp. gr. at  $15^{\circ}$ , 1.45. Boiling point,  $38^{\circ}$ – $39^{\circ}$  C. Shaken with an equal volume of distilled water, pure ethylbromide must not impart to the latter any acid reaction (Absence of  $HBr$ ). Mixed with an equal volume of pure conc. sulphuric acid, no colouration must arise in 24 hours. (Absence of ethylene, amyl, or sulphur compounds.) A few drops of ethylbromide thrown into a stratum of KI solution about 3 cm. deep, must not, in settling, show any violet colour. (Absence of free  $Br$ .) The drug must be kept in a cool, dark place, and also in small dark coloured, entirely filled and well stoppered bottles, since decomposition ensues otherwise under the influences of air and light.

**Iron Succinate.**—This is an amorphous, reddish-brown powder, insoluble in water and alcohol.

In conjunction with chloroform, it is very efficacious in biliary calculi (Buckler, Therapeutic notes in the Deutsch. med. Zeit. 1889, 79).

**Lanolin (Anhydrous).**—Consists essentially of the esters of various fat acids with cholesterol. Lanolin is quite indifferent to solutions of salts of which it is capable of absorbing and retaining almost double its own weight. At ordinary temperatures it is not attacked either by acids or aqueous alkaline solutions and its absorbability by the skin has been already referred to. (This Journal, 1886, 578—

580; 1890, 356--358.) To this property it owes its extensive use as an ointment-basis. Anhydrous lanolin has a melting point of about  $45^{\circ}\text{C}$ ., it is insoluble in ether, and it yields homogeneous mixtures with aqueous and alcoholic liquids as well as with fatty and ethereal oils. Anhydrous lanolin does not become rancid, and will keep for any length of time. Hence it is the only really eligible ointment-base for hot climates. It gives Liebermann's cholesterol reaction, and also that known as Salkowsky and Vulpinus's chloroform and sulphuric acid reaction. The full series of reactions to be fulfilled by pure lanolin have been enumerated by Bernhard Fischer (*Die neueren Arzneimittel*, 1888, 63). The use of anhydrous lanolin is especially indicated when solutions of salts or extracts in large proportions, are to be incorporated with a fatty substance. When large proportions of powdered medicaments are to be mixed directly with anhydrous lanolin without the intervention of water, it is advisable to mix 30 per cent. of olive oil, or, better still, vaselin.

**Ricin.**—This is an albuminoid or proteid substance. It is obtained from the seeds of the castor-oil plant (*Ricinus communis*), and is one of the unorganised ferments similar to *Abrin* (page ), and like the latter has enormous toxic properties and produces "*Jequivity ophthalmia*." Ricin is a white amorphous powder, most readily soluble in a 10 per cent. solution of sodium chloride. Pure ricin in aqueous solution has a neutral reaction. The high toxic powers of ricin hold no relation to the familiar effects of castor oil. Intravenously administered ricin gives lethal effects in doses even below 0.00003 grm. per kilo. of the animal's weight (3 to 100,000,000). The lethal dose by mouth, for a human being (132 lb.) would be about 0.18 grm. ( $2\frac{3}{4}$  grains). Solutions of ricin on being boiled entirely lose their active properties, whilst dry ricin sustains a temperature of  $100^{\circ}\text{C}$ . intact. Robert and Stillmark, who have investigated its physiological action (*Arbeiten des Pharm. Inst. zu Dorpat*, 1889, 3, 59), also found other and similar poisonous albuminoids in the seeds of many species of *Ricinus*, in those of *Croton Tiglium* (croton-oil plant), Barbadoes nuts (seeds of *Jatropha Curcas*), and *Jequivity*.

**Synthetic Carbolic Acid.** A. Schneider. Pharm. C. H. N. F., 1890, 68.

In order to determine whether synthetic carbolic acid turns red under the same conditions as coal-tar carbolic acid, the author has investigated the action of various metals, wood, cork, &c., and finds that the colouration is due to the presence of traces of copper, which are probably derived from the vessels in which the substance is distilled.—J. B. C.

**The Action of Saccharin.** F. Jessen. Arch. f. Hygiene, 1890, 64.

The easily soluble saccharin is without action on the malting of starch by means of ptyalin, and has a slightly retarding action in the peptonising of albumen. The presence of large quantities of saccharin has no effect on the digestion of milk or on the digestive organs themselves. By the daily use of 1—2 grm. over a period of three months the author has observed no injurious action in several cases, and the author has himself taken 5 grms. per diem without any unpleasant effects. In 27 hours the last trace of saccharin is discharged in the urine. Pure saccharin has a slightly retarding action upon bacterial ferments; but none in the case of pathogenic ferments.

—J. B. C.

**The Action of Light on Phosphorus and on some of the Properties of "Amorphous" Phosphorus.** A. Pedler. Proc. Chem. Soc. (82), 1890, 66—67.

As part of an extensive series of experiments on the action of strong light on substances, the author has studied its effect on phosphorus, and has thereby been led also to

examine and compare the several forms of allotropic phosphorus, viz., that produced by the action of light only, that produced at moderate temperatures, the commercial form, and also rhombohedral or metallic phosphorus prepared by dissolving phosphorus in lead at high temperatures.

The conclusion is arrived at that the term "amorphous phosphorus" is a distinct misnomer, and that, so far from commercial "amorphous" phosphorus constituting a separate allotropic modification of the element, it is in reality the same substance as the form called rhombohedral or metallic phosphorus, the very slight differences in character noticed between the substances in question being explained by the difference in the state of division and the slight variations conditioned by their mode of formation. Whether the term amorphous phosphorus can be truly applied to the forms made by the action of light is open to grave doubt; even in this case there appears to be distinct evidence of crystalline form, although in some instances a form which appeared to be amorphous was obtained. It is suggested that it would be better to altogether discard the use of the term *amorphous phosphorus*.

The author finds that when phosphorus is exposed to light in contact with liquids containing oxygen, such as alcohol, it tends to enter into action with them. He arrives at the conclusion that neither *in vacuo* nor at ordinary pressures is there any change whatever of red into ordinary phosphorus at  $260^{\circ}$  as ordinarily stated; and that, practically, no change occurs up to temperatures of nearly  $358^{\circ}$ , above which, *in vacuo*, change takes place, but exceedingly slowly, even up to  $445^{\circ}$ . He also describes experiments which tend to show that red phosphorus is not permanent in air, as commonly supposed.

#### PATENTS.

**A Method of producing a Substitute for Musk.** A. Baur, Gispersleben, Germany. Eng. Pat. 4963, March 21, 1889. 4d.

TOLUENE is heated with the chloride, bromide, or iodide of butyl in presence of aluminium chloride or bromide, and the resulting hydrocarbon  $\text{C}_{11}\text{H}_{16}$  distilled off from the products of the reaction by means of steam. The distillate is fractionated, and the product of boiling point  $170^{\circ}$ — $200^{\circ}$  nitrated with a mixture of fuming nitric and sulphuric acids. It is this nitro-product, which is separated by precipitation with water and recrystallisation from alcohol, that possesses a strong smell of musk.—C. A. K.

**Improvements in the Manufacture of Ethyl Mercaptan.** O. J. Steinhart, London. Eng. Pat. 6494, April 16, 1889. 4d.

THE object of the invention is to prepare pure ethyl mercaptan from ordinary methylated spirits. One part by weight of ordinary methylated spirits is mixed with two parts of concentrated sulphuric acid, and the mixture gently heated over the water-bath for an hour. The solution is then poured into cold water, neutralised with an alkaline carbonate and evaporated, whereby the greater part of the alkaline sulphate as well as resinous matters, due to impurities in the spirit, are removed. The impure sulphovinate solution is then heated with a strong aqueous solution of potassium sulphhydrate and the product of the reaction distilled from the water-bath, when the bulk of the methyl mercaptan escapes owing to its low boiling point, whilst the ethyl mercaptan is condensed and collected. The product is further purified by careful fractional distillation.

The patentee also converts the methylated spirits into crude ethyl chloride, and treats this product with an alcoholic solution of potassium sulph-hydrate, the resulting mercaptan being purified as described above.—C. A. K.

*Process of Manufacturing Coumarone.* A. A. Vale, London. From The Chemische Fabriken Actien Gesellschaft, Hamburg, Germany. Eng. Pat. 1422, January 27, 1890. 4d.

NAPHTHA, or the light tar oils freed from pyridine bases and phenols are well fractionated so as to separate the portion boiling between  $165^{\circ}$ — $175^{\circ}$ , and the contained coumarone precipitated as the picrate,  $C_8H_6O.C_6H_5(NO_2)_3.OH$ , by the addition of the requisite amount of picric acid. The crystals are dried and decomposed by hot water or dilute alkali, and the liberated coumarone removed by distillation with steam, the picric acid employed being recovered from the residue. (See this Journal, 1890, 275.)—C. A. K.

## XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

*Intensification of Negatives.* C. Jones. Phot. J. 14, 40—45.

THE author proved by direct experiment that when mercuric chloride acts on the metallic silver composing the image on an ordinary gelatin plate, silver chloride and mercurous chloride are formed in strict accordance with the equation  $Ag + HgCl_2 = AgCl + HgCl$ . The properties of the product lead to the conclusion that it is a definite double chloride and not merely a mixture. When sodium sulphite comes in contact with silver chloride the latter is dissolved and probably silver sulphite is formed. When mercurous chloride is treated with sodium sulphite half the mercury is reduced to the metallic state and half dissolves in the form of mercuric sodium sulphite. The sulphite is not oxidised and does not act as a reducing agent. When mercurous silver chloride formed in accordance with the first equation is treated with sodium sulphite, all the chlorine, three-fourths of the mercury, and half the silver are dissolved, the remaining mercury and silver being reduced and forming the image. The reaction is represented by the equation  $4 HgAgCl_2 = 3 HgCl_2 + 2 AgCl + Ag_2Hg$ , the two chlorides being dissolved by the sulphite. Whether this reaction results in an increase in the opacity of the image depends mainly on the physical character of the film and of the original deposit. The author is unable to confirm the statements that the opacity of the image can be indefinitely increased by repeating the process several times or can be reduced by treating with sodium thiosulphate.

Ferrous oxalate reduces mercurous chloride and silver chloride separately to the metallic state, and it likewise reduces mercurous silver chloride completely. A method of intensification which enables the operator to control the opacity of the resulting image is to immerse the negative in a saturated solution of mercuric chloride mixed with 0.2 to 0.3 per cent. by volume of strong hydrochloric acid. When all the silver has been converted into silver chloride the plate is well washed and treated with a ferrous oxalate developer made by mixing 6 parts of a saturated solution of potassium oxalate with 1 part of a saturated solution of ferrous sulphate. All the mercuric chloride must be washed out of the film before applying the ferrous oxalate, and the latter, which acts somewhat slowly, must also be thoroughly washed away. If the resulting image be again treated with mercuric chloride, followed by ferrous oxalate, a further increase in opacity will result. A third treatment gives still more opacity, and thus the image can be gradually built up to any required density.—C. H. B.

*Properties of the Acid Fixing-Bath.* A. Lainer. Phot. Corr. 1890, 16—18. (Compare this Journal, 1889, 637; 1890, 102.)

A STRONG acid fixing-bath, made by mixing equal parts of sodium thiosulphate solution and sodium hydrogen sulphite solution, gradually removes fog from gelatin negatives without any sensible loss of detail and without injuring the film. The reducing action is greatly accelerated by addition of a very small quantity of potassium ferrieyanide. The acid fixing-bath also reduces the intensity of prints on albumen paper, gelatino-chloride paper, &c., but at the same time alters their colour; it is also superior to sodium thiosulphate alone as an accelerator in conjunction with the ferrous oxalate developer, as Belitski has already stated. It will also remove brown stains resulting from mercurial intensification or from contact of the moist film with paper containing silver nitrate. Silver sulphide is precipitated much more readily from waste acid fixing-bath than from the ordinary neutral bath.—C. H. B.

*Silver in the Fixing Bath used for Gelatin Negatives.* A. Lainer. Phot. Corr. 1890, 70.

AN old fixing bath was found to contain 184 grms. of silver per hectolitre. In order to obtain this quantity of silver about 1,230 plates of cabinet size must have been fixed.

—C. H. B.

*Formaldehyde Sodium Bisulphite as an Addition to Gelatino-Bromide Emulsion and to Developers.* J. M. Eder. Phot. Corr. 1890, 105—107.

ADDITION of formaldehyde-sodium bisulphite to an emulsion does not materially accelerate the process of ripening, but tends to produce fog, and gives no appreciable increase in sensitiveness. When added to the ordinary pyrogallol developer its effect is uncertain, although in some cases a greater amount of detail is obtained in the resulting image. Immersion of an exposed plate in a solution of 1 part of the salt in 1,000 to 2,000 parts of water previous to development with ferrous oxalate reduced the time required for development and gave an image with a greater amount of detail, in this respect behaving like a very dilute solution of sodium thiosulphate. In order to avoid fog, however, it is desirable to wash the plate after removing it from the preliminary bath and before placing it in the ferrous oxalate solution.

—C. H. B.

*Magnesium Chloride as a Fixing Agent.* Liesegang. Phot. Arch. 1890, 76.

MAGNESIUM chloride dissolves silver chloride from paper prints as completely as sodium thiosulphate does. Fixing proceeds somewhat rapidly, the colour of the image is much less affected than when thiosulphate is used, and the excess of the fixing agent is readily washed out of the paper.

—C. H. B.

## PATENTS.

*Improvements in the Production of Developers for Photographic Use.* H. W. Jones, Coventry. Eng. Pat. 8085, May 15, 1889. 4d.

AN alkaline sulphite, preferably crystallised sodium sulphite, is heated until all water of crystallisation is expelled, when it is ground with quinol (hydroquinone) preferably in equal proportion, sodium bromide being added in quantity amounting to one-tenth of the whole mixture. The powder is moistened with dilute sulphurous acid, partially dried, forced through a sieve with 40 meshes to the inch, dried at a gentle heat, and the granular product compressed into discs, tablets, or pellets by means of a powerful press.

—C. H. B.

*Improvements in Apparatus for the Manufacture of Photographic Films.* A. J. Boulton, London. From G. Eastman, Rochester, U.S.A. Eng. Pat. 19,896, December 10, 1889. 8d.

AN apparatus for the manufacture of flexible transparent films from a solution of nitrocellulose and camphor in volatile solvents. It consists of a long bed-plate of polished plate glass or any other suitable material having a polished or dead surface. Over this travels, in a longitudinal direction, the spreading apparatus, which consists of a hopper holding the solution and a transverse spreading blade made in sections and fitted with automatic adjusting mechanism which compensates for any deviation of the bed-plate from a true level. Over the bed-plate slides a light cover which protects the film from dust during evaporation and also enables part of the solvent to be recovered, the vapours being drawn off from under the cover by means of an exhaust fan placed at one end. The machine is also provided with an apparatus for cutting the film into narrower strips and reeling the latter off on spools. When the film is to be used as a support for gelatin-bromide emulsion, the film is coated whilst still on the bed-plate, to which it adheres somewhat firmly. After the emulsion has set and dried the coated film is cut and reeled off.—C. H. B.

## XXII.—EXPLOSIVES, MATCHES, Etc.

### PATENTS.

*A Machine for the Continuous Manufacture and Boxing of Matches.* L. Cobbaert, Grammont, Belgium. Eng. Pat. 6595, April 17, 1889. 1s. 7d.

"THIS invention has for its object the construction of a machine by means of which the manufacture of matches is made to constitute a single continuous operation, that is to say, all the operations of this manufacture, such as the placing in presses frames of the stems of the matches, the coating of the same with paraffin, the dipping thereof into the chemical igniting compound, the drying, removing from the frames, and packing into boxes, which up to the present have been carried out by hand by means of separate apparatus, are all effected by means of one and the same machine." In order to understand this long and complex specification it is necessary to consult the numerous drawings which accompany it, and which are fully described in the text.—W. M.

*Improvements in Solidified Pyrotechnic Powders, and in the Method of Converting the same into Solid Form for Convenience in Transportation, Storage, and Combustion.* P. Jensen, London. From H. G. Underwood, Milwaukee, U.S.A. Eng. Pat. 1884, February 4, 1890. 4d.

THE object of this invention is to convert pyrotechnic powders, such as "red fire," into the solid form, and this is attained by "adding a small quantity of alcohol to the powdered ingredients, and mixing the whole thoroughly together in a water bath at a temperature of 200° F. until the mass is in a soft pasty condition, and then, while still warm, pressing the mass into moulds previously coated with vaseline or other analogous substance, and leaving it there until cool and hardened."—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

*Research on the Action of Metals upon Sulphuric Acid.* A. Ditte. Ann. Chim. Phys. 1890, 19, 68.

THE author divides the metals which are attacked by sulphuric acid into two groups.

First, those which are acted on only with warm and concentrated acid. There is a regular production of sulphurous acid and no secondary reaction. In this group are silver, mercury, copper, lead, and bismuth.

The second group consists of the more easily attacked metals which are affected by acid of any strength, more or less energetically. The main product of the reaction is hydrogen, which is produced in the cold, and seldom ceases on heating. Sulphurous acid is only formed when warm concentrated acid is used, the temperature at which it is produced varying with the metal employed. The quantity increases with the temperature. The amount of hydrogen varies inversely, and at a high temperature it ceases entirely, and only pure sulphurous acid is formed. The production of the latter decreases on diluting, and a point is reached at which it ceases, and hydrogen is alone produced.

By regulating the concentration of the acid and the temperature a known mixture of the gases can be obtained.

This reaction does not hold good with certain metals, such as magnesium, which, by acting on sulphurous acid, produce hydrogen. Here the secondary reaction assists the chief one by increasing the amount of hydrogen, and the gas contains no foreign elements. In other cases, when by the action of sulphurous acid a sulphide is formed, the main reaction is interfered with. Sulphuretted hydrogen is produced, and reacts with the sulphurous acid; both are decomposed and sulphur is deposited. If the metals and acid be brought together in such a way as to prevent the formation of sulphurous acid, then no sulphuretted hydrogen will be produced, and pure hydrogen will be obtained. To this second group belong:—Magnesium, manganese, nickel, cobalt, iron, zinc, cadmium, aluminium, tin, and thallium, and probably also the alkaline metals. (See page 549.)

—D. A. S.

*The "Gasobrometer," an Apparatus for dispensing with Reduction Calculations in Measuring Gas Volumes.* G. Lunge. Zeits. f. angew. Chem. 1890, 139—144.

IN technical gas analysis a considerable amount of time is taken up by calculations for reducing gas volumes to standard temperature and pressure. In pure gas analysis the inconvenience is not so great; for technical purposes the initial and end temperature and pressure may be taken as the same, owing to the short duration of the experiment, and for more accurate purposes "compensators" have been devised. Where, however, the gas to be measured is evolved from a weighed quantity of a liquid or solid (so that volume and weight have finally to be connected) the matter is different, and readings of thermometer and barometer have to be made, and then the necessary calculations are to be gone through. Tables of reduction have certainly been compiled for reduction of gases at various temperatures and pressures (Dingl. Polyt. J. 231, 522), but still readings of thermometer and barometer have to be made, and part of the time only is saved. To further reduce the time occupied and to render the technical chemist in this department to a great extent independent of temperature and atmospheric pressure the present apparatus has been constructed.

By means of a T-tube, D (Fig. 1), and thick-walled rubber tubing, are connected the three tubes A, B, C. A is for measuring the gas; it may be any form of nitrometer, a Bunte's burette or other convenient burette. B is the "reduction tube," which has at its upper end a spherical or cylindrical bulb. The volume to the first mark is 100 cc., the remaining narrow portion of the tube being calibrated up to 130—140 cc. in divisions representing  $\frac{1}{100}$  cc. This "reduction tube" is set once for all at the beginning of work by observing thermometer and barometer, calculating the volume which 100 cc. of perfectly dry air, measured at 0° C. and 760 mm., would occupy under the existing

conditions. This quantity of air is then introduced, and the tube closed by means of the stop-cock shown, or by fusing up the inlet (having in place of the inlet tube shown in the Figure a tube of capillary bore). If it be necessary to measure the gas moist a drop of water is introduced into this tube, and of course in the calculation necessary the barometric pressure must be reduced by the vapour tension of water; if the gases are to be measured perfectly dry (as, for instance, when using the nitrometer with sulphuric acid), a drop of sulphuric acid takes the place of the water.

C is the pressure or levelling tube.

Fig. 1.

If necessary for the purpose of regulating the temperature A and B may be surrounded with water-jackets. A, B, and C are supported by spring clamps. It is easily seen that when by raising C the level of the mercury in B has been forced up to the mark, 100, exactly the amount of pressure is exerted by C as will compress the gas in B to its volume under standard conditions.

In taking a reading A and B must be levelled and the mercury level in B must have been brought up to 100. The volume shown on A is then the volume reduced to standard temperature and pressure. In cases where the gas is generated in A itself, or where the gas is transferred to A, this is all that need be done. If, however, the gas is generated in a side apparatus, as shown in Fig. 1, A and C must first be levelled and the stop-cock of A then closed so that the gas in A is collected at atmospheric pressure. After this reduction may be effected as already explained.

In nitrogen determinations by Dumas' method, A contains caustic potash as well as mercury; this is compensated by having on the reduction tube, B, a mark at a distance below

the 100 mark equal to one-tenth of the height of the caustic potash column (sp. gr. of the caustic potash equals one-tenth sp. gr. of mercury); when taking a reading the mercury in B must be at 100, and that in A must be on a level with this new lower mark of B. Similar allowance may be made in nitrometric determinations, but the ease is here more difficult, owing to the variations in the quality and specific gravity of the sulphuric acid used. It is better in such cases to liberate the gas in a separate vessel and transfer subsequently to the burette for reduction and measurement. Fig. 2 shows a convenient form of apparatus. Of course the working part E, F need not be graduated. Before beginning the operation the mercury is made to fill E with the side tube *a*, which side tube is then capped with a caoutchouc stopper to prevent escape of the mercury during subsequent shaking. A, with its side tube *e*, is also completely filled with mercury. The substance under examination, and subsequently the acid, are added through C as usual. To transfer the gas from E to A, the cap *b* is removed and *a* is fitted to *e* by means of the rubber connection *d*. F is then raised and C lowered, the taps are carefully opened, and transference effected until the acid in E just fills *e*.

Fig. 2.

A further saving of time may be effected in works, where the instrument is to be used for always one and the same object, by marking on the gas-burette or nitrometer the weight in milligrams corresponding to certain volumes; this may be done either instead of or alongside the cc. divisions; or by using a fixed quantity of substance, percentages may be marked off directly. For nitrogen determinations by Dumas' method 1 cc. of nitrogen under normal conditions weighs 1.254 mgrm. In the case of azotometric determinations of ammoniacal nitrogen (by

sodium hypobromite) the graduations may be made to represent ammonia. Correction must be made in graduating, however, for the incompleteness of the reaction. Tables giving the corrections have been introduced, but the author has shown (Chem. Ind. 1885, 165) that these may

be dispensed with, and that it is sufficient to make a correction of 2·5 per cent. For urea, however, the correction is 9 per cent.

The following table shows substances for which gasometric methods are used:—

Substance.	Basis to which Percentages are Calculated.	Method Employed.	Gas Evolved.	1 cc. of Gas = n.gram. of Basis. (Col. II.)
Organic substances .....	Nitrogen	Dumas'	N	1·254
Ammonia salts .....	Do.	Hypobromite	N	1·285*

\* The corrections above referred to have here already been made.

—T. L. B.

#### Action of Sulphuric Acid on Aluminium. A. Ditte.

Compt. Rend. **110**, 573—576.

As the heat of formation of aluminium hydrate is 195·8 calories, aluminium should decompose dilute sulphuric acid, and even water, at the ordinary temperature.

The author finds that when a plate of aluminium is immersed in dilute sulphuric acid (2·5 in 100 of water) there appears to be no action; but this is due to the fact that an immediate action does take place, but is at once checked by the smooth surface of the metal becoming covered with a continuous layer of hydrogen, which prevents further contact of the acid and metal. In the course of days bubbles of hydrogen detach themselves from the metal, the surface of which thus becomes roughened, giving points from which bubbles can detach themselves with increasing rapidity till all the metal dissolves; in a vacuum the action is more rapid as the hydrogen detaches itself more quickly. The behaviour of aluminium is thus exactly similar to that of amalgamated zinc.

The presence of a trace of the chloride of any metal which can be easily reduced by the aluminium, and is insoluble in dilute sulphuric acid, will hasten the dissolution of the aluminium in the acid by forming a deposit on its surface, thus breaking the continuity of the layer of hydrogen.

The behaviour of aluminium in a solution of aluminium sulphate is exactly similar to its behaviour in dilute acid, a basic aluminium sulphate being formed in this case; the action is accelerated by removing the pressure on the surface of the liquid, or by adding an easily reducible chloride.

It is for the same reason that aluminium does not appear to reduce copper sulphate in dilute sulphuric acid; the presence of a trace of reducible chloride immediately brings about the reduction by breaking the continuity of the layer of hydrogen; time produces the same result. (See page 547.)—A. G. B.

On the State of Chemical Equilibrium assumed by a Gaseous Solution originally Homogeneous, of which One Part is kept at a higher Temperature than the Rest. P. van Berchem. Compt. Rend. **110**, 82—84.

A CONTINUATION of the researches of Ludwig (Wiener Ber. 1856, **20**, 339) and Soret (Archiv. des Sciences Phys. et Nat. 1879, **2**, 48, and 1880, **4**, 209; and Compt. Rend. **91**, 289) on salt solutions. The author has studied solutions of hydrochloric acid and ammonia contained in tubes, of which one part was kept at a temperature of 50°, the other at 14°, for intervals varying from 14 to 42 days. He finds that, as with the salt solutions examined by Soret, concentration of the body dissolved takes place in the colder portion of the solution, the difference of composition varying from about  $\frac{1}{3}$  to 3 per cent. for hydrochloric acid solutions, from ·2 to 2 per cent. for ammonia solutions. Between these limits the results obtained were very inconstant.—P. J. H.

#### The action of Copper Salts on Metallic Cyanides.

R. Varet. Compt. Rend. **110**, 147—149.

WHEN cupric halogen salts are heated in solution with mercuric cyanide, they are reduced and cyanogen is evolved, and a series of double salts—

is obtained, varying with the relative proportions of mercury and copper salts present. When the copper salt is in large excess, cuprous cyanide only is formed.

The author concludes from results in this and former papers that—

- (1) the halogen salts of copper act on all cyanides;
- (2) that the oxysalts of copper act on all cyanides but those of mercury and silver.

Hence these two last salts seem to have a peculiar constitution, and to possess, as Berthelot suggests, the formulae

$\text{Ag}_2(\text{CN})_2$  and  $\text{Hg}(\text{CN})_2$ . The author considers that the cyanogen radicles are linked together in these salts and are independent in all other cyanides (including that of zinc, which has been regarded by some authors as anomalous).

—P. J. II.

*On the Strength of Reagents.* R. Blochmann.

Ber. 23, 31—35.

THE author suggests that in order to introduce some uniformity into the strength of laboratory reagents, the solutions should have a relation to the molecular weight of the substance dissolved, and has drawn up tables giving a convenient strength whilst keeping to the principle of equivalent weights. The following series are made up so as to be of twice the normal strength:—Hydrochloric acid, nitric acid, sulphuric acid, acetic acid, oxalic acid, tartaric acid, caustic potash and soda, and ammonia, ammonium sulphide, chloride and carbonate, sodium carbonate, and acetate. The following are recommended to be of normal strength:—Barium, calcium and ferric chloride, potassium, magnesium, and copper sulphate, sodium phosphate, lead acetate, potassium chromate, and potassium ferrocyanide. Half-normal solutions are to be made with platonic and mercuric chloride, silver and barium nitrate. Reagents used for oxidation and reduction are to be normal, i.e., equivalent to 8 grms. of oxygen in the litre. Such substances which do not readily dissolve in water are to be used in saturated solutions.—J. B. C.

*Preparation of Platinum Black.* O. Loew. Ber. 23,

289—290.

THE catalytic action of platinum black differs considerably with the method employed for preparing the metal in this peculiar form, the product obtained by decomposing a hot solution of platonic sulphate with alcohol exhibiting this property in a greater degree than that prepared by boiling a solution of platonic chloride with sodium carbonate and sugar, or by precipitating the metal with zinc and hydrochloric acid. The author had occasion to require a very powerful catalytic agent, and after making a number of experiments succeeded in obtaining a suitable product by proceeding in the following manner:—50 grms. of platonic chloride in 50 to 60 cc. of water are mixed with 70 cc. of 40 to 45 per cent. formaldehyde, and treated gradually and with constant cooling with 50 grms. of caustic soda in 50 cc. of water. After standing for 12 hours the mixture is filtered and the precipitate washed. The filtrate, which at first has a yellow colour, assumes a black colour as soon as the greater portion of the salts (sodium chloride and sodium formate) has been removed. This is due to the fact that part of the precipitate dissolves in water at this stage; if, however, the black mass is allowed to drain on the filter it rapidly undergoes oxidation and becomes insoluble, after which the washing can be completed without further loss. The precipitate is then pressed and dried over sulphuric acid.—D. B.

*The Precipitation of Tin from Acid Solutions by means of Metallic Iron.* B. Schultze. Ber. 23, 974—976.

THE precipitation of tin by iron occurs in neutral solutions when the tin is in the form of stannous salt. When a solution of tin is in contact with a mixture of iron rust, metallic tin, and metallic iron, any free acid present is neutralised, forming ferrous sulphate and stannic sulphate, the latter again taking up tin and passing to the condition of stannous sulphate.

I.

II.

So long as there is iron oxide present the stannous salt is oxidised to stannic salt. When the acid is taken up no further oxidation occurs. Though the precipitation of tin in this manner is a very slow process, the whole of the metal is precipitated.—J. B. C.

*Analysis of Pyrolusite by means of Hydrogen Peroxide.* A. Baumann. Zeits. f. angew. Chem. 1890, 72—79.

IF powdered pyrolusite and a neutral or alkaline solution of hydrogen peroxide be brought together oxygen is given off until the whole of the hydrogen peroxide is decomposed. The manganese dioxide remains unchanged, and the action is therefore "catalytic." If a strongly acid solution of hydrogen peroxide be used, then both manganese dioxide and hydrogen peroxide give up oxygen, and the reaction is quantitatively represented by the equation—

This reaction may be used for examining samples of pyrolusite in three different ways, viz., (a) gravimetrically, (b) volumetrically, and (c) gasometrically.

(a.) *The gravimetric method* may be quite easily carried out in any approved carbonic acid apparatus consisting of feed bulb for the hydrogen peroxide, generating flask, and drying tube. The weighed sample is introduced into the flask together with 30 cc. of sulphuric acid (1 of sulphuric acid to 3 of water), a sufficient quantity of hydrogen peroxide introduced into the feed bulb, and the whole apparatus then weighed. The hydrogen peroxide is next allowed to run slowly into the flask, the whole apparatus being gently shaken. When the reaction is at an end and after the whole of the evolved oxygen has been displaced by air, the apparatus is again weighed. Difference in weight is due to escape of oxygen, as shown by the equation above. It is to be noted that the manganese ore must be powdered extremely fine. According to the equation, 100 parts of oxygen correspond to 271.68 parts of manganese dioxide, hence if 2.7168 grms. of the manganese dioxide be weighed out, the number of mgrms. of loss shown give the percentage of manganese dioxide in tenths. Hence at least 2 to 3 grms. of ore are required. Where the ore contains only 30—60 per cent. of dioxide, double the quantity should be taken. For decomposition, about 40 cc. of hydrogen peroxide, as ordinarily used, are required.

(b.) *The volumetric method.* A measured quantity of standardised hydrogen peroxide is added to the finely-powdered pyrolusite, and the excess ascertained by titration with standard potassium permanganate solution. The details as recommended are as follows:—The permanganate solution is made by dissolving 6—10 grms. of potassium permanganate in a litre of water and titrating by any known method. The hydrogen peroxide generally brought into the market is too concentrated; 5 cc. should therefore be titrated with the permanganate solution, and then so much dilute sulphuric acid (1:10) should be added to the hydrogen peroxide as will make this solution approximately equivalent to the permanganate solution. For analysis 0.4—1 gm. of the finely-powdered ore is introduced into a flask or tall beaker; to this exactly 50 cc. of the prepared hydrogen peroxide solution are added, and the whole is then allowed to remain for about half an hour, being shaken from time to time. At the end of this time the excess of hydrogen peroxide is ascertained by means of the permanganate solution. In the case of ores giving a turbid brown liquid, titration is difficult. Hence to obtain accurate results the weighed sample is introduced into a 100 cc. flask, the 50 cc. of hydrogen peroxide are run in, and the whole is allowed to stand for half an hour, after which the flask is filled to the containing mark, and the contents are filtered through a double filter; 50 cc. of the filtrate are then titrated. This method admits of quite a number of determinations being carried on at the same time. Ores containing ferrous oxide may not be examined by this method, it is obvious.

(c.) *The gasometric method.*

At 0° C. and 760 mm. barometric pressure 100 cc. of oxygen are obtained, according to the equation already given, from 0.38825 gm. of manganese dioxide; hence 0.1 cc. represents 0.1 per cent. Thus it will not do to use a collecting vessel of only 50 cc. capacity, using half the quantity of pyrolusite; the errors of experiment become much too high. The endiometer or burette used (of whatever kind it be) should be capable of measuring up to 100 cc., and should be provided with a water-jacket. The decomposition apparatus consists of a test-tube provided

with doubly-bored stopper, through one hole of which passes a glass rod with, fused to its inner end, a small vessel capable of holding 10 cc. of hydrogen peroxide; through the other hole of the stopper passes a glass delivery tube provided with a tap, and connected with the gas burette by means of rubber tubing. The ore is accurately weighed into the test-tube, and to it are added 20 cc. of dilute sulphuric acid; 10 cc. of hydrogen peroxide are filled into the small vessel fastened to the stopper, and the stopper is then fixed into position. Before connecting with the gas burette the

decomposition apparatus is brought to the temperature of the gas burette. The reaction is easily brought about by tilting the decomposition apparatus, whereby the hydrogen peroxide is caused to run from its containing vessel. Water is used in the burette. As regards calculation of results, it is first necessary to reduce to 0° C. and 760 mm. barometric pressure, and then to multiply by the factor for converting oxygen to manganese dioxide. Both these may be performed, with the aid of the accompanying table, by a single multiplication.

WEIGHT OF MANGANESE DIOXIDE IN MGMS. CORRESPONDING TO 1 CC. OF OXYGEN AT TEMPERATURES VARYING FROM 10° C. to 25° C., AND PRESSURES VARYING FROM 700 to 770 MM.

$$\text{Calculated from } \frac{(p - w) 3.8825}{760 (1 + 0.00366t)}$$

(Between 10° and 12° subtract 1 mm. from observed barometric height; between 13° and 19°, 2 mm.; between 20° and 25°, 3 mm., for reduction of the mercury column to 0° C.)

The author maintains that for accurate work a reduction apparatus should not be used. He also asserts that in calculating the results the factor of Liebig and Lunge ought not to be used, as being too high.

The accompanying table may also be so used that much trouble in calculating results is saved, thus:—By putting the decimal point in the table two figures to the right, the weight of manganese dioxide is ascertained, which, at the particular temperature and pressure specified, gives 100 cc. of oxygen. It is only necessary, therefore, before the experiment, to read the temperature of the jackets and the barometric pressure, and to weigh out exactly the amount of ore ascertained as explained; the oxygen evolved then shows directly the percentage of manganese dioxide in the sample. All the methods described are said to give good results.

—T. L. B.

*Tables for Strength of Potassium Permanganate Solution, and for use in the Valuation of Bleach.* L. Vanino. Zeits. f. angew. Chem. 1890, 80—83.

1. *Potassium Permanganate.*—The reaction with hydrogen peroxide is represented by the equation—

According to concentration 10 to 50 cc. of permanganate solution are treated with hydrogen peroxide and the oxygen evolved is measured in a Wagner's "azotometer." The calculation of results is simplified by making use of the accompanying table.

TABLE I.—WEIGHT OF 1 CC. OF OXYGEN IN MGMS. AT TEMPERATURES VARYING FROM 10° C. TO 25° C., AND PRESSURES VARYING FROM 700 TO 770 MM.

Calculated from $(p - w) \cdot 1.42908$ 760 (1 + 0.00366t)								(Barometric reading to be reduced as indicated in Table on p. 551.)

*Rapid Method for the Estimation of Phosphorus in Iron and Steel.* G. L. Norris. J. Frank. Inst. 1890, 99, 72—74.

This is a modification of Drown's method (Am. Inst. Min. Eng. June 1889). 5 grms. of pig iron or steel are treated in a 12-oz. beaker with nitric acid of sp. gr. 1·135, using 90 cc.

for steels and 120 cc. for pig irons. The beaker is heated until solution is complete and the acid boils, 20 cc. of a solution of potassium permanganate (containing 8 grms. of the salt per litre) are then added, and the boiling continued for a few minutes. A precipitate of manganese peroxide should be formed. The latter is then dissolved by the addition of

a crystal of tartaric acid, and 10 cc. of nitric acid sp. gr. 1.40 are added. The solution should then measure about 90 cc. In the case of a pig iron the solution is diluted to 100 cc. before the addition of the nitric acid, filtered, and the nitric acid added to 80 cc. of the filtrate. The liquid is transferred to a 500 cc. flask, 80 cc. of a solution of ammonium molybdate added, and the whole violently shaken for five minutes. The precipitate is then reduced with zinc and titrated with permanganate of potassium in the usual way. The molybdate solution is prepared by dissolving 100 grms. of molybdic acid in 400 cc. of strong ammonia, and adding the solution to 1,200 cc. of nitric acid sp. gr. 1.20.

For "high phosphorus pig-iron" only 1.25 grms. are weighed out and dissolved in 60 cc. of the nitric acid, and the solution treated as before. The whole analysis can be made in 35 minutes. Tables of results accompany the paper.—H. K. T.

#### *The Volumetric Determination of Zinc and Copper.*

E. Donath and G. Hattensaur. Chem. Zeit. 14, 323—325.

THE authors find that the use of standard sodium sulphide solution prepared by saturating caustic soda solution with sulphuretted hydrogen and then adding an equal volume of caustic soda, is to be preferred to the use of crystallised sodium sulphide for titrating zinc. The method of precipitating zinc with an excess of potassium ferrocyanide and estimating the excess of the latter by permanganate was abandoned as the precipitate did not settle readily and the clear liquid could not be decanted. The authors recommend the precipitation of zinc in an ammoniacal tartaric acid solution with potassium ferrocyanide. Ferric oxide is not precipitated in such a solution. The solution should not be too strongly alkaline, and the addition of ferrocyanide should take place in the hot solution. The reaction is complete when a drop of the solution acidified with acetic acid gives a blue colouration supposing iron to be previously present in the solution. 1 mol. of ferrocyanide is equivalent to 2 atoms of zinc, and therefore 33.5 grms. of ferrocyanide in 1 litre correspond to 10 grms. of zinc, or 1 cc. is equivalent to .010 gm. of zinc. The operation is carried out as follows: 3—4 grms. of the ore, &c. are dissolved in concentrated hydrochloric acid, with the addition of nitric acid, filtered, and diluted to a given volume. A measured portion is withdrawn, 20—25 cc. of a concentrated tartaric acid solution added, and then ammonia until alkaline. The solution is heated to 80°, and potassium ferrocyanide run in from a burette, the end of the reaction being determined as above.

Copper may be estimated in the same way, but the precipitation is greatly dependent upon the amount of ammonia present. The solution should be as nearly neutral as possible. The equivalent in copper of the ferrocyanide must be determined by direct experiment as no definite copper compound is precipitated. The end of the reaction is recognised in the same way as for zinc. This method enables the zinc and copper to be estimated in the same solution. The two are first titrated together, the copper is then precipitated with iron and the clear solution, after oxidation of the iron, again titrated for zinc.—J. B. C.

#### *The Estimation of Cadmium in the Products of Zinc Manufacture.* W. Minor. Chem. Zeit. 14, 348—349.

IN this paper the author gives a direct and an indirect method for the determination of cadmium. In the indirect method, the sample to be analysed is dissolved in hydrochloric acid, filtered from undissolved lead, and precipitated with sulphuretted hydrogen. The precipitate of cadmium sulphide, containing more or less zinc sulphide, is filtered off and weighed. It is then dissolved in hydrochloric acid, the solution is rendered strongly alkaline with caustic soda, and filtered from the precipitated cadmium hydrate. In the filtrate the zinc is determined by titration with sodium sulphide. The zinc found is calculated into sulphide and deducted from the weight of the cadmium sulphide precipitate. In the direct method the cadmium must be separated

in a state of purity and converted into neutral cadmium chloride. The solution of the cadmium salt is then titrated with standard sodium hydrate, using sodium sulphide paper or litmus paper as an indicator. The direct method is preferably used in the case of nearly pure cadmium compounds, whilst the indirect method is most suitable in the case of bodies containing much zinc. The test analyses given are quite satisfactory. (See also this Journal, 1890, 109.)—H. T. P.

#### *Quantitative Separation of Tin and Titanium, with Special Reference to the Analysis of Silicates.* A. Hilger and H. Haas. Ber. 23, 458—461.

FOR the separation of tin and titanium the mixed oxides are placed in a hard glass tube 15—20 cm. in length and heated in a current of hydrogen by a Bunsen burner for a quarter of an hour. The stannic oxide is thus reduced to metal, whilst the titanium dioxide remains unacted upon. The mixture is washed with water and a few drops of hydrochloric acid into a beaker, 30 cc. of 20 per cent. hydrochloric acid are added, and the whole boiled gently for half an hour, filtered, and washed. The tin contained in the filtrate is precipitated as sulphide, the precipitate washed with water containing ammonium acetate, again reduced in a current of hydrogen, and the resulting metal converted into the dioxide by means of nitric acid and weighed. The residue of titanic oxide on the filter, together with the filter paper, is ignited and fused with 10 times its own weight of potassium carbonate. The fused mass is next treated with about 200 cc. of water, and concentrated sulphuric acid is added drop by drop until the acid potassium titanate is dissolved, the solution then being neutralised with sodium carbonate; finally 2 grms. of concentrated sulphuric acid are added, the whole made up to 400 cc. and boiled for six hours. Titanic acid is precipitated, and is washed, dried, and weighed as the dioxide. The accuracy of the method is confirmed by a series of analyses given. To apply it to silicates the following method of procedure has been adopted as the result of many trials:—5—10 grms. of the mineral are decomposed by strong hydrofluoric acid, and the resulting solution, after neutralisation with sodium or potassium hydrate, treated with 2 cc. of sulphuric acid (conc.) and boiled for six hours after dilution to 400 cc. The hydrated oxides of tin and titanium are completely precipitated and can be separated as above described. Should any iron remain with the titanic oxide it can be readily removed by repeating the reduction in hydrogen and treatment with hydrochloric acid.

—C. A. K.

#### *Tests for Phenacetin.* S. Lüttke. Pharm. C. H. N. F. 1890, 65.

THE ortho-compound of phenacetin, diamidophenols, and diamidophenetols may occur as impurities in phenacetin. To determine the presence of the ortho-compound, 15 grms. are boiled with 25 grms. of dilute hydrochloric acid. Amidophenetol hydrochloride is formed, which may be separated with caustic soda, and its boiling-point (242.5°) determined. The hydrochloride of amidophenetol gives, with ferric chloride, a blood-red colouration. To detect the presence of diamido-compounds, 0.5 gm. of bleaching powder is ground with hydrochloric acid to a thin paste, and a few centigrams. of powdered phenacetin added. A red colouration indicates the presence of diamido-compounds.

—J. B. C.

#### *Tests for Quinine.* E. Hirschsohn. Pharm. Zeit. Russl. 1890, 1.

IN order to test the purity of quinine sulphate, 0.2 gm. of that salt is shaken with 5 cc. of a mixture of 30 vols. of petroleum ether (sp. gr. 0.680) and 70 vols. of chloroform, and filtered. To the clear filtrate 3 vols. of petroleum ether

are added. With pure quinine sulphate the liquid remains clear, whereas in the presence of any other alkaloid an opalescence or precipitate is formed.—J. B. C.

*Method of distinguishing Exalgin from Antifebrin and Phenacetin.* E. Hirschsohn. Pharm. Zeit. Russl. 1890, 17.

METHYLACETANILIDE, or exalgin, may be readily distinguished from antifebrin and phenacetin by its greater solubility in chloroform.

One grm. of exalgin dissolves completely in 2 cc. of chloroform in the cold. Antifebrin and phenacetin remain undissolved.

The two latter may be distinguished by their behaviour towards bromine water. Antifebrin yields crystalline acetparabromanilide. In the case of phenacetin, no separation is effected. The use of chloroform may also be used to detect the presence of 10 per cent. of phenacetin or 20 per cent. of antifebrin in a sample of exalgin.—J. B. C.

*The Use of Mercuric Nitrate containing Nitrous Acid as a Reagent for Phenols.* L. C. Plugge. Arch. Pharm. 1890, 9.

THE above reagent gives with a dilute solution of phenol a violet-red colour. This reaction is not limited to phenol, but occurs also with other hydroxy-derivatives of benzene. The position of the hydroxyl group with respect to other side chains appears to have no influence.—J. B. C.

*New Reaction for Nitrogen in Organic Compounds.* E. Donath. Chem. Zeit. 14, 157—158.

IT is known that organic substances containing nitrogen suffer decomposition more or less severely when heated with concentrated sulphuric acid. If, as in the case of Kjeldahl's method, a powerful oxidising agent is present at the same time, combustion of the carbon and part of the hydrogen ensues, whilst the nitrogen atoms present, so to speak, in a nascent state, combine with an equivalent number of hydrogen atoms to form ammonia. By reversing this reaction and effecting the decomposition by means of an active base in the presence of a powerful oxidising agent, it may be inferred that the nitrogen would combine with the oxygen to form an acid. Upon this assumption the author has made an extensive series of determinations with a large number of substances representing the most important groups of organic nitrogenous compounds. In each case nitrous acid was the product of the reaction, a result which leaves but little doubt as to the general applicability of this new reaction.—D. B.

*Pyridine Bases and Wood Fibre.* A. Ihl. Chem. Zeit. 14, 304.

THE author has examined the action of various pyridine bases, occurring in animal oil, on wood. Wood, moistened with an alcoholic solution of pyrrol ( $C_4H_5N$ ), and then with hydrochloric acid, assumes an intense carmine-red colour, which gradually deepens in tint. Paper containing wood cellulose gives the same reaction. Pyridine,  $C_5H_5N$ , under the same circumstances colours wood a pale pink. Picoline,  $C_5H_7(CH_3)N$ , gives, after some time, a slight yellow colour. Lutidine,  $C_6H_9(CH_3)_2N$ , has the same effect as picoline. Collidine could not be obtained, but it is present in commercial "pyridine bases," and is a colourless fluid. Wood, treated with an alcoholic solution of this fluid, followed by hydrochloric acid, becomes after some time of an orange-yellow colour. Collidine itself, therefore, can only produce a more or less yellow tint. The red colour which animal oil and tobacco juice impart to wood can thus be only ascribed

to the presence of pyrrol. During the dry distillation of albuminoids and kindred bodies pyrrol is always produced, and may be readily detected by its action on wood.

—H. T. P.

*The Colour Reactions of Carbon Compounds. Pyrrol Colours producible on the Fibre.* A. Ihl. Chem. Zeit. 14, 348.

THE author has observed the behaviour of various allyl compounds with phloroglucinol and pyrrol.

Dilute allyl alcohol boiled with phloroglucinol and a large excess of hydrochloric acid, assumes after some time a yellowish-red colour. Strong sulphuric acid acts on strong and weak solutions of allyl alcohol in the same way that it acts on saccharose. Allylsulphide, diluted with alcohol, yields, on warming with phloroglucinol and an excess of hydrochloric acid, a red colouration. Allyl mustard-oil, similarly treated, gives already in the cold a pale red colouration, which deepens on warming. Allylsulphide treated with an alcoholic solution of pyrrol, and strong hydrochloric acid, develops a cochineal-red colour, whilst allyl mustard-oil under similar circumstances assumes a paler red tint. Bitter almond-oil, dissolved in alcohol and mixed with an alcoholic pyrrol solution and hydrochloric acid, deposits a white precipitate, which rapidly turns grey, pale red, and finally bright carmine-red. The precipitate is a condensation product of pyrrol and benzaldehyde. Cotton cloth, dipped in a weak alcoholic solution of bitter almond-oil, and then treated with alcoholic pyrrol solution, ferric chloride, and hydrochloric acid, and gently warmed, is coloured red. White tissues similarly treated with oil of cinnamon, pyrrol, ferric chloride, and hydrochloric acid, are dyed a deep black.—H. T. P.

*A New Reaction for Tannin.* C. Böttger. Ann. 256, 341—344.

TANNIN reacts with phenylhydrazine, though not forming so elegant a test as gallic acid does. The substances are boiled together in aqueous solution, in the proportion by weight of 2:1, or better 1:1, or are heated together at 100° directly, with exclusion of water, in the proportion of 1:2, with subsequent treatment with water and heating to boiling. In either case solution is effected. Carbon dioxide escapes, and there are formed substances of the nature of colouring matters, which are either insoluble or with difficulty soluble in water, and evidently the result of a secondary reaction. Some of these substances are easily soluble, the rest insoluble in ether. The latter are also not completely soluble in caustic soda solution; the alcoholic-etheral solution of the former is quickly decolourised by zinc dust and a few drops of hydrochloric acid.

The principal product of the reaction described, is itself a mixture of several bodies. It is soluble in ether and in hot water, and possesses the property, on cautious treatment with caustic soda, of yielding a splendid green-blue solution, gradually turning yellow.

To obtain this reaction it is only necessary to boil the solution of the tannin for a little time with phenylhydrazine. Neither gallic acid nor pyrogallol give this reaction.

The author next describes a method for isolating the substance which gives the blue colour.

Gallic acid-phenylhydrazide, dissolves in caustic soda solution, giving a reddish-yellow, orange, or golden colouration.

*The Estimation of Tartaric Acid in the Crude Products of Tartaric Acid Manufacture.* P. Telbisz. Chem. Zeit. 14, 347.

TÓTH's recent work on the estimation of tartaric acid in raw materials (this Journal, 1890, 420—421) by the Goldenberg-Geromont, Goldenberg-Geromont modified, and Lorenz methods; but especially the conclusion derivable from Tóth's results, that the largely-used and modified Golden-

berg-Geromont method is unsatisfactory, induced the author to estimate the tartaric acid in a number of samples of crude calcium tartrate and wine-lees by the above methods. The following results were obtained :—

## CALCIUM TARTRATES.

No. of Sample.	Tartar according to the Goldenberg-Geromont Method.	Differences.	Tartar by the Modified Goldenberg-Geromont Method.	Differences.	Tartar by the Lorenz Method.	Differences.
	Per Cent.		Per Cent.		Per Cent.	
1	59'00 } 59'40 } 58'80 }	0'60	59'10 } 59'30 } 59'30 }	0'20	60'80 } 60'70 }	0'10
2	53'20 } 53'40 }	0'20	52'17 } 52'31 }	0'14	56'03 } 56'22 }	0'19
3	63'60 } 63'80 }	0'20	62'45 } 62'62 }	0'17	64'87 } 64'87 }	0'06
4	56'60 } 57'00 }	0'10	54'84 } 55'26 }	0'52	56'91 } 56'56 }	0'35
5	59'60 } 59'20 }	0'20	56'39 } 56'22 }	0'17	60'55 } 60'89 }	0'34

## DRY WINE LEES.

No. of Sample.	Tartar by the Goldenberg-Geromont Method.	Differences.	Tartar by the Modified Goldenberg-Geromont Method.	Differences.	Tartar by the Lorenz Method.	Differences.
	Per Cent.		Per Cent.		Per Cent.	
1	25'00 } 23'40 }	0'40	22'54 } 22'36 } 22'54 }	0'18	25'95 } 25'46 }	0'52
2	30'10 } 30'40 }	0'30	28'45 } 28'22 }	0'23	30'44 } 29'95 }	0'49

According to Wolfmann, the results obtained by the second of these methods agree best with the yield of tartar obtained on the large scale. The author is, therefore, of opinion that the modified Goldenberg-Geromont method is, for the present, at least, the most accurate. The results also show that differences of 7—10 per cent. between the results of different analyses of the same sample, as were found by Tóth, should never occur.—H. T. P.

*Volumetric Estimation of Tannin in Wines.* L. Roos, Cusson, and Giraud. *J. Pharm. Chim.* 1890, **21**, 59.

THE reagent used is a 10 per cent. tartaric acid solution to which ammonia is added until faintly alkaline. Neutral lead acetate is now added until the precipitate no longer redissolves, when the solution is filtered.

This solution precipitates tannin completely from its solutions. To 25 cc. of a tannin solution, which contains 5 grms. to the litre, 4—5 drops of ammonia, and for a preliminary estimation 2 cc. of the lead solution are added at a time. A drop of the solution is placed after each addition on paper, and a drop of sodium sulphide solution added. When a brown colouration is produced the end of the reaction is attained. In the case of wines 25 cc. are employed, made faintly alkaline with ammonia, and the operation conducted as above.—J. B. C.

*Quantitative Estimation of Codeine and Morphine.* E. Claassen. *Pharm. Rund.* 1890, **41**. (See this Journal 1890, 423.)

IF the free alkaloid alone is present without ammonium salts or substances, which decompose ammonium chloride, the codeine is heated in a flask with ammonium chloride and the ammonia, which is set free, collected in standard hydrochloric acid solution and titrated. 100 parts of  $\text{Nl}_3$  correspond to 1758'8 parts of anhydrous codeine. Or the following method may be adopted:—The liquid is acidified with dilute sulphuric acid and evaporated with excess of magnesia to dryness. The residue is extracted with alcohol, the latter distilled off and the residue treated as above with ammonium chloride. The residual liquid in the flask is acidified with hydrochloric acid and morphine, precipitated by the slightest possible excess of ammonia and weighed on a filter paper. As the codeine remains in the solution after extracting the morphine, the solution may be evaporated with magnesia and the codeine extracted with ether. When the ether has been driven off, morphine sulphate is added, and then from the amount of precipitated morphine that of the codeine may be calculated.—J. B. C.

*Estimation of Nitrogen in Organic Substances by use of Alkaline Potassium Permanganate.* R. L. Wagner. *Chem. Zeit.* **14**, 269.

THE communication by E. Donath (page 555) has led the author to communicate the following earlier research:—In the winter session 1885—86, in the laboratory of the

Leipzig Agricultural Institute, he estimated nitrogen in organic substances by the use of an alkaline solution of potassium permanganate. A note of previous publications of others on the subject is given. The substance and the alkaline solution of potassium permanganate were enclosed in a sealed tube 20—30 cm. long. There being a large evolution of oxygen with very oxidisable bodies, one end of the tube terminated in a short capillary tube. The tubes were heated in a sloping oven, the temperature being maintained at  $150^{\circ}$ — $170^{\circ}$  for 2—2½ hours. The substances were previously intimately mixed by heating on a water-bath and shaking vigorously. At the end of the operation the glass tube was opened, and the contents transferred to a porcelain basin. The contents were then reduced by heating with the requisite quantity of manganese sulphate solution and sodium carbonate. The filtrate from the manganese precipitate was washed with warm dilute soda solution, and concentrated in a 200—250 cc. flask over a small flame. The potassium nitrate was then estimated by the method of Eder (Zeits. Anal. Chem. 1877, 16).

In these experiments, 0·65 to 0·1 gm. of substance was mixed with 25—30 times the amount of potassium permanganate, and 5 cc. of solution containing 25 per cent. of pure potassium hydrate.

When too little time is allowed for the oxidation, ammonia and nitrite remain, and loss is shown on estimation of the nitrate.

Many bodies in which the nitrogen is combined with carbon or hydrogen being insoluble in solutions of salts and alkalis, could only be incompletely oxidised. This process is of practical value only for pure nitro-derivatives and nitric ethers. Those which are not volatile and are soluble in alkaline solution can be treated with the alkaline permanganate in a porcelain basin.

It is also a good plan to reduce the excess of permanganate with alcohol, and then to convert the nitrogen as nitrate or nitrite into ammonia. In order to do this the whole filtrate, about 100—150 cc., are placed in a 600—750 cc. round flask, 2 grms. of dissolved ferrous sulphate and about 1—2 grms. of zinc dust are added and agitated, and then neutralised with hydrochloric acid. The nitrogen acids are, on gentle warming, converted into ammonia in a few minutes, and this can be estimated by means of decinormal acid in the usual way.

The following are some of the author's results:—

	Calculated.	Found.
1. Calculated from nitric acid found—	Per Cent.	Per Cent.
Ammonium sulphate $(\text{NH}_4)_2\text{SO}_4$ .....	21·20	20·80
Asparagin $\text{C}_4\text{H}_8\text{N}_2\text{O}_3 + \text{H}_2\text{O}$ .....	18·66	18·51
Leucine $\text{C}_6\text{H}_{10}(\text{NH}_2)\text{COOH}$ .....	10·71	10·60
Caffeine $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2 + \text{H}_2\text{O}$ .....	26·44	26·31
Potassium ferrocyanide $\text{K}_4\text{FeC}_6\text{N}_6 + 3 \text{H}_2\text{O}$ .....	19·93	19·83
Quinine $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_5$ , dried at $110^{\circ}$ .....	8·67	8·75
Brucine cryst. $\text{C}_{23}\text{H}_{26}\text{N}_2\text{O}_4 + 4 \text{H}_2\text{O}$ .....	6·01	6·12
Trinitrophenol $\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OH}$ .....	18·34	18·30
Nitrobenzene $\text{C}_6\text{H}_5\text{NO}_2$ .....	11·38	11·42
White of egg .....	15·65	14·42
Uric acid $\text{C}_5\text{H}_4\text{N}_4\text{O}_3$ .....	33·40	30·20
Aniline hydrochloride $\text{C}_6\text{H}_5\text{NH}_2\text{Cl}$ .....	10·81	7·60
2. From ammonia found—		
<i>o</i> -Nitrophenol $\text{C}_6\text{H}_4(\text{NO}_2)\text{OH}$ .....	10·07	10·01
<i>p</i> -Dinitroresol $\text{C}_6\text{H}_3(\text{NO}_2)_2\text{CH}_3\text{OH}$ .....	14·14	14·10
<i>o</i> -Nitrobenzoic acid $\text{C}_6\text{H}_4(\text{NO}_2)\text{COOH}$ ...	8·38	8·27
Collodion .....	..	10·62
Gun-cotton .....	..	13·11

These last were estimated in the autumn of 1887. The oxidation was effected in a porcelain basin on the water-bath.

The author also estimated the sulphur contained in carbon bisulphide and in thiophen.

0·05 to 0·1 gm. of each liquid was enclosed in a very thin glass bulb which was broken by a strong shake when enclosed and sealed in the glass tube.

	Calculated.	Found.
Carbon disulphide $\text{CS}_2$ .....	Per Cent. 81·2	Per Cent. Sulphur. 81·08
Thiophen $\text{C}_4\text{H}_4\text{S}$ .....	38·09	38·16

—D. A. S.

*A New Method of Estimating Alcohol by Means of Chromic Acid.* R. Bourcart. Bull. Ind. Soc. Mulhouse, 1889, 558—562.

THE method of determining alcohol, previously described by the author, in which an oxidising mixture of potassium permanganate and strong sulphuric acid was used, is liable to give erroneous results, due partly to the difficulty of controlling the oxidation and partly to the spontaneous decomposition of the mixture when heated above  $50^{\circ}$ , or when kept any length of time before dilution with water. These drawbacks are not met with when a mixture of dilute solutions of potassium bichromate and sulphuric acid is employed. Such a mixture can be boiled for a long time without decomposition.

The determination of the alcohol is made by heating a small quantity of the sample with an excess of the oxidising mixture in a sealed tube, or more conveniently, to save the trouble of sealing and opening, in a well-corked tube, weighted or tied down, the tube being first shaken to mix the contents, and then heated on the water-bath for two or three hours. After cooling, the contents of the tube are collected in a flask, the tube rinsed out with water, and the excess of potassium bichromate determined with potassium iodide, sodium thiosulphate, and starch-paste. Experiments were made under slightly varying conditions, with 10 cc. of a dilute solution of alcohol, obtained by diluting with 200 volumes of water, 1 volume of alcohol of sp. gr. 0·7997 at  $15^{\circ}5'$ , containing 98·8 per cent. by volume according to Traill's tables. Very regular results were obtained, the mean assigning to the alcohol a percentage by volume of 97·3086. In most of the trial experiments there were used for 10 cc. of the dilute alcohol, 50 cc. of a 0·5 solution of potassium bichromate, and 10 cc. of 25 per cent. sulphuric acid; after heating, 10 cc. of a 10 per cent. solution of potassium iodide were added, then the liquid was titrated with sodium thiosulphate till its dirty-yellow colour changed to a green-yellow, when the starch-paste was added, and the titration was continued till the purple colour had disappeared, leaving the liquid a pale blue, due to the presence of chrome alum.

Estimating aldehyde in a similar way and calculating from the basis of three molecules of aldehyde being oxidised to acetic acid by one molecule of potassium bichromate, there were found respectively in two experiments, 1·2603 and 1·2549 grms., the amount taken being 1·2424 gm. of paraldehyde.

It was further ascertained that the oxidising mixture had no influence on acetic acid, the full amount of potassium bichromate used being found unchanged after prolonged heating in the tube.—E. B.

*Method for Detecting and Estimating Petroleum in Oil of Turpentine.* W. M. Burton. Amer. Chem. J. 12, 102—104.

REFERRING to Armstrong's method for the detection of petroleum in turpentine oil, which depends on the ready and nearly complete polymerisation of oil of turpentine by

sulphuric acid, and the comparative indifference to such treatment of petroleum, the author finds that this process does not merely take up much time and labour, but the yield of petroleum is far from being quantitative, leaving the operator in the dark as to the extent of the adulteration.

The method proposed by the author is based on the fact that petroleum is only slightly affected by fuming nitric acid in the cold, whilst oil of turpentine is readily oxidised to various acids of the fatty and aromatic series which are soluble in hot water. The apparatus necessary for effecting this separation consists of a balloon flask of 750 cc. capacity, which is fitted with a two-holed cork stopper. Through one hole is inserted the tube of a glass-stoppered drop funnel having a capacity of 100 cc. The flask is also connected with an inverted condenser. About 300 cc. of fuming nitric acid of sp. gr. 1.4 are placed in the flask, and 100 cc. of the oil of turpentine under examination are measured into the drop-funnel. The flask is surrounded by cold water, and the turpentine is allowed to drop slowly into the nitric acid. As each drop strikes the acid, violent action takes place with evolution of red fumes. It is well to shake the flask occasionally during the operation. When the turpentine oil has all passed into the flask the apparatus is allowed to stand until all action is over. The contents are transferred to a large separating funnel and treated with successive portions of hot water. In this way all the products resulting from the action of the acid on the terpenes are removed, whilst any petroleum paraffins remain insoluble in water and can be readily separated and measured.—D. B.

## New Books.

**DIE TIHERFARBEN MIT BESONDERER RÜCKSICHT AUF SCHÄDLICHKEIT UND GESETZGEBUNG HYGIENISCH UND FORENSISCH-CHEMISCH UNTERSUCHT, VON DR. TH. WEYL.** Mit einer Vorrede von PROF. DR. ECG. SELL. Berlin: Verlag von August Hirschwald. Unter den Linden, 68, N.W. London: H. Grevel and Co., 33, King Street, Covent Garden.

The whole work includes two 8vo parts, bound in pamphlet form, price 2s. 8d. each, and each complete in itself; Part I. containing its own Alphabetical Index, whilst Part II. contains a General Index. Part I. commences with Dr. Sell's introductory remarks, and these are followed by the Preface, Table of Contents, and 77 pages of Subject-matter. In Chapter I. the Coal Tar Colours are treated of, both chemically and technologically. Chapter II. deals with the Poisonous Tar Colours. Chapter III. with the laws against the Employment of Poisonous Colours. Chapter IV. Problems for Investigation. Chapter V. Method of Conducting the Investigations as to Poisonous Properties and Power.

**SPECIAL SECTION.**—Chap. I. Nitroso Colours. Chap. II. Nitro Colours.

**PART II.**—This is really a continuation of the Special Section concluding Part I., and the whole pamphlet, which comprises pages 81 to 138, and concludes with a General Alphabetical Index, is devoted to the consideration of the Subject-matter of Chapter III., which deals with the Azo-Colours. In this chapter, *first*, a chemical review is made of this class of colouring matters, their constitution, properties, and modes of employment—the textile arts, and *second*, a systematic report of the experiments tried with the representative members of the principal series of Azo-Colours. The conclusions drawn from the investigations are recorded on pages 136—137.

**YEAR BOOK OF THE SCIENTIFIC AND LEARNED SOCIETIES OF GREAT BRITAIN AND IRELAND.** Comprising Lists of the Papers read during 1889 before Societies engaged in Fourteen Departments of Research, with the names of their Authors. Compiled from Official Sources. Seventh Annual Issue. London: Chas. Griffin and Co., Exeter Street, Strand. 1890.

OCTAVO volume, bound in red cloth, and containing Preface, Synopsis of Contents, Subject-matter covering 220 pages, and an Alphabetical Index. A reference to the pages of the Year Book show that the subjects represented by the various Societies are as follows:—1. Science Generally. 2. Astronomy, Mathematics, and Physics. 3. Chemistry and Photography. 4. Geography, Geology, and Mineralogy. 5. Biology. 6. Economic Science. 7. Mechanical Science. 8. Naval and Military Science. 9. Agriculture. 10. Law. 11. Literature and History. 12. Psychology. 13. Archaeology. 14. Medicine.

**GASANALYTISCHE METHODEN.** VON DR. WALTHER HEMPEL, Professor an der Technischen Hochschule zu Dresden. Zweite Auflage. 1890. Braunschweig: Friedrich Vieweg und Sohn. London: H. Grevel and Co., 33, King Street, Covent Garden.

THIS, the second edition of Hempel's Methods of Gas Analysis, is an 8vo volume of considerably greater dimensions than the first edition. It is bound in paper cover, and the price is 11s. The work, which is illustrated with 101 excellent engravings, commences with a short preface by the author, in which the latter, whilst disclaiming any intention of going into detail on the subject of Methods of Gas Analysis, states it as his desire to make his book valuable as a laboratory guide. He has, however, made an exception in favour of Pettersson's apparatus, because the operation of this instrument involves the application of a completely new principle with regard to the measurement of gases. The text covers 364 pages, and the work terminates with an Alphabetical Index and List of Corrigenda.

The Subject-matter of the text is divided into three sections. PART I. General Methods; PART II. Special Methods; and PART III. Applications of Gas Analysis. In PART III. the subject of Chimney Gases is first dealt with, and thereafter Illuminating Gas, Water Gas, Generator Gas, and Coke-oven Gases. Then follows Photometry, with the amyl-acetate lamp of Hefner-Alteneck recommended as an instrument for furnishing the unit of light. It is claimed as its great advantage that when once regulated and lighted it continues to burn for a long time unaltered in intensity. Estimation of Specific Gravity (Bunsen and Schilling). Lux's Gas Balance. Examples given and worked out both of Illuminating and Water Gas. Estimation of Tar in Crude Gases (Tieftrunk), of Sulphuretted Hydrogen in Gas (Bunte), of Total Sulphur (Drehschmidt), and Carbonic Acid (Rüdorff).

Pages 240—246 are devoted to the methods for determining the gases employed in the Sulphuric Acid Chamber; pp. 246—285 the Gaseous Constituents of Atmospheric Air; and page 312 the Estimation of Fluorine as Fluor-silicic. The latter part of the work is devoted to important methods and apparatus for the Analysis of Nitre and Nitric Ether, Nitroglycerol, Gun-cotton, &c., and finally a method for the Estimation of the Calorific Value of Fuels.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

#### ITALY.

##### Classification of Articles in Customs Tariff.

*Note.*—Lire =  $9\frac{9}{16}$ d. Quintal = 220·4 lb. avoirdupois.  
Hectogramme = 3·52 oz.

The following decisions affecting the classification of articles in the Italian Customs tariff have recently been given by the Italian Customs authorities :—

Rye-straw paste prepared with nitrates and hydrates (an explosive).—Category 51 B. Duty, 4 lire per quintal.

India-rubber, not prepared.—Category 334 A. Duty free.  
Oil of cherry laurel.—Category 61. Duty, 10 lire per quintal.

#### GREECE.

##### Modifications in Customs Duties on Imports from the United Kingdom.

*Note.*—Drachme = 100 Lepta =  $9\frac{9}{16}$ d. Oke = 2·84 lb. avoirdupois.

The following is a statement of some of the modifications (in accordance with the agreement of the 28th March 1890) in the Greek Customs tariff in favour of goods, the produce or manufacture of the United Kingdom, imported into Greece :—

*Vegetable Dyes.*—Class 59 (b).—Indigo.—Duty of 3 drachmes per oke, reduced to 10 leptas.

*Chemical Products.*—Class 103 (c).—Acids, pure, *i.e.*, sulphuric acid (vitriol), hydrochloric acid (spirits of salts), nitric acid (aqua fortis), phenic acid, and other similar acids, as well as all other chemical products not specially mentioned.—Duty of 20 leptas per oke, reduced to 10 leptas.

Class 103 (d).—Impure acids (so-called acids of commerce).—Duty of 10 leptas per oke, abolished.

#### UNITED STATES.

##### Recent Customs Decisions.

The following decisions affecting the classification of articles in the Customs tariff and the application of the Customs Law of the United States have recently been given by the United States Customs authorities :—

A solid expressed or rendered oil, obtained from some unknown vegetable source, probably the palm-nut, rapeseed, or other like substance, assimilating to cocoa butter in appearance, and the uses to which it may be applied, is dutiable at the rate of 25 per cent. *ad valorem*.

Essential oils of mustard and wintergreen are dutiable at the rate of 25 per cent. *ad valorem*.

#### CANADA.

##### Modifications in the Customs Tariff.

The following is a list of changes which have recently been made in the Customs tariff of Canada. The rearrangement of classification and the duties on the articles

enumerated below are to be substituted for those hitherto in force :—

Classification of Articles.	Rates of Duty.
	Dols. Cts.
Acid, acetic and pyroligneous, not otherwise specified, and vinegar, for each gallon of any strength not exceeding a strength of proof. . . . .	Per gall. 0·15
For each degree of strength in excess of the strength of proof an additional duty of 1 cent. The strength of proof shall be held to be equal to 6 per cent. of absolute acid, and in all cases the strength shall be determined in such manner as may be established by the Governor in Council.	
Acid, acetic and pyroligneous, of any strength, when imported by dyers, calico printers, or manufacturers of acetates or colours, for exclusive use in dyeing or printing, or for the manufacture of such acetates or colours in their own factories, under such regulations as may be established by the Governor in Council. . . . .	0·25 and 20 % <i>ad val.</i>
Acid phosphate . . . . .	Per lb. 0·03
Ferro-manganese, ferro-silicon, spiegel, steel bloom ends, and crop ends of steel rails, for the manufacture of iron or steel . . . . .	Per ton 2·00
Lead, nitrate and acetate of, not ground . . . . .	5 % <i>ad val.</i>
Dry white and red lead, orange mineral and zinc white, or carbonate of zinc. . . . .	5 % <i>ad val.</i>
Colours, dry, not otherwise specified. . . . .	20 % <i>ad val.</i>
Paints and colours, pulped or ground in oil or other liquids, not otherwise specified. . . . .	30 % <i>ad val.</i>
Paints, ground or mixed in, or with, either japan, varnish, lacquers, liquid driers, collodion, oil finish, or oil varnish; rough stuff, fillers, and all liquid, prepared or ready-mixed paints, not otherwise specified, the weight of the package to be included in the weight for duty . . . . .	Per lb. 0·05 and 25 % <i>ad val.</i>
Oxides, ochres and ochrey earths, fire proof, umbers, and siennas, ground or unground, washed or unwashed, calcined or raw. . . . .	30 % <i>ad val.</i>
Paints and colours, ground in spirits, and all spirit varnishes and lacquers. . . . .	Per gall. 1·00
Paraffin wax, stearic acid, and stearin of all kinds . . . . .	Per lb. 0·03
Photographic dry plates . . . . .	Per sq. ft. 0·09
Albuminised paper chemically prepared for photographers' use. . . . .	25 % <i>ad val.</i>
Plumbago. . . . .	25 % <i>ad val.</i>
" all manufactures of, not otherwise specified . . . . .	30 % <i>ad val.</i>
Red and yellow prussiate of potash. . . . .	10 % <i>ad val.</i>
Castille soap, mottled or white, and white soap . . . . .	Per lb. 0·02
Soap powders, pumice, silver and mineral soaps, sapollo, and other similar articles, the weight of the package to be included in the weight for duty . . . . .	" 0·03
Spirituous or alcoholic liquors distilled from any material or containing or compounded from, or with distilled spirits of any kind and any mixture thereof with water—for every gallon thereof of any strength not exceeding the strength of proof. When of a greater strength than the strength of proof, at the same rate on the quantity there would be if reduced to the strength of proof, as follows, <i>viz.</i> :—	
(a.) Ethyl alcohol or the substance commonly known as alcohol, hydrated oxide of ethyl, or spirits of wine; gin of all kinds not otherwise specified; rum, whisky, and all spirituuous or alcoholic liquors not otherwise provided for. . . . .	Per gall. 1·75
(b.) Amyl alcohol or fusel oil, or any substance known as potato spirit or potato oil . . . . .	" 2·00

Classification of Articles.	Rates of Duty.
<b>Spirituans and alcoholic liquors, &amp;c.—<i>cont.</i></b>	<b>Dols. Cts.</b>
(c.) Methyl alcohol, wood alcohol, wood naphtha, pyroxylic spirit, or any substance known as wood spirit or methylated spirit; absinthe, arrack, or palm spirit, brandy, including artificial brandy and imitations of brandy; cordials and liqueurs of all kinds not otherwise specified; ginger wine, mescal, pulque, rum, shrub, schiedam, and other schnapps; tafia, angostura, and similar alcoholic bitters or beverages.....	Per gall. 2'00
(d.) Spirits and strong waters of any kind mixed with any ingredient or ingredients and being, or known, or designated, as anodynes, elixirs, essences, extracts, lotions, tinctures, or medicines not otherwise specified.....	2'00 and 30 % <i>ad val.</i>
(e.) Alcoholic perfumes and perfumed spirits, bay rum, cologne and lavender waters, hair, tooth, and skin washes and other toilet preparations containing spirits of any kind, when in bottles or flasks weighing not more than 4 oz. each	50 % <i>ad val.</i>
Do., do., in bottles, flasks, or other packages weighing more than 4 oz. each.	Per gall. 2'00 and 40 % <i>ad val.</i>
(f.) Nitrous ether, sweet spirits of nitre, and aromatic spirits of ammonia.....	Per gall. 2'00 and 30 % <i>ad val.</i>
(h.) In all cases where the strength of any of the foregoing articles cannot be correctly ascertained by the direct application of the hydrometer, it shall be ascertained by the distillation of a sample, or in such other manner as the Minister of Customs may direct.	
Starch, including farina, corn starch, or flour, and all preparations having the qualities of starch, not sweetened or flavoured.....	Per lb. 0'02
Do., sweetened or flavoured.....	" 0'04
Saccharin or any product containing over one-half of 1 per cent. thereof.....	" 10'00
Illuminating oils composed wholly or in part of the products of petroleum, coal, shale, or lignite, costing more than 30 cents per gallon	25 % <i>ad val.</i>
Sulphuric ether.....	Per lb. 0'05
Yeast cakes, compressed yeast and baking powders in packages of 1 lb. and over or in bulk.....	" 0'06

The following articles are free of duty:—

Alkanet root, crude, crushed or ground.	Extracts of logwood, fustic, and oak bark.
Aloes, ground or unground.	Foot-grease, being the refuse of cotton seed after the oil has been pressed out, but not when treated with alkalis.
Alum, in bulk only, ground or unground.	Gas coke (the product of gas works), when used in Canadian manufactures only.
Aluminium, or aluminium and alumina and chloride of aluminium or chloralum, sulphate of alumina, and alum cake.	Grease, rough, the refuse of animal fat, for the manufacture of soap only.
Aniline dyes and coal-tar dyes, in bulk or packages of not less than one pound weight, including alizarin and artificial alizarin.	Gums, viz.:—Amber, Arabic, Australian, copal, damar, kauri, mastic, sandarac, senegal, shellac; and white shellac, in gum or flake, for manufacturing purposes; and gum tragacanth, gum gedda, and gum barberry.
Aniline salts and arseniate of aniline.	Indigo auxiliary or zinc dust.
Antimony, not ground, pulverised or otherwise manufactured.	Kryolite or cryolite mineral.
Ashes, pot and pearl, in packages of not less than 25 lb. weight.	Litharge not ground.
Asphalt or asphaltum and bone pitch, crude only.	Mineralogical specimens.
Azeal or argols, crude only.	Oils, viz.:—Cocoanut and palm, in their natural state.
Beans, viz.:—Tonquin, vanilla, and nux vomica, crude only.	Otto or attar of roses and oil of roses.
Bismuth, metallic, in its natural state.	Pelts, raw.
Borax, ground or unground, in bulk only.	Pipe clay, unmanufactured.
Celluloid or xylonite in sheets, and in lumps, blocks, or balls in the rough.	Platinum wire; and retorts, pans, condensers, tubing and pipe made of platinum, when imported by manufacturers of sulphuric acid for use in their works in the manufacture or concentration of sulphuric acid.
Colours, metallic, viz.:—Oxides of cobalt, zinc, and tin, not otherwise specified.	

Rags of cotton, linen, jute, hemp, and woollen, paper waste or clippings, and waste of any kind except mineral waste.  
Resin or rosin in packages of not less than 100 lb.  
Roots, medicinal, viz.:—Aconite, calumba, ipecacuanha, sarsaparilla, squills, turaxacum, rhubarb, and valerian.  
Rubber, crude.  
Soda, sulphate of, crude, known as salt cake, for manufacturing purposes only.  
Soda ash, caustic soda in drums; silicate of soda in crystals only; bichromate of soda, nitrate of soda or cubic nitre, salsoda; sulphide of sodium, arseniate, binarseniate, chloride and stannate of soda for manufacturing purposes only.  
Sulphate of iron (copperas) and sulphate of copper (blue vitriol).  
Terra japonica or gambier.  
Ultramarine blue, dry or in pulp.  
Whiting or whitening, gilders' whiting, and Paris white.  
Camwood and sumac for dyeing or tanning purposes when not further manufactured than crushed or ground.  
Blood albumen, tannic acid, tartar emetic, and grey tartar, when imported by the manufacturers of cotton and woollen goods for use in their factories only.  
Chloride of potash in crystals, when imported for manufacturing purposes only.

#### INCREASE OF THE DUTY ON ALCOHOLIC MEDICINES, &c. IN INDIA.

By order of the Governor-General of British India, the following increase, taking effect from March 21st last, has been made in the duty on spirits (including alcoholic, perfumed, and medicinal preparations) imported into the country:—*A.* Spirit in a proportion to 20 per cent. and upwards, from five rupees to six rupees per imperial gallon or six quart bottles, of the strength of London proof. The duty to be increased or reduced in proportion as the strength of the spirit exceeds or is less than London proof. *B.* Perfumed spirit, in wood or in bottles, per imperial gallon or six quart bottles, from seven rupees eight annas to eight rupees. As the reason for the advance in the duty, it is stated that in some provinces the rates of duty on country spirit have been raised so high that, if any further increase were made, such spirit would be unfairly handicapped in comparison with foreign alcohol. It is the policy of the Government to impose as high a duty on country spirit as it will bear, and also to discourage the import of cheap and deleterious European spirit, which will be less able, it is thought, to bear the increased duty than the better grades of alcohol. The proposed increase of duty is estimated to add nine lakhs of rupees yearly to the revenue.—*Chemist and Druggist.*

#### EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

##### TURKEY IN ASIA.

##### Mines and Minerals in Trebizond.

Like all other parts of Asia Minor, the vilayet of Trebizond is very rich in minerals, and, as in all other parts of the Turkish Empire, these resources are almost entirely neglected. In the mountain ranges that traverse the southern part of the province there are some 120 known mineral deposits. The more important of these are distributed as follows:—In the sandjak of Trebizond, 21 mines of argentiferous lead, 34 of copper, 3 of lead and copper, 2 of manganese, 10 of iron, and 2 of coal; in the sandjak of Samsoon, 1 of argentiferous lead and 1 of manganese; in the sandjak of Gernushhané, 37 of argentiferous lead, 6 of copper.

None of these deposits are worked to any advantage. The lack of enterprise, difficulties of transportation, and restrictions imposed by the Government, prevent the development of these resources which might, under proper management, add so much to the wealth of the country. There is an abundance of wood, as well as the two undeveloped coal deposits referred to, for working the ores, so that the failure to develop these resources seems the more inexcusable.—*United States Consular Reports.*

## GUATEMALA.

*Matches.*

Under date of October 15th, 1889, Consul-General Hosmer reports that, although of comparatively insignificant consideration, the manufacture and supply of phosphorus matches is an important branch of modern industry and of general use among all classes of society in the civilised world. Guatemala imports annually 115,000 gross of wooden safety matches of Swedish, Danish, and German manufacture. These sell in this market for from 1·37½ dols. to 1·50 dols. per gross in Guatemalan currency, that is, about 98 cents to 1·07 dols. in United States gold. Belgium also contributes to the supply, and a small quantity is imported from the United States. These latter are of a better quality, are of coloured woods, and sell at a higher price. There are, in addition to these wooden matches, 15,000 gross of wax imported, chiefly from Italy, into Guatemala. The duty paid on the importation of matches is 4½ cents per gross on the average weight of cases of 50 gross each.

*Mica.*

Consul-General Hosmer, under date of December 6th, 1889, reports that large beds of mica are to be found in the Republic of Guatemala at 15 leagues distant from Guatemala City, the capital. They are said to extend some two or three miles of continuous length, and are capable of being cut into elastic plates of extreme thinness, excellent for commercial purpose.

There being no occasion for the use of stoves in this climate to obtain artificial warmth, and the cooking being done either upon a primitive arrangement for burning charcoal or in ranges built of bricks and adobe, the employment of mica for home consumption is rendered unnecessary, and therefore the beds of mica have been as yet untouched.

Reports upon this mineral in North Carolina show that the article in question is worth 450 dols. per ton, and that its refuse is good as a fertiliser. Such being the fact, the small cost for the labour of obtaining it in this country should make the quarrying and cutting of mica a most profitable undertaking as a matter of export. Access to the mica beds referred to is by a good cart road for some six leagues and the rest of the distance by mule-path.

*Rubber.*

Under date of October 11th, 1889, Consul-General Hosmer reports that the export of rubber from the Republic of Guatemala to the United States during the year ended June 30th, 1889, amounted to the sum of 64,170·59 dols., and the average price was 50 cents per lb. This quantity is likely to be increased in the future, owing to the stringent law enacted, and being more strictly enforced by the Government for the protection of the rubber-tree from a bleeding process to which it had been subjected by careless natives, and the probability of planting on the part of intended colonists. Inasmuch, however, as from 15 to 20 years are required to obtain a profitable result from planting the rubber-tree, it would not hold out a favourable inducement to the agriculturist, unless planted in connexion with the banana-tree, the fruit of which could be disposed of on a paying basis until the rubber reached the point of profitable production.—*Ibid.*

## TRINIDAD.

*Asphaltum.*

Under date of November 10th, 1889, Consul Sawyer reports that the shipments of asphaltum from Trinidad—the greater part to the United States—from January 1st to June 30th, 1889, amounted to 32,460 tons, being a prodigious increase over any previous semi-annual shipments during the history of the colony.—*Ibid.*

## MEXICO.

*Cinnabar in Sonora.*

Under date of September 10th, 1889, Consul Willard, of Guaymas, reports that within the past six months a deposit of cinnabar (quicksilver ore) was discovered in his consular district (Sonora), about 150 miles from Guaymas, in the Ures district. The deposits are being worked, and are reported to be extensive—one yielding 30 per cent., while as high as 50 per cent. has been found. Twenty flasks of quicksilver have been extracted. The owners of the five claims or mines located are developing their grounds with the object of proving their value. This is the first cinnabar located and worked in Sonora.—*Ibid.*

## RUSSIA.

*Chemical Industry in Odessa.*

The manufacturing chemical industry in Odessa is a growing and prosperous one. It now embraces the manufacture of acids, sulphates, oils from exotic seeds, glycerin, and soaps. The principal customers for the Odessa soap are found in the immediate neighbourhood of Odessa, throughout Southern Russia, the Crimea, the Caucasus, and the Black Sea littoral. A little goes to Turkey, and twice yearly Russian steamers take out from 10,000 to 12,000 poods of washing soap, small quantities of toilet soap, engine grease, and caustic soda to Wladiwostok, in Siberia. Business, however, is much impeded by the continual variations in the price of the rouble, which affects specially all transactions with foreign countries.

*Soap-making.*

The raw material used here for soap-making is principally mutton tallow, but the price of tallow is steadily advancing, owing partly to the decadence of sheep-farming in Southern Russia and to the increased local outlet for tallow in the manufacture of butterine and stearin candles, and the soap-makers are therefore beginning to fall back upon cocoa-nut and palm oils.

The attempt has also been made to introduce Australian tallow. Oils are all purchased through London, and a Swiss firm also competes. Marseilles oil firms are also endeavouring to gain a footing, but their success is limited, as the Marseilles oils, though cheaper, are much inferior to Ceylon cocoa-nut oil in quality.

*Caustic Soda.*

The consumption of caustic soda amounts to about 9,000 drums (1,800 tons) yearly. All this is of British manufacture, and is exclusive of the enormous quantities going direct to the Russian petroleum fields. The caustic soda used here is from 70° to 74° in strength, recently 76 and 77 per cent.

*Soda Ash.*

Soda has also been introduced. Since 1887 a large number of soapworks have been erected here, who now manufacture soda crystals as a by-product, and are superseding the English crystals, which used to be taken here. Soda ash also was formerly bought in England, but this has all ceased now.—*Chemist and Druggist.*

## SPANISH POSSESSIONS.

*Drugs for Cuba.*

Trade returns are not compiled very quickly in Spanish America, and so it is that we are only now in possession of the commercial statistics for Cuba of 1887. In that year 70,852 kilos. of pharmaceutical products were imported into the island against only 10,525 kilos. in 1886; the imports of soap were 423,658 against 534,257 kilos.; and of chemicals 72,988 against 75,367.

*Mineral Waters.*

There is a large demand in Cuba for mineral waters, especially Vichy water.

*Perfumery.*

The consumption of fine perfumery is growing every year, and France (according to her Consul) in this department comes first, with the rest nowhere. Some French firms find it a good plan to send over boxes of assorted bottles of scents, which have a particularly rapid sale. The imports in 1887 were 12,325 kilos, against 4,783 kilos, in 1886. Until quite recently the British manufacturing perfumers did not compete on the Cuban markets, but now English samples are beginning to be shown in pharmacies and bazaars.—*Ibid.*

## TURKEY IN ASIA.

*Drugs for Smyrna.*

The principal pharmacies of Smyrna are owned by British subjects, and it is, therefore, but natural that the greater part of the medicines consumed should come from England. Certain specialties, such as antipyrin and quinine preparations, however, are brought from Höchst and Stuttgart, in Germany. So-called house medicines are very largely bought in Paris, because the manufacturers pay great attention to neat and tasteful packing, and the population here are now quite accustomed to these neat preparations. The use of raw drugs is very great in Smyrna, and this is explained to some extent by the habits of the natives, who in illness prefer to make up their own remedies from the raw material. The wholesale drug and spice business is in the hands of a few very well established firms, who purchase in London, Marseilles, Stuttgart, and Trieste. The principal drugs consumed in this place are camphor, saffron, manna, coriander, star-anise, balsams, alum, rhubarb, jalap, sarsa, castor oil, tamarinds, pimento, and nutmegs.

*Soap.*

The finer toilet soaps and perfumery are drawn from France and sometimes also from Southern Germany. A very cheap soap, in 1-kilo. bars, selling here at 10s. per cwt., is imported from England, and is exceedingly popular.

*Chemicals in Smyrna.*

Potash is the largest article of consumption among the heavy chemicals, about 3,000 2-cwt. casks being consumed annually. The principal use of the article is for drying raisins, for which purpose it is dissolved and mixed with a little oil. Formerly, the potash came *via* Trieste, and this variety was much liked, but the Austrian railways raised their tariff to such a rate that Cologne has quite usurped the potash trade. Caustic soda (40 to 45 per cent.), for soap-making, is bought exclusively in England, about 8,000 casks a year, and the small quantity of carbonate of soda used here is made by the Solvay and Leblanc works in Northern France, and exported *via* Antwerp.—*Ibid.*

## MISCELLANEOUS TRADE NOTICES.

## BRITISH TRADE IN SERBIA.

The Skupstschina has passed the final reading of a Bill for granting a monopoly of the petroleum and other oil resources of the kingdom to a syndicate of London financiers. The monopoly is for 15 years, and in order to encourage the concessionnaires the Government have granted them immunity from import and export duties for 10 years, and from internal taxes for eight years. In political circles here this concession is regarded as the most important departure in commercial policy which has been taken by the Government for a very long time. Hitherto Serbian trade has depended entirely on Austrian markets; but since the opening of the Salonica railway an opportunity has been afforded the Serbian merchants of exporting direct to their foreign clients. It is hoped that the new concession may be the means of opening relations with English markets.—*Daily Graphic.*

## PROSPECTS OF THE IRON ORE SUPPLY.

The importation of iron ore into the United States shows remarkable fluctuations, which are not to be accounted for entirely by variations in the demand in this country or the condition of its iron business, but must, to some extent, be due to fluctuations in cost of mining and in the demand for ore in other countries than our own. Here are the figures:—

## IMPORTS OF ORE DURING THE FISCAL YEARS, ENDING JUNE 30.

Imported from	1885.	1886.	1887.	1888.	1889.
France and African Mediterranean ports	25,360	107,366	215,760	163,496	78,137
Italy .....	16,213	20,982	114,123	98,343	66,812
England .....	11,890	15,033	72,546	56,090	29,216
Canada .....	17,860	7,906	18,430	13,380	9,284
Greece .....	..	7,700	44,173	25,707	13,181
Spain .....	213,906	128,586	522,719	416,138	190,460
Cuba .....	28,209	51,268	109,928	117,504	225,525
Total all countries ..	425,870	701,243	1,141,774	919,614	652,032

The decline in imports during the last three years in the face of a greatly increased production of pig iron indicates that our iron mines are more than keeping pace with our blast furnaces in increase of production. Cuba is now the largest source of our foreign supply, and Spain has taken a second place. The mines in Cuba were opened only a few years ago by an American company, and they might almost be considered part of our domestic supply, as is also that from the American-owned Canadian mines. Leaving out the importation from Cuba, the total of foreign ores imported is less than 4 per cent. of our domestic production. The increasing cost of ore in Spain and other European countries indicates the probable cessation altogether of our importations from these sources, and will leave us dependent upon our own country, Cuba, and Canada. Fortunately in these countries, our near neighbours, as well as at home, there is a constant increase in the development of iron mines, and no prospect of any scarcity in either source for a long time to come.—*Engineering and Mining Journal.*

## THE TRADE OF BRITISH INDIA.

*Cinchona Bark.*

The quantity of cinchona bark exported rose from 1,286,900 lb. in 1886–87 to 1,449,313 lb. in 1887–88, and to 3,074,090 lb. in the following year. This expansion was accompanied by a largely reduced value, the result of a fall in prices which has been so heavy that cinchona has been sold below the cost of production. Production in fact has outrun consumption for the time being. Nearly the whole of the export is from Madras, the bark produced in Bengal (at least in the Government plantations) being manufactured there for consumption in India. It is now made into sulphate of quinine at a cost which is not higher than that of the imported drug, low as that is.

*Quinine.*

The very low price to which quinine has fallen has greatly stimulated its import. The fall in price has enabled quinine to more than resume its place in India, and has, for the time, slightly restricted the use of alkaloids made in the country.

*Oils.*

The importation of mineral oils has progressed in the following manner during recent years:—1883–84, 13,883,838 galls.; 1884–85, 27,306,999 galls.; 1885–86, 21,311,942 galls.; 1886–87, 31,949,633 galls.; 1887–88, 31,421,559 galls.; 1888–89, 39,951,885 galls.

Thus, the quantity imported last year was almost three times as large as the imports of six years ago. The use of mineral oil as an illuminant is now quite common in India, and is, indeed, in urban tracts, the rule rather than the exception.

These large importations of mineral oil have affected the domestic economy of the natives in two ways: the oil has displaced vegetable oils, and the tinned iron cans in which the import is made have displaced the earthen jar and the brass pot to a large extent. An importation of 30 or 40 million gallons of oil means also an importation of from six to eight million cans of 5 gallons each. These millions of cans were for some considerable time cut up by tinplate workers for the manufacture of other articles, but now they are also commonly used to hold and convey grain and other stores, water and other liquids, and they are amongst the most common objects in an Indian bazaar. They are also used as building materials in the repairs of roofs.

Russian oil, the importation of which commenced only three years ago, and which is said to be on the whole not quite equal to American oil in quality, but is appreciably cheaper, is competing with remarkable activity with American oil, as will be seen from the following figures:—

	From United States.	From Russia.
	Gallons.	Gallons.
1883—84 .....	12,715,837	..
1884—85 .....	26,026,608	..
1885—86 .....	20,229,350	..
1886—87 .....	20,141,942	1,577,392

1888—89 .....	20,653,975	17,516,003

—Board of Trade Journal.

#### PRODUCTION OF BAKU DISTILLERIES IN 1889.

The *Moniteur Officiel du Commerce* for the 27th March, quoting from *La Russie Commerciale*, gives the following statistics of the production of naphtha in the distilleries of Baku during the year 1889:—

The distilleries have received during the year a quantity amounting to 186,220,470 poods.

The consignments have been:—To foreign countries, 41,848,295 poods of naphtha product, of which 32,758,231 poods were distilled petroleum; to the home markets, 114,079,935 poods of naphtha products, of which 23,361,881 poods were distilled petroleum and 75,219,854 poods residues of naphtha; to Transcaaspia, 9,612,943 poods, 1,587,257 poods of which were naphtha residues.—*Ibid.*

#### THE EXPORTATION OF SALT FROM THE MERSEY.

The exports of salt to foreign countries from Liverpool during April amounted to 59,537 tons, against 48,536 tons during April last year, an increase of 11,001 tons. The shipments during the first five or six months of last year were equal to the average of previous years, the quantity being assisted very much by the balances of contracts at cheap prices. As the total output for the first three months of this year exceeded the output of the same period of last year, the maintenance of the foreign exports at a good average must be very reassuring to those interested in the salt trade, and who believed our English production of the article would be taken as usual abroad at prices that must leave good profits to the producers.—*Chem. Trade Journal.*

#### NITRIFICATION IN CAVES.

Caves containing deposits of earth with from 4 to 30 per cent. of calcium nitrate, and 5 to 60 per cent. of calcium phosphate, says the *American Druggist*, are common in Venezuela, not only in the littoral mountain chains, but also on the flanks of the Cordillera of the Andes. In

these deposits are imbedded remains of mammalian bones, preserving their form, but so friable as to fall to powder when they are extracted. They consist solely of calcium phosphate; the gelatin has been nitrified and dissolved out, and the calcium carbonate of the bones has been used up in neutralising the nitric acid produced. The nitric ferment is found in abundance throughout the deposits in a very well developed form. Some of these deposits are 10 metres thick.—*Ibid.*

#### CHEMICALS EXPORTED FROM THE TYNE.

The quantity of chemicals exported from the Tyne during last month shows a slight decrease in the total tonnage, as compared with the corresponding month of last year. The figures are as follow:—

	1889.	1890.
	Tons.	Tons.
Alkali and soda ash .....	1,590	1,175
Bicarbonate of soda .....	8	10
Bleaching powder .....	2,035	3,278
Manure .....	815	579
Soda crystals .....	2,482	2,701
Sulphate of soda .....	6	87
Other chemicals .....	2,877	1,957
Total tons .....	9,813	9,487

#### SUMMARY OF THE MINERAL PRODUCTION OF CANADA OF 1889.

We are indebted to the courtesy of Mr. Alfred R. C. Selwyn, Director of the Geological and Natural History Survey of Canada, for the preliminary statistical table of the mineral production of Canada for 1889. This is not the final statement, the returns not being quite complete, and is, therefore, subject to revision.

Name of Product.	Quantity (a).	Value (b).
Antimony .....	Tons 55	Dollars. 1,100
Asbestos .....	" 6,014	424,350
*Bricks .....	Thousands 190,724	1,252,667

Gold (e) .....	Oz. 61,739	1,116,145

\* Some returns yet to be received.

(a.) Quantity marketed, except when otherwise specified. The tons are of 2,000 lb.

(b.) Market value; less charges of transport from point of production.

(c.) Oven coke; all the production of N. S.

(d.) Copper contents of Canadian ores at 13 cents per lb. at the mine.

(e.) Nova Scotia gold is calculated at 19.50 dols. per oz., and that from British Columbia at 17.00 dols.

SUMMARY OF MINERAL PRODUCTION OF CANADA—*cont.*

(*f*) Production of New Brunswick and Ontario, plus Nova Scotia exports.

(*g*) New Brunswick production, plus Nova Scotia exports.

(*h*) These figures are calculated from the inspection returns at 100 galls crude for 38 galls refined oil, and are computed at 954 cents per barrel of 35 imp. galls. The barrel of refined oil inspected was assumed to be 42 imp. galls.

—*Engineering and Mining Journal.*

## THE REGULATION OF THE SALE OF FERTILISERS IN GERMANY.

Under the liberal Government which France has chosen for itself, it has been thought necessary to enact special laws regulating the sale of manures.

In antioctate Germany the State has not yet turned its attention to this question, and it is through the private action of the individuals interested—both buyers and sellers—that proposals have been made for the regulation of transactions in fertilising materials.

The antithesis is sufficiently striking to give interest to some details as to the resolutions adopted by a committee composed of merchants and agriculturists.

In the United States, in France, and in Belgium, says the *Deutsche Landwirthschaftliche Presse*, from which we borrow these remarks, abuses have given rise to legislation against the delinquents.

In Germany, where there is just as much to complain of, it is beginning to be thought necessary to protect those who are the victims, but it is wished to effect this without having recourse to State intervention. It would be grand, worthy of the German spirit, said M. Schultz, to attain the end desired by a common effort, originated by the private action of manufacturers, merchants, agriculturists, and representatives of science, associated together with the view of putting the trade in fertilising materials on a secure footing throughout Germany. To succeed in such a movement, and by means independent of the public authorities, this would be a good honour for the industry and trade in fertilising materials for German scientific men in particular, for the Society of Agriculture, and, moreover, adds he, for the German nation, and for the lofty and noble spirit which animates it.

The enthusiastic appeal of M. Schultz has not fallen unheeded upon his country. The section dealing with the subject at the Magdeburg meeting appointed a special committee upon it, consisting of nine delegates, three representing agriculture, three the manufacturing interest, and three the agricultural stations. Meeting at Berlin on the 15th October last, under the presidency of Dr. Maercker, the eminent professor at Halle, this committee has decided upon the following recommendations:—

It is necessary that all sacks containing commercial fertilisers offered for sale should bear upon them in printed characters the exact designation of the manufacturer, the name of the fertiliser, and the amount and nature of valuable substances contained in it. It is also desirable that the sacks should always be of uniform weight, which might be fixed at 50, 75, or 100 kilos.; the sacks should be completely filled.

As regards the name and composition of the fertiliser, the sub-committee has arrived at the following conclusions:—

In the case of *superphosphate*, without any qualification, the amount of soluble phosphoric acid should be indicated.

When the *superphosphate* contains phosphoric acid partly soluble in water and partly insoluble, the value of which must therefore be expressed, the quantity of each of these two forms of phosphoric acid ought to be stated on the sack.

Sacks of *precipitate* should bear a statement of the total phosphoric acid, and those of *finely powdered Thomas-slag*, both of phosphoric acid and fine dust.

Sacks of *bone meal*, *fish guano*, *meat dust*, *Peru guano*, *wool dust*, &c., ought to be labelled with their contents of phosphoric acid and of nitrogen.

*Ammoniacal superphosphate*, obtained from *superphosphate* and pure ammonium sulphate, should tell the amount of soluble phosphoric acid and of nitrogen.

In the case of mixtures of *nitrogenous substances with superphosphate*, i.e., *superphosphate*, associated with organic nitrogenous matter (except leather, dust, wool, &c.), the amount of total nitrogen, and approximately the proportion of organic matter to ammoniacal nitrogen should be stated.

*Nitro superphosphates*, mixtures of *superphosphates* with Chili nitrate, should be marked with the amounts of nitrogen and soluble phosphoric acid.

Mixtures of *nitrate of soda*, *sulphate of ammonia*, and *superphosphate* should be labelled with their percentage of phosphoric acid, soluble in water, nitrate, and ammoniacal nitrogen.

*Dried blood*, *bone* and other *nitrogenous manures* should have their names and percentage of nitrogen indicated. In all mixtures of potash salts, there should be stated the percentage of potash together with that of all other valuable substances present. It would be well to arrange with the firms concerned to give the percentage of potash in kainite and other potash salts instead of, as at present, the amount of sulphate of potash contained in them.

The sampling should take place immediately upon receipt of the goods, and should be done in the presence of an agent of the seller or some impartial and competent person.

The sub-committee of the 15th October has decided to put these measures into practice until the autumn of 1890. It has also expressed a desire to see a uniform method of examining manures adopted, and has given it to be understood that a conference of delegates from the experimental

stations, with representatives of the manufacturers, would not only contribute towards this result, but also clear up the different questions raised on this subject.

Such are the commercial regulations which the German Society of Agriculture has just adopted, with the hope of ensuring integrity in the manure trade and thus rendering it more active. Small dealers will be the first to profit by them; small farmers, so often exposed to fraud against which they are unable to defend themselves, will regain confidence, and an excellent effect will shortly be produced on the progress of agriculture.—*Chem. Trade Journal*.

#### THE PHOSPHATE BEDS OF FLORIDA.

A. R. Ledoux. *Engin. and Mining J.* **49**, 175—177.

The phosphate beds occur in the marls of the Eocene and Miocene, which extend along the Atlantic coast from New Jersey to Florida. Associated with the phosphate nodules, which vary in size from a pea to masses of occasionally 100 lb. are the bones of fishes, the teeth of great sharks, the fossil horse, elephant, &c., representing many geological ages.

The phosphate deposits in South Carolina have been worked for some years, and the companies owning these deposits are said to have mined 423,720 tons in 1889. Up to last fall the river nodules were all that were known of the Florida phosphate beds and attracted comparatively little attention. A white subsoil containing 80 per cent. of phosphate of lime was then discovered, and the extent of these beds has not yet been ascertained. They lie in lenticular beds upon the limestone, and are covered by sandy soil and clay subsoil, rarely cropping out at the surface. The phosphate is found at varying depths below the surface from 2 to 10 or 12 ft. down. When wet it is dark or light yellow, but usually a dazzling white when dry. Some of the deposits are over 16 ft. thick. In the neighbourhood of Dunellen it has been estimated that 3,000 acres are underlaid with the mineral, averaging 55—60 per cent. of phosphate of lime.—J. B. C.

#### A NEW GUM.

E. Sickenberger. *Chem. Zeit.* **14**, 350.

For some time past large quantities of a gum have been sent from Bushir, on the Persian Gulf, to the small ports on the west coast of the Red Sea, for the purpose of mixing with the Kordofan Hashabi-gum. From thence the mixture is sent to Assonan, packed in old Kordofan gum cases, and sold as the best Hashabi-gum. This new gum closely resembles the best Hashabi-gum in appearance, but it is insoluble in water, in which it only swells up. According to the author it is probably a variety of the "Persian gum" of the Indian market, derived from various species of *Prunus*, perhaps from *Prunus Bokharensis* Royle and *P. Puddum Roxburgh*. It is probable that if its sale in the local market (Cairo) be stopped, other channels for its dissemination as "gum arabic" will be sought for.—H. T. P.

#### THE MEAN COMMERCIAL VALUE OF GERMAN PATENTS.

*Chem. Zeit.* **14**, 303.

It is well known that holders of German patents are confronted at the beginning of each year by the question, whether the protection granted to them is still worth the patent fees again falling due. As shown by the Patent Office, this fact renders it possible to calculate for each year the average value placed upon German patents by their holders. If the total patent fees for any one year =  $P$  marks, and the number of patents in force at the end of that year =  $n$ , then the average fee paid for each patent =  $p = \frac{P}{n}$ . Now it is perfectly admissible to consider these annual patent fees paid by patent holders as the interest on a certain capital. Assuming this interest to be at the rate of 4 per cent. the average market value of a German patent would be  $w = 25 p = 25 \frac{P}{n}$  marks.

By means of this simple calculation the following results are obtained for the last 12 years of the existence of the German Patent Office:—

Year.	Patent Fees, P Marks.	Number of Patents in Force, n	Average Annual Fee, $p = \frac{P}{n}$ Marks.	Capital Value of a Patent $w = 25 p$ Marks.
1878	265,150	4,227	62.73	1,568
1879	410,165	6,807	60.26	1,507
1880	514,525	8,007	64.26	1,607
1881	660,940	8,619	76.68	1,917
1882	787,850	9,452	83.36	2,083
1883	928,570	10,535	88.14	2,204
1884	1,058,610	10,994	96.29	2,407
1885	1,157,210	11,046	104.76	2,619
1886	1,274,940	11,249	113.34	2,834
1887	1,375,950	11,512	119.52	2,988
1888	1,472,050	11,810	124.64	3,116
1889	1,637,840	12,732	128.64	3,216

—H. T. P.

#### COMMUNICATIONS ON SEVERAL IMPORTANT DRUGS AND CHEMICALS.

*Chem. Ind.* **13**, 29—31.

*Hypnotics*.—This class has become augmented by the addition of chloralamide and somnal, but these are still only in the experimental stage. It may be noted that favourable opinions at first entertained as to the therapeutic value of new products may soon become discredited and the substances themselves relegated to obscurity.

*Iodine*.—After remaining at a selling price of 9d. per oz. for two years, it came down as low as 4d. on the 12th of August, but on the 2nd of September the price rose again to 9d. These fluctuations arose from the operations of a syndicate, but the instability of price depends largely on the uncertainty as to the extent to which the residues in the South American nitre factories may be worked up, together with the very varying requirements of the public consumption.

*Copper*.—Large transactions have lately been effected and the price had fallen from 80l. to 36l. per ton after the failure of the Société des Metaux à Paris, but has since risen to 50l. Although consumption has increased in electrical, ship building, and machinery work, it is still insufficient to account for the present high prices in view of the fact that stocks have not suffered any reduction, in fact supplies greatly exceed deliveries.

*Olive Oil*.—It was feared that much harm had been done to the fruit by worms, but the aspect of the present harvest is reassuring. It appears that such olives as were attacked by worms fell to the ground in due course, leaving the untouched olives on the trees, which have yielded an oil of excellent quality. Continuously favourable weather has resulted in imparting to the oil an exceptionally fine mild flavour, devoid of the bitterness frequently complained of. The quantity of the South Italian harvest is believed to be not much less than that of last year, but the harvest in the South of France and the Riviera has been so small as to give reason for fear that the yield will be augmented by admixture with other oils.

*Opium*.—Although the opium harvest of last year turned out to be smaller than was expected, and unfavourable reports on the condition of the new plants have come to hand, the condition of the market has remained on the whole unaffected. It appears that the consumption of Turkish opium has diminished whilst the inquiry for Persian opium has increased. The importation of foreign opium

into China has decreased in consequence of the increase in the home-grown article. Chinese opium is inferior in quality to the Indian, but is preferred for smoking as the narcotic constituents are not so quickly extracted on burning. The spread of opium-smoking in China may be seen from the fact that the Chinese production amounts to 225,000 piculs, and the imports of Indian opium amount to 75,000 piculs, whilst the yearly consumption of an accustomed smoker amounts only to one-twentieth of a picul.

**Oxalic Acid.**—The combination between the German and English manufacturers which had been kept up for several years came to an end in 1889, and considerable reduction in the price of oxalic acid and salts of sorrel may be expected. Already offers have been made by English manufacturers for delivery in this year at 30 per cent. below the present prices.

**Phosphorus.**—In consequence of the increasing French and Russian competition, the quotations for English phosphorus have been lowered occasionally during the year, but German consumption has been considerably assisted by importation from England.

**Quicksilver.**—The increasing consumption of quicksilver by the newly-established gold mines has augmented the value of this metal considerably, but the market has not been subject to the disconcerting fluctuations notable in former years. A diminishing value may, however, be looked for, as the Spanish and Russian production will probably be increased.

**Shellac.**—Shipments from Calcutta have experienced a very considerable decrease in the last year, and the increase in price would have probably been greater if the stocks in London had not been so large. The price for prime orange shellac is now 110s. per cwt., and for seconds, 75s., whilst the same qualities obtained only 65s. and 40s. per cwt. respectively in the year before.

**Sulphonal.**—Competition has reduced the price of this article to something near the limit of profitable production. The new substances named Trional and Tetronal, which stand in close relation to sulphonal, have not yet been manufactured on the large scale.

**Vanilla.**—The harvest of vanilla pods has proved inferior both in quantity and quality. This year's yield from Bourbon, Mauritius, and the Seychelles amounts to 60,000 kilos., against 80,000 kilos. in 1888 and 158,000 kilos. in 1887. As the world's needs in this article is estimated at 10,000 kilos. per annum, an increased price must be expected.—G. H. B.

#### THE FATALITIES AT THE LEEDS FORGE.

The report of Dr. Stevenson, who, at the request of the Home Secretary, attended the inquest in November last on the bodies of two men who met their death by water-gas poisoning at the Leeds Forge, has been issued. He states that it is now nearly half a century since Leblanc first announced the poisonous character of carbonic oxide gas, which is the poisonous constituent of a great number of mixed and commercial gases, such as charcoal vapours or fumes, the vapour of burning coke, the combustible gases from blast-furnaces, producer gas, forge gas, gas from regenerator furnaces, gas leaking from stove pipes, and the so-called water-gas. After describing the manufacture of water-gas, Dr. Stevenson says that it consists approximately of 40 per cent. by volume of carbonic oxide and 50 per cent. of hydrogen, the remainder being diluent gases. It is practically odourless, hence leakages of the gas cannot be detected by the sense of smell. He goes on to state that in the eight years ending 1887 the fatal cases of water-gas poisoning in the four American cities of New York, Boston, Baltimore, and Chicago, were 295. The manufacture of water-gas had, it was stated, been prohibited in the States of New Jersey and Massachusetts and in Paris. The alleged odourisation at the Leeds Forge was ineffectual. "It must be borne in mind," says Dr. Stevenson, "that safety is conferred not by simply imparting a decided and unmistakable odour to the gas, but by rendering it so far odorous that it is readily detected by smell when mixed

with at least 5,000 volumes of air. Anything short of this confers only fancied safety, so poisonous is carbonic oxide gas." In dealing with the Leeds case he simply gives a detailed account of the accident and the sensations experienced by the medical men at the *post mortem* examination, and then the inquest.—*Chem. Trade Journal*.

#### NOVA SCOTIA MINES.

The report of Mr. Edwin Gilpin, jun., Inspector of Mines for Nova Scotia, for the calendar year 1889, is issued with a relative promptitude commendable in view of the tardiness which characterises many Government statistical reports. Those of the United States, it may be remarked in passing, while not so prompt as would be desirable, are nevertheless published with more punctuality than the similar reports of several European countries. From the Nova Scotia report we abstract the following principal statistics and remarks:—

#### Total Production.

The summary of the principal mineral products for 1888 and 1889 is:—

	1888.	1889.
Gold .....	oz. 22,407	26,155
Iron ore .....	Tons 41,611	45,907
Manganese ore .....	" 88	67
Coal raised .....	" 1,776,128	1,756,279
Coke made .....	" 29,808	35,505
Gypsum exported.....	" 125,800	147,344
Barytes .....	" 1,100	None
Grindstones, &c.....	Value \$17,225	\$18,000
Moulding sand exported .....	Tons 169	179
Antimony ore exported .....	" 508	55
Limestone.....	" 15,448	19,000
Copper ore .....	" ..	500

It is to be regretted that there is no uniform system of stating quantities and values. The tons of coal and coke are stated as tons of 2,240 lb., from which the inference would be that the other tons quoted are short tons of 2,000 lb. The more important substances, with the exception of coal, show an increased output in 1889 over that of the preceding year.

#### Coal.

The total sales in 1889 were 1,555,107 tons, a slight falling off from 1888. Of these the United States took 29,986, about the same as in 1888. The remainder was sold in Quebec, Nova Scotia, New Brunswick, Newfoundland, and Prince Edward Island. Sixteen accidents in Pictou county were reported, of which two were fatal. Some trouble was caused by gas, but the system of inspection appears to be good. In Cape Breton county there were 10 accidents, of which five were fatal; one explosion of gas is reported. Close attention is being given to improved safety devices, better cables, ventilation, and prevention of fires. Under provisions of an enactment of the previous year, a number of instructors for miners' schools were appointed.

#### Gold.

The number of mines reported was 33; the mills (50) crushed 39,160 tons, an average yield of 17 dwt., 22 gr. The average earnings per man are figured at 2·22 dols. per day, or 666 dols. per year of 300 working days, not at all a bad showing. From 1862 to and including 1889 the total yield of the province has been 482,316 oz. At 18 dols. per

oz., which appears to be the average for Nova Scotia gold, this represents a total value of 8,681,688 dols. for the 21 years.

#### *Other Mineral Products.*

The greater part of the iron ore output was from London-derry. New discoveries of iron ore are reported on the East River in Pietou and at Brookfield, Colchester. The Loch Lomond manganese ore is sold on a guarantee of 90 per cent. peroxide. The barytes mines were closed during 1889. Some prospecting for lead was done in Colchester County. The small copper ore product is ascribed to the break in price of the metal.—*Engineering and Mining Journal*.

#### EXHIBITION OF APPLIANCES IN BERLIN IN RELATION TO CHEMICAL INDUSTRY.

The Exhibition was promoted for the display of methods and appliances having for their object the minimising of risk to life or limb where the circumstances include the element of danger. The author has limited his article to a notice of those means which can be employed for the protection of workers in the chemical industries, but the number of these is too large to admit of more than a general reference here. The noticed are arranged under several heads.

#### *Transport of Corrosive Liquids.*

For drawing off the contents of carboys, a rubber cap fitting over the neck is provided with bent glass tubes and a force pump, the arrangement working like that of an ordinary wash-bottle. For preventing the spirting of liquid in emptying a carboy, a rubber nose-piece having a vent hole is fitted on the neck. Instead of the usual straw packing it is proposed to surround the carboy with infusorial earth which would absorb the corrosive liquid in case of fracture, the packing being easily regenerated after an accident by washing and drying. An automatic arrangement for controlling the admission of compressed air to a montejus is described.

#### *Mineral Water Manufacture.*

All the exhibits in this department involve the use of liquid carbonic acid which avoids many of the dangers incidental to the preparation of the gas itself. The safety arrangements comprise separate expansion vessels, pressure gauges, safety-valves, and automatic pressure-reducing valves. As a provision against possible fracture of the iron cylinder containing liquid carbonic acid, it is enclosed in a strong case of iron trellis work.

#### *Varnish and Pitch Manufacture.*

To minimise the chance of firing in case the liquid should boil over the sides of the vessel, the furnace is separated from the boiling house by fire-proof walls. Vessels for boiling linseed oil are movable on wheels along a line of rails, so as to afford easy removal when necessary. Foul smelling vapours are drawn by a draught through a coke fire.

#### *Soap Manufacture.*

To avoid the dangers incidental to shallow boiling vessels, the rendering copper is made deep and is surmounted by a hood.

#### *Lampblack Manufacture.*

An automatic apparatus for the deposition and collection of lampblack in a closed chamber provided with windows for observing the progress of the operation. A vertical revolving shaft carries plates cooled with water, on which the lampblack accumulates, the deposits being removed and delivered into receptacles by scrapers.

#### *Match Manufacture.*

Dipping machines for pointing the matches with igniting composition are made to work automatically and in a closed chamber, by which all danger to the workmen from phosphorus fumes is avoided.

#### *Glue Manufacture and the Grinding of Bones and Slag.*

The bleaching of glue with sulphurous acid and the subsequent drying of it are carried out in a closed chamber through which a current of air is maintained, carrying the sulphurous acid and moisture to a chimney. This method is applied to the grinding and treatment of bones, mineral phosphates, and Thomas slag, where injurious dust and acid vapours are given off. Roller mills are closed in by curtains or boxes, and the dust is conveyed by a draught of air to a chamber containing baffling arrangements to cause the deposition of the dust. The ground material is sifted as it comes from the mill, and the coarser particles are returned automatically to the mill, thus confining the grinding practically to one operation. Some of the mills consist of revolving drums of metal containing steel balls. Draughts of air are used to remove foul smells from raw bones, and the vapours evolved in the treatment of phosphates in all cases where the workmen would be inconvenienced by them.

#### *Disposal of Dust.*

The means noticed under this head are comprehended under two general methods, that of the well known "Cyclone" dust collector, and of chambers containing flannel or other kind of filtering cloth, from which the accumulated dust is periodically removed by shaking or beating.—*Oil, Paint, and Drug Reporter*.

#### JAPANESE SULPHUR MINES.

The export of sulphur from Hakodate shows a decrease from 7,096 tons, value 16,917*l.*, in 1887 to 3,609 tons, value 8,681*l.*, in 1888. This is attributable almost entirely to the fact that no vessels could be induced to call at the port to take the sulphur away, the price, delivered in Hakodate (2*l.* 3*s.* 6*d.* per ton), being sufficiently high to prevent its being shipped. The shipments last year went to San Francisco.

What prevents Japan from rivalling Sicily as a sulphur-producing country is the absence of facilities for increasing the output of sulphur and for shipping it. At present there is only one place where sulphur is worked on any scale, and that is Atosanobori, near Kushiro, on the south-east coast of the island on which Hakodate is situated.

The Atosanobori mine is part of an extinct volcano. The sulphur covers a considerable portion of the slopes of the hill and of the sides of the old crater. Supposing the ore to be only 4 or 5 feet thick on the surface, there must be at this place over 1,000,000 tons of high-class ore. Recent borings (by Japanese) gave the thickness of ore as 30 feet in some places, but it is probable that the richness of the ore decreases with the depth below the surface. It would be quite safe to count upon at least 5,000,000 tons of good ore. At present the ore yields over 50 per cent. of pure sulphur, a small portion of it being almost pure. The residue from the refining kettles would well repay a second treatment, as it appears to contain a considerable percentage of sulphur, as much as 15 per cent. probably, or about the average yield of the whole of the Sicilian sulphur ore.

The present output from Atosanobori does not exceed 10,000 tons of sulphur per annum (output about 9,000 tons in 1888). The cost of the sulphur, free on board at Kushiro, would be about 30*s.* 10*d.*—*Eng. and Min. Journal*.

#### THE METAL PRODUCTION OF RUSSIA.

A comparison has been made between the latest report of the Russian Mining Commission, edited by M. Konbeline,

and that published in 1878 by M. Skalkovsky. The report does not give any figures later than the end of 1887, but the comparison supplies important data for measuring the progress of the Russian metal industry. So far as the precious metals are concerned, the product of gold has fallen during these 10 years from 2,572 to 2,128 poods, while that of silver has increased from 699 to 939 poods, and that of platinum from 126 to 269 poods. The figures are different for the precious metals chemically refined, namely, 1,898 poods of gold and 1,043 poods of silver in 1887. Those for platinum are unknown, the melting of that metal being mainly carried on abroad. Notwithstanding the affinity that exists between silver and lead, and the increase in the produce of silver, less lead was extracted in 1887 than was the case 10 years before—60,428 poods instead of 85,281. The amount of gold extracted is less than it used to be. It appears that less and less auriferous soil is discovered in the region of Yakoutsk. On the other hand, the fact that more gold is found in the quartz mines than formerly (164 poods instead of 87) is of favourable augury for the future. It is not believed by Russian economists that there will be much progress in the gold industry until the great Siberian railway is finished, as this scheme takes away the labourers from all other work, and makes the price of machinery abnormally high. The only progress of the gold industry at the present moment is found in the province of the Amoor. Foreign competition has for a long time been injurious to the production of copper, but the raising of the Customs tariff has made an alteration by which the Caucasus has benefited. In 10 years the smelting of copper has risen from 214,865 to 304,607 poods. On the other hand, zinc has fallen from 283,398 to 221,250 poods, in consequence of the decline of the home demand. Very little tin is obtained in Russia (629 poods in 1887), and that only in Finland. Quicksilver, a rare metal, was not worked in Russia until 1886, but in 1887, 3,911 poods of it were obtained. During the 10 years the extraction of manganese rose from 11,790 in 1878 to 3,553,535 poods in 1887. In 1886, however, the figure was 1,000,000 poods higher. The sudden fall is due to the rivalry of Chili.—*Ibid.*

## IRON AND STEEL STATISTICS.

### STATISTICS OF CONVERTERS.

The numbers of converters operative and inoperative during 1889 were as under:—

District.	Number of Converters.					
	Operative.		Inoperative.		Total.	
	Acid.	Basic.	Acid.	Basic.	Acid.	Basic.
South Wales.....	20	..	6	..	26	..
Cleveland.....	6	10	2	..	8	10
Sheffield, &c. ....	14	..	10	..	24	..
Cumberland .....	10½	..	2½	..	13	..
Lancashire and Cheshire ...	10	..	10	..	20	..
Staffordshire, Scotland, &c. .	..	12½	..	3½	..	16
Totals .....	60½	22½	30½	3½	91	26

The average production per converter appears to have increased, as between 1888 and 1889, the average of the two years having been—

	Tons.
1888.....	23,003
1889.....	25156

### STATISTICS OF OPEN-HEARTH STEEL.

An attempt has been made to obtain for the present report, for the first time, the quantities of acid and basic open-hearth steel produced, with the following result:—

#### QUANTITIES OF ACID AND BASIC OPEN-HEARTH STEEL PRODUCED DURING THE YEAR 1889.

District.	Production of Open-Hearth Steel Ingots.		Total.
	Acid.	Basic.	
	Tons.	Tons.	Tons.
Scotland.....	437,605	2,460	440,065
North-East Coast .....	437,100	..	437,100
Wales (North and South)...	209,392	3,226	212,618
Sheffield, Leeds, &c.....	114,544	7,253	121,794
Lancashire and Cumberland	104,685	11,927	116,612
Staffordshire, Cheshire, &c...	54,138	16,842	70,980
Total .....	1,357,461	71,708	1,429,169

At the end of 1889 there were 274 acid and 17 basic open-hearth furnaces erected in Great Britain, making a total of 291, as compared with 288 furnaces at the end of the previous year. The number at the end of 1889 would have been larger but for the fact that in the interval one important works in South Wales has been reconstructed, and has now only 6 furnaces, as compared with 14 in 1888.—*Ironmonger.*

## BOARD OF TRADE RETURNS.

### SUMMARY OF IMPORTS.

	Month ended 30th April	
	1889.	1890.
	£	£
Metals.....	1,871,161	1,856,217

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

## I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

## APPLICATIONS.

5661. H. J. Rogers and J. Paramor. Improvements in revolving boilers used in paper making and other industries. April 15.

5847. C. Wood. See Class X.

5991. J. W. Claridge. Improvements in apparatus for feeding fuel to furnaces mechanically. April 21.

6032. M. W. Dewey. See Class XI.

6060. J. D. Churchill. Improvements in fluid-pressure reducing apparatus. April 22.

6088. E. Brook. Improvements in kilns. April 22.

6107. J. C. Mewburn.—From C. C. Peck, United States. Improvements in the evaporation of brine and other solutions or liquids, and in apparatus employed therein. Complete Specification. April 22.

6136. J. Klein. Apparatus for condensing or cooling gaseous or liquid substances. Complete Specification. April 22.

6221. J. W. Lovibond. Improvements in instruments for estimating, measuring, or comparing colour, texture, and appearance of transparent or opaque bodies, and for testing colour vision and light perceptive power. April 23.

6399. J. von Langer and L. Cooper.—From G. Pietzka, Austro-Hungary. Improvements in or connected with reverberatory furnaces. April 26.

6400. J. von Langer and L. Cooper.—From G. Pietzka, Austro-Hungary. Improvements in recuperators or apparatus for utilising the waste heat of furnaces. April 26.

6433. G. E. Davis and A. R. Davis. An improved furnace for conducting chemical operations. April 28.

6484. G. Fletcher. Improvements in evaporating pans. April 28.

6579. W. P. Thompson.—From I. D. Smead, United States. Improvements in and relating to heaters of desiccating apparatus. Complete Specification. April 29.

6864. J. J. Shedlock and J. J. Meldrum. See Class X.

6928. S. E. Martyn. Improvements in air compressors and the like. May 5.

6951. C. Kellner. Improvements in lining boilers or digesters used in the manufacture of paper pulp and for similar purposes. May 6.

7009. P. U. Askham and W. Wilson. Improvements in disintegrating apparatus, more especially intended for disintegrating phosphates and other similar substances. May 6.

7075. B. Hunt and W. M. Mackey. Improvements in filtering apparatus. May 7.

7296. C. D. Arhens. Improvements in apparatus for polarisation of light. May 10.

7696. F. N. Mackay. See Class XII.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1889.

6861. J. Price. Apparatus for expelling liquid from and compressing semi-fluid or plastic substances. April 23.

7343. J. Foster. Vacuum distilling and evaporating apparatus. April 30.

8169. Solvay and Co. See Class VII.

8872. W. L. Wise.—From Solvay and Co. Apparatus for the continuous treatment of pulverulent matters by fluids. May 21.

8928. F. N. Mackay.—From J. Baxter and J. Muter. Filter presses and filtering. April 23.

9041. D. B. Morison. Apparatus for evaporating liquids. April 23.

9850. J. Brown and G. Johnston. Vacuum drying apparatus. April 23.

10,907. W. P. Thompson.—From N. Notkin and P. Marix. Distilling products by means of steam, separating them according to their points of vaporisation, and apparatus therefor. May 14.

10,945. J. Vicars, T. Vicars, and J. Vicars, jun. Apparatus for feeding fuel to furnaces. May 14.

11,350. R. C. Garton, C. H. Garton, and W. Lawrence. Apparatus for evaporating, heating, or cooling liquids. May 21.

11,402. E. Bazin. Hydro-centrifugal apparatus for washing, amalgamating, and separating metallic ores, and for washing and separating other bodies of different densities. May 21.

1890.

2139. O. Bellot. Means for regulating the generation of heat in ovens, furnaces, &c. April 23.

2618. H. J. Haddan.—From S. T. Wellman. Method and mechanism for charging furnaces. April 30.

3261. H. H. Lake.—From O. H. Jewell. Apparatus for filtering water. April 30.

4354. A. Eickhorn and R. Jaspar. Hydrometers. April 30.

5267. A. Chapman. Construction and working of double, triple, and multiple-effect evaporating apparatus. May 14.

## II.—FUEL, GAS, AND LIGHT.

### APPLICATIONS.

5637. G. C. Fowler, M. B. Fowler, and G. A. Fowler. Improvements in or connected with night and other similar lights. April 14.

5788. S. Beson. An improved fire-lighter, and method of manufacture of the same. April 16.

5838. C. M. Pielsticker. Improvements in the distillation of mineral oils. April 17.

5971. J. Dewar and B. Redwood. Improvements in the distillation of oils and other viscous liquids. April 19.

6217. S. Griffin. Improvements in apparatus for producing combustible gas for gas-motor engines or other purposes. April 23.

6235. J. Hey and P. Hey. Improvements in fire-lighters. April 24.

6256. T. D. Rock. The application of anthracite gas for metallurgical and other purposes. April 24.

6282. R. de Soldenhoff. Improvements in means employed in charging coke ovens. April 24.

6323. T. T. Vernon. Improvements in or appertaining to apparatus for consuming smoke and economising fuel. April 25.

6463. E. Neave. Method of and apparatus for treating atmospheric air to obtain oxygen therefrom. Complete Specification. April 28.

6465. C. M. Pielsticker. Improvements in the distillation of hydrocarbon and other oils. April 28.

6466. C. M. Pielsticker. Improvements in the distillation of hydrocarbon and other oils. April 28.

6553. A. Longsdon.—From F. Salomon, Germany. Improvements in obtaining oxygen gas from atmospheric air. Complete Specification. April 29.

6575. J. H. W. Stringfellow. Improvements in the manufacture of gas and apparatus therefor. April 29.

6584. J. J. Shedlock and T. Denny. Improvements in gas producers. Complete Specification. April 29.

6800. W. C. Andrews. Improvements in the purification of illuminating or heating gases. Complete Specification. May 2.

6804. W. C. Andrews. Improvements in apparatus for the purification of illuminating gas. Complete Specification. May 2.

6877. J. J. Hiertz and A. S. Garnett. Combustible coal brick. Complete Specification. May 3.

6900. W. Gordon and G. A. Newton. Improvements in fire-lighting and fuel. May 5.

6966. J. Horne. See Class XVIII.—B.

7040. J. J. Cooper. Improvements in "carburettors." Complete Specification. May 6.

7063. H. Fourness. Improvements in the method of and in apparatus for the manufacture of carburetted water-gas. May 7.

7144. T. Williams. The manufacture of smokeless fire-lighters. May 7.

7252. R. C. Lindsay. An improved process for the manufacture of illuminating gas, and apparatus therefor. May 9.

7277. G. M. Cruikshank.—From J. C. Reissig, Argentine Republic; J. Landin, Sweden; and P. F. Macallum, Scotland. Improvements in the manufacture of gas for illuminating and heating purposes, and application thereof. May 10.

7335. G. M. Cruikshank.—From J. C. Reissig, P. F. Macallum, and J. Landin. Improvements in incandescent lighting, by means of calcareous gases, and in apparatus therefor. May 12.

7569. T. Le Poidevin. Apparatus for producing air gas. May 15.

7705. H. Rudge. Improvements in or relating to candles. May 17.

7714. C. B. Newton. Apparatus for automatically delivering any proportionate quantity of oxygen, air, or other gaseous body or bodies into gas purifiers or other vessels, pipes, or conduits, irrespective of any pressure there may be in such gas purifiers or other vessels. May 17.

7739. J. von Langer and L. Cooper. Improvements in or connected with the manufacture of water-gas. May 17.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

8040. A. Myall.—From J. H. Lancaster. Artificial fuel. May 21.

8993. S. W. Wilkinson. Producing clean gaseous fuel for the evaporation of brine, and recovering the ammonia formed during production of said gaseous fuel. May 21.

9783. A. Nielson and W. Black. Distilling shale, coal, and other oil and tar-yielding minerals, and retorts therefor. April 23.

10,164. W. Crookes and F. I. Ricarde-Seaver. Treatment of water-gas. April 23.

10,277. J. Dewar and B. Redwood. Distillation of mineral oils and like products, and apparatus therefor. April 30.

10,340. S. Clarke. Night-lights. May 7.

10,392. H. J. Haddan.—From F. F. Amoroso. Burning liquid fuel in boiler furnaces, &c. April 30.

10,488. J. H. R. Dinsmore. Apparatus used in the manufacture of gas from coal, &c. May 14.

10,581. J. C. Johnson. Producer for making producer-gas, water-gas, and coke. May 7.

11,104. J. Carr. Manufacture of illuminating gas from coal. May 21.

11,125. F. Sanders. Retorts for producing gas. May 14.

11,164. F. T. Schmidt. Method and apparatus for consuming smoke. May 21.

11,654. J. Drabble. Apparatus for the prevention and consumption of smoke, and more perfect combustion of fuel. May 21.

17,817. E. de Pass.—From E. Demoguin and L. Bourdier. Improved fire-lighter and fuel. April 23.

1890.

2611. W. W. Popplewell.—From H. Couried. Artificial fuel. March 26.

3306. H. Ekeland. Furnace for continuous carbonising or coking. April 23.

3363. C. Heucken. Coke ovens. May 14.

5464. J. G. Hawkins and J. Barton. Vertical gas retorts and attachments. May 14.

#### IV.—COLOURING MATTERS AND DYES.

##### APPLICATIONS.

5721. J. Hall. Improvements in the manufacture or production of colouring matters. April 15.

5722. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture of diquinolyline derivatives. April 15.

5723. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture of phenacetine derivatives. April 15.

5736. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, A. F. Poirrier, and D. A. Rosenstiehl, France. Manufacture of azo colouring matters derived from azoxyamines. April 15.

5737. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, France. Manufacture of colouring matters derived from fluoresceine. April 15.

5777. O. Imray.—From The Farbwerke vormals Meister, Lucius and Brüning, Germany. Production of grey basic colouring matters by the action of hydrochlorate of nitrosodimethylaniline, or hydrochlorate of nitrosodiethylaniline upon 1·5 dioxynaphthalin, and upon 1·2 tetroxydinaphthyl. April 16.

5780. O. Imray.—From The Farbwerke vormals Meister, Lucius and Brüning, Germany. Production of black colouring matters from amidoflavopurpurin and amidanthrapurpurin. April 16.

6195. S. S. Bromhead.—From Die Chemische Fabrik Grunau, Laudshoff and Meyer, Germany. A process for the preparation of a blue colouring matter for cotton. April 23.

6274. O. Imray.—From The Farbwerke vormals Meister, Lucius and Brüning, Germany. Production of blue-grey colouring matters from indulines soluble in alcohol, resulting from the action of hydrochlorate of amido-azobenzol upon an aqueous solution of hydrochlorate of aniline or orthotoluidine. April 24.

6346. The British Alizarine Co., Limited, and D. C. Bendix. Manufacture of soluble alizarine compound for dyeing and printing. April 25.

6486. J. Imray.—From La Société Anonyme des Matières Colorantes et produits Chimiques de St. Denis, France. Manufacture of nitrated colouring matters. April 28.

6729. C. Dreyfus. Improvements in the manufacture and production of colouring matters. May 1.

6874. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in the manufacture and production of substantive colouring matters. May 3.

6875. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in the manufacture and production of sulpho-acids of a red basic naphthalene colouring matter. May 3.

6879. H. H. Lake.—From A. Leonhardt and Co., through Messrs. Wirth and Co., Germany. Improvements in the manufacture of colouring matters. May 3.

6931. C. D. Abel. Improvements in the manufacture of colouring matters. May 7.

6932. C. D. Abel. Improvements in the manufacture of colouring matters. May 7.

6946. S. Pitt.—From L. Cassella and Co., Germany. Production of new basic blue colouring matters. May 5.

7018. W. Cole. Improvements in the manufacture of indigo. May 6.

7421. R. Holliday. Improvements in the production and utilisation of a new hydroxy-quinone. May 13.

7515. W. Akam. A new or improved copying ink. May 14.

7575. A. G. Green and T. A. Lawson. A process for the production of new amido bases. May 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

8156. H. H. Lake.—From Leonardt and Co. Manufacture of amido-phenols. April 30.

8299. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co. Azo colouring matters for dyeing and printing. April 30.

8673. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of colouring matter and of leuco-bases employed therein. May 7.

8750. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co. Basic colouring matter. May 7.

9427. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Colouring matter of the oxyketone group, for dyeing and printing with the aid of mordants. April 23.

10,934. The Clayton Aniline Company, Limited, and C. Dreyfus. Preparation of new sulphonic acids for manufacture of colouring matters. May 14.

11,613. O. Imray.—From The Society of Chemical Industry, Basle. New red and blue colouring matters. April 30.

11,848. O. Imray.—From The Society of Chemical Industry, Basle. Blue colouring matter. April 30.

15,175. O. Imray.—From The Farbwerke vormals Meister, Lucius and Brüning. Production of amido-oxy-naphthalin-disulphonic acid, and amido-dioxy-naphthalin-monosulphonic acid, and the manufacture of their diazo compounds and of azo colouring matters therefrom. May 14.

15,176. O. Imray.—From The Farbwerke vormals Meister, Lucius and Brüning. Production of amido-naphthol-monosulphonic acids, and manufacture of their diazo compounds and azo colouring matters therefrom. May 14.

1890.

3095. H. H. Leigh.—From R. G. Williams. Manufacturing of colouring matters. April 23.

#### V.—TEXTILES, COTTON, WOOL, SILK, Etc.

##### APPLICATIONS.

6127. A. H. Norman. Improvements in the treatment of ramie. April 22.

6155. G. H. Croker. An improved process for the removal of fibre or lint from and cleaning cotton seed, and means or apparatus employed therein. April 23.

7389. J. Longmore and W. L. Watson. Improvements in or relating to the decortication of rhea, jute and other fibrous vegetable stems. Complete Specification. May 12.

7390. J. Longmore and W. L. Watson. Improvements in or relating to the decortication of rhea, jute, and other fibrous vegetable stems. Complete Specification. May 12.

7423. W. Peters. Improvements in the method of, and in means and appliances for, tarring, colouring, and otherwise preparing thread, hemp, jute, or other twine for sewing, and in feeding or supplying the same. May 13.

7568. K. T. Sutherland and G. Esdaile. An improved method of treating animal fibres so that they will flock and spin more easily. May 15.

#### COMPLETE SPECIFICATION ACCEPTED.

1889.

14,751. I. Smith. Treatment of woollen, worsted, back-worsted, unions, and other woven fabrics. May 14.

#### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

##### APPLICATIONS.

6202. S. Stepanow. See Class XI.

6213. H. J. Haddan.—From L. Appelmans and L. Tibbaut, Belgium. Method for colouring and marbling paper on the paper machine. April 23.

6315. R. Harrison. Washing, scouring, and bleaching cotton, linen, wool, or other fibrous materials. April 25.

6506. W. H. Booth. Improved process and means to be employed in connexion with and relating to the operation of dyeing velvets, plushes, and like materials; applicable also in the carrying out of proximate processes relating to the treatment of fibrous substances or materials, either in a manufactured, partly manufactured, or pulpy state. April 28.

6612. R. T. Webb. Expediting and improving the process of bleaching linen, cotton and other yarns in the hank. April 30.

7198. W. H. Spencer. An improved process of bleaching textile fibres. May 8.

7202. P. Cavaillès. An improved process for dyeing wool, and apparatus for use in the same. May 8.

7522. W. Elbers. Process for obtaining designs or patterns in red colour on textile fabrics dyed with indigo. May 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

8107. V. Schevelin and P. Mindovsky. Cleansing and bleaching fibrous substances, and fixing colouring matters thereon by means of acid and alkaline residues of naphtha manufacture, or analogous bodies. April 23.

9836. W. E. Heys.—From C. Vandermeirssche. Method and apparatus for dyeing, &c. yarns and textiles. April 23.

10,993. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of tannin compounds, especially for printing purposes. May 14.

1890.

1702. G. H. Craven. Dyeing machines. May 14.

4683. A. J. Boulton.—From A. and M. Koblenzer. Dyeing yarns. April 30

## VII.—ACIDS, ALKALIS, AND SALTS.

## APPLICATIONS.

6046. J. Pointon. Improvements in apparatus for the manufacture of alkaline silicates and aluminates, applicable also in part as a gas-producer for use with pig-iron or other blast furnaces. April 22.

6047. J. Pointon. An improved method of manufacturing alkaline aluminates. April 22.

6048. J. Pointon. An improved method of manufacturing alkaline silicates. April 22.

6333. F. M. Lyte. Improvements in the production of magnesic oxychloride. April 25.

6416. G. E. Davis and A. R. Davis. Improvements in the preparation of chlorine. April 28.

6549. J. Plummer, jun. Process to obtain hydrochloric acid and ammonia. April 29.

6698. G. E. Davis and A. R. Davis. Improvements in the manufacture of chlorine. May 1.

6758. J. McEwen. A new or improved continuous method of generating carbonic acid gas from a soluble carbonate in solution and an acid in solution, and in apparatus connected therewith. May 2.

6831. G. E. Davis and A. R. Davis. Improvements relating to the preparation of chlorine. May 3.

7058. J. Y. Johnson.—From J. Marx and Dr. Weller, Germany. Improvements in and apparatus for or connected with the obtaining, liquefying, and storage of chlorine. May 6.

7247. H. Baudouin and P. F. Escarpié. A process and apparatus for the manufacture of ammonia. May 9.

7527. J. Vivian and G. Bell. Improvements in apparatus for use in the manufacture of bicarbonate of soda by the ammonia-soda process. May 14.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

8169. Solvay and Co. Distillation and condensation of ammoniacal and other liquids, and apparatus therefor. April 30.

8177. E. Hermite, E. J. Paterson, and C. F. Cooper. Bleaching and disinfecting liquor. May 21.

8779. J. J. Alsberge. Manufacture of chlorine in combination with the ammonia or the Leblanc process. April 23.

8862. W. Thorp. Method and apparatus for condensing and utilising sulphuric and sulphurous acid fumes. April 30.

8993. S. W. Wilkinson. See Class II.

9225. T. Turner. Treatment of waste pickle from galvanising works. April 23.

9680. A. G. Greenway. Galvanising iron, and utilising the waste acids therefrom. April 23.

10,142. A. S. Ramage. Preparing iron oxides from ferrous solutions. April 30.

10,554. T. Parker and A. E. Robinson. Utilisation of sulphate of iron galvanising pickle. May 7.

11,351. R. C. Garton, C. H. Garton, and W. Lawrence. Crystallisation of salts or crystallisable acids. May 21.

13,003. A. W. Ellis. Treatment and distillation of ammoniacal liquor of gas and other works, manufacture of sulphate of ammonia therefrom, apparatus therefor, and prevention of nuisance therefrom. May 14.

1890.

4652. J. C. Mewburn.—From C. C. Peck. Purifying brine. May 7.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

## APPLICATIONS.

5815. S. R. Audnitz. Substitute for glass. April 17.

5830. W. H. Sharman and R. E. Oldham. The making of earthenware, granite, or china by a new machine press, such as oval, square, octagon, round dishes, bakers, plates, hand basins, &c. April 17.

5970. H. M. Ashley. Improvements in the manufacture of ceramic ware and apparatus for that purpose. April 19.

6058. G. Scott. A new or improved method or manufacturing slates from glass and other materials, and in the apparatus therefor. Complete Specification. April 22.

6196. W. R. May. Improvements in the manufacture of glazed bricks and tiles. April 23.

6231. A. Fielding. Improvements in ovens or kilns used for firing or hardening articles of pottery. Complete Specification. April 24.

6722. J. Kirkby. Drying kiln (for burning bricks or earthenware of like nature). May 1.

6979. J. H. Lewis. An improved asbestos composition shadow for glass and other furnaces. May 6.

7099. B. F. McTear. Improvements in or appertaining to kilns for burning bricks, terra-cotta, or the like. May 7.

7145. D. Rylands. Improvements in machinery for the manufacture of bottles and other glass ware, and in the processes of working the same. May 8.

7184. C. H. Edwards. Improvements in the manufacture of gas retorts, drain pipes, and other earthenware or clay ware. May 8.

7327. F. O. Thompson. Improvements in pots for melting glass. May 10.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

7245. W. H. Hollingshead and H. Griffiths. Decorative pottery ware. May 7.

7761. O. P. Erard and B. J. Round. Depositing metal on glass, porcelain, &c. April 23.

8760. A. Drummond. Apparatus for manufacture of corrugated, ribbed, or other glass having patterns on surface. April 23.

10,088. The Brosely Tileries Company, Limited, and J. Crump. Earthenware quarries or tiles. April 23.

10,887. D. Chapman. Casting or forming articles of pottery, china, and earthenware. May 14.

11,064. E. E. Cousins.—From B. E. Olsen. Fusible compounds suitable for drain pipes, flushing chambers, and the lining of conduits. May 14.

11,690. M. Poumarède. Manufacture of flower vases, pots, &c. May 14.

1890.

2583. J. H. Bailey. Glazed or enamelled railway signal arms. March 26.

3229. E. Leuk and H. Aynsley. Means for supporting biscuit or glost ware in kilns. April 23.

4021. A. J. Boulton.—From P. Sievert. Production of solution of alkaline silicate or water-glass, and apparatus therefor. April 23.

# IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

## APPLICATIONS.

5719. W. R. Taylor. Improvements in and means for the manufacture of cement. April 15.

5827. A. B. Rigby. An improved form and combination of concrete blocks. April 17.

6555. G. Brewer.—From J. C. Firth, New Zealand. A new or improved insulating and fire-proofing material or composition. April 29.

6711. F. C. Goodall. An improved marine cement. May 1.

6855. G. Higham. An improved composition for use in and in connexion with the manufacture of Portland cement. Complete Specification. May 3.

6952. C. Kellner. Improvements in coating iron, steel, or other metals or materials with Portland or other cement. May 6.

7107. J. P. Bayly.—From P. Arnold, United States. Improvements in paving blocks. May 7.

7641. A. M. Thomson. Improvements in paving, said improvements being also applicable to tiles and slabs. May 16.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

8428. M. May. Artificial polished or ground stone. May 21.

8795. A. N. Ford. Materials for roofing and other purposes. March 26.

9666. E. Numan. Base or foundation for the reception of plaster, &c. April 23.

11,128. G. Batchelor. Arrangements for drying slurry by the waste heat from cement kilns. April 23.

1890.

1097. H. H. Lake.—From J. F. Gesner. Manufacture of an artificial solid material, and apparatus therefor. May 21.

3025. G. West. Plastering material. May 21.

# X.—METALLURGY, MINING, Etc.

## APPLICATIONS.

5608. J. Letcher. Improvements in and connected with furnaces for recovering tin from tin-slag. Complete Specification. April 14.

5638. T. Teague. A process for extraction of tin from the slag or debris of tin smelting. April 14.

5641. H. Howard, of the Firm of Lloyd and Lloyd. Improvements in the manufacture of iron and steel tubes. April 14.

5659. G. W. Marble and M. W. Simons. Improvements in forging metals and in machinery therefor. Complete Specification. April 15.

5847. C. Wood. Improvements in the manufacture of fibrous material from slag or other vitreous substance, and in the apparatus used in such manufacture. April 17.

5894. A. J. Boulton.—From J. W. Bookwalter, Germany. Improvements in converters. Complete Specification. April 18.

5937. W. C. Loe. Improved method or process for treating metal-bearing bodies, and the recovery of metals therefrom. April 18.

6046. J. Pointon. See Class VII.

6216. C. T. J. Vautin. An improved hydrometallurgical method of and means for the extraction of gold or platinum from their ores. April 23.

6256. T. D. Rock. See Class II.

6316. S. Fox. Improvements in the method or process of manufacturing steel in connexion with the open-hearth system. April 25.

6462. H. Napier and T. Carr. Improvements in the production of metals and metallic alloys from their ores and oxides. April 28.

6524. W. Ryland. An improved process for securing the better adhesion of metals when electrically deposited or coated. April 29.

6529. J. H. Bramwell. An improved process to be employed for hardening steel. Complete Specification. April 29.

6572. A. McLean. Improvements in the preparation of metal for various purposes. April 29.

6645. J. H. Lancaster and M. R. Conley. Improvements in the manufacture of iron or steel. April 30.

6670. S. O. Cowper-Coles. Improvements in the deposition of alloys. April 30.

6694. B. Edwards, L. Davies, and W. R. Williams. An air receiver applied especially to the casting of ingots, shafts, cannons, and all manner of castings cast perpendicularly. May 1.

6821. Sir H. H. Vivian, Bart. Improvements in the manufacture of copper. May 2.

6864. J. J. Shadlock and J. J. Meldrum. Improvements in apparatus for the production of gases for metallurgical and other purposes. Complete Specification. May 3.

6936. G. Bamberg. Extraction of gold from ore. May 5.

6960. J. Neill. Improvements in the manufacture of steel plated and gated ingots, and in the moulds for same. May 6.

6980. A. C. Chance. Making sleeves, nozzles, and stoppers used in the manufacture of steel. May 6.

7055. A. Sinclair. Improvements in the treatment of ores, matte, spieess, and other products containing copper, together with nickel or cobalt. May 6.

7070. J. Heaton and G. H. Holden. Improvements in the manufacture of steel and iron, and in apparatus to be employed in such manufacture. May 7.

7129. J. D. Danton. A process and apparatus for reduction of iron and other oxide ores, and for fusion and purification of the produced metals. May 7.

7253. W. Hodge. Improvements in converting iron into steel, or the steelifying of wrought iron objects in a manufactured or partly manufactured state. May 9.

7305. J. Allan. A new or improved composition of metals. May 10.

7461. H. H. Lake.—From The Russel and Erwin Manufacturing Company, United States. Improvements relating to the annealing of metals. Complete Specification. May 13.

7464. W. J. Smuts.—From J. Cronoun, W. Hicks, and J. Laitz, Transvaal. An improved amalgamator, suitable for use in the separation of gold from quartz. May 13.

7647. C. Knight and W. F. Sharp. A new or improved solution for use in the preparation of copper utensils for re-tinning. May 16.

7733. H. H. Lake.—From G. W. Cummins, United States. An improved process and apparatus for preventing the access of air to iron and steel during annealing. Complete Specification. May 17.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

843. J. H. Selwyn. Hydrometallurgical processes. April 23.

9987. The Alkaline Reduction Syndicate, Ltd. Treatment of zinc ores. May 21.

10,154. J. C. Bull. Manufacture of copper alloys. May 21.

10,274. H. Cave. Process and apparatus for amalgamation of gold and silver contained in their ores. May 21.

10,298. J. H. Pollok. Wet method of extracting gold, and apparatus therefor. April 30.

10,394. J. Harper. Treating gold and silver ores by wet method. April 30.

10,835. T. Hydes. Treating blast-furnace and other slags, and apparatus therefor. May 14.

10,836. T. Hydes. Treating blast-furnace and other slags, and apparatus used therein. May 14.

11,344. C. F. Jozs. Manufacture of ornamental plates of metal. May 21.

11,402. E. Bazin. See Class I.

20,223. E. Taussig. Improvements in casting. April 23.

1890.

70. I. Bang and A. Rudin. Separating tin from other metals and recovering tin from tin-plate scrap, &c. April 30.

128. I. Bang and A. Rudin. Production of tin plates, and apparatus therefor. April 23.

1754. G. Höper. Method and apparatus for manufacturing dense-metal castings, and sheet metal and wire therefrom. April 23.

2981. M. F. Coomes and A. W. Hyde. Manufacture of steel. April 2.

3440. J. L. Sebenius. Removing gases and impurities from metals or alloys. May 14.

3483. L. L. Burdon. Seamless compound ingots or bars and wire. April 23.

4386. J. von Ehrenwerth. Producing iron and steel from ores and other materials. May 14.

4690. H. J. Haddan.—From G. Conkling. Concentrating magnetic iron ore. April 30.

5608. J. Letcher. Improvements in and connected with furnaces for recovering tin from tin-slag. May 21.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

## APPLICATIONS.

5810. F. L. Rawson.—From Messrs. Hartmann and Braun, Germany. An improved galvanic battery. April 17.

5920. P. Schoop. Improvements in accumulators or secondary batteries. April 18.

5938. K. E. Boettcher. A new or improved secondary element. April 18.

6032. M. W. Dewey. Improvements in electric heating apparatus. Complete Specification. April 21.

6177. G. Barker.—From H. Woodward, Canada. Improvements in secondary batteries. April 23.

6202. S. Stepanow. An electrolytic process for the preparation of a liquid for bleaching fabrics, paper pulp, and other matters. April 23.

6223. M. Ancizar.—From R. Z. Bayon, South America. Improvements in galvanic batteries. April 23.

6236. A. J. Jarman. An improved storage or tertiary electric battery. Complete Specification. April 24.

6266. J. Marx. Improvements in means for use in electrolysis. April 24.

6476. H. T. Eagar and R. P. Milburn. Improvements in electrical batteries. April 28.

6795. H. Edmunds. Improvements in secondary or storage batteries. May 2.

6924. H. T. Eagar and R. P. Milburn. Improvements in electrical batteries. May 5.

7132. H. H. Lake.—From Lacombe et Cie., France. Improvements in the manufacture of carbon electrodes. May 7.

7185. W. P. Thompson.—From C. L. Coffin, United States. Improvements in welding metals electrically and apparatus therefor. Complete Specification. May 8.

7186. W. P. Thompson.—From C. L. Coffin, United States. Improvements in welding metals electrically, and apparatus therefor. Complete Specification. May 8.

7383. J. N. Levens. An improved battery element. Complete Specification. May 12.

7399. R. Kennedy. Improvements in heating by magnetism and electricity. May 13.

7444. A. Million and P. Bony. Improvements in and relating to galvanic batteries. Complete Specification. May 13.

7513. W. L. Wise.—From P. Schoon, Switzerland. Improvements in the manufacture of electrodes for secondary batteries. May 14.

7518. A. Walker and T. J. D. Rawlins. Improvement in means for preventing polarisation in primary batteries. May 14.

7581. W. A. Thoms. Improvements in the electro deposition of heavy metals and their alloys. May 15.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

9183. M. Sussmann. Exciting liquid for electric batteries. May 7.

10,061. G. J. Atkins. Apparatus for separating gold and other metals from their ores by the aid of electricity. April 30.

10,695. H. H. Lake.—From C. A. Hussey and E. H. Brown. Electric batteries. May 14.

10,696. H. H. Lake.—From C. A. Hussey and E. H. Brown. Electric batteries. May 14.

11,049. J. J. Wood. Dynamo-electric machines. May 7.

11,070. J. Y. Johnson.—From A. L. Riker. Elements or plates for secondary batteries. May 14.

13,795. P. von Knobloch. Turning artificial and natural light into electrical current. April 23.

18,481. C. Payen. Electric batteries. April 30.

19,129. C. R. Bonne.—From H. Meinecke, jun. Electric dry batteries. May 7.

1890.

350. L. Epstein. Electrodes for primary and secondary batteries. May 14.

2819. C. Lütke. Electrolytic solution for galvanic batteries. March 26.

3008. W. B. Hollingshead. Secondary or storage batteries. April 9.

3013. C. J. Hartmann. Storage batteries. April 9.

3439. S. C. C. Currie. Storage batteries. April 30.  
 3455. H. H. Lake.—From T. Ewing. Secondary batteries. April 23.  
 3717. L. Weigert. Electrolytic solution for galvanic batteries. April 30.  
 4657. H. H. Lake.—From E. Thomson. Soldering or uniting metals by electricity, and apparatus therefor. April 30.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

### APPLICATIONS.

5620. J. Bowden and S. Hern. Improvements in the manufacture of soap for washing purposes. April 14.  
 5833. G. Tall. Refining cotton and other oils. April 17.  
 6268. A. W. Mellwaine. Improvements in the treatment of rape and other seed preparatively to the extraction of oil therefrom, and in apparatus applicable therefor. April 24.  
 6706. C. W. Kimmins and T. Craig. Improvements in the separation of fatty or greasy matters from the wash waters of wool-washing or scouring establishments. May 1.  
 6834. J. Taylor. A new or improved process and apparatus for the recovery of glycerin and salt from soap-makers' lyes. May 3.  
 7019. C. A. Serre. An improved manufacture of soap. May 6.  
 7117. H. Scott. Improvements in the manufacture of soap. May 7.  
 7142. H. Stern. Improved method of decolorising mineral, animal, and vegetable oils, fats, and the like, and the employment of silicic acid for the purpose. May 7.  
 7696. F. N. Mackay. Improvements in appliances for cooling oil and like liquids. May 17.  
 7706. J. A. Clough. Improvements in or appertaining to the manufacture of soap. May 17.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

8567. J. Taylor. Soap powder. April 30.  
 8740. W. P. Thompson.—From A. Schumacker and C. Tschiffeli. Extracting oil, &c. from seeds or the like. April 23.  
 9201. J. Snowdon. Toilet and cleansing soaps. May 21.  
 18,345. H. A. A. Dombrain and O. Trumper. Apparatus for extracting fatty and other matter by means of volatile solvents. April 30.

## XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

### APPLICATIONS.

6805. W. P. Thompson.—From A. F. von Pereira, Germany. Improvements in or appertaining to paints, colours, varnishes, and distempers, and in the method of applying them to canvas or other like surfaces. May 2.  
 6850. E. Parry and H. Foskett. A white pigment to be used in the manufacture of paints and colours. May 3.  
 7260. M. N. D'Andria. Improvements in the treatment of salts of iron and oxide of iron to obtain pigments, and in the utilisation of products therefrom. May 10.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

- 10,428. I. M. Lamb and D. Boyd. Lacquers and varnishes. April 30.  
 18,286. T. Pridham. Preservative and waterproof coating for metals, timber, masonry, &c. April 23.  
 20,289. J. Y. Johnson.—From N. C. Mitchell. Treating waste rubber goods to recover rubber therefrom, production of new product thereby, and apparatus therefor. May 14.

1890.

1684. A. J. Boulton.—From N. A. Bibikof. Improvements in paints. May 7.  
 2308. H. Beck.—From E. Schaal. Production of resin acid esters, and manufacture of lacquers and varnishes therefrom. April 23.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

### APPLICATIONS.

5966. W. R. Pullman and H. Smith. Improvements in machinery or apparatus for finishing green, or manufactured, or partly manufactured hides or skins. April 19.  
 7509. F. R. Maggs. The preparation of skins, kips, and hides by an improvement in the process known as "un-hairing" or pulling. May 14.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

9776. B. Nicholson and T. Pulmer. Means for tanning hides, skins, &c. May 21.  
 10,900. W. G. Richardson. Liquid waterproof glue. May 14.

## XV.—AGRICULTURE AND MANURES.

### APPLICATION.

5614. J. M. Fletcher. See Class XVIII.—A.

### COMPLETE SPECIFICATION ACCEPTED.

1889.

9087. J. W. Lodge. Partially destroying and mixing night soil and other refuse, and converting same into manure. May 7.

## XVI.—SUGARS, STARCHES, GUMS, ETC.

## APPLICATIONS.

7737. A. Niemöller. The production of a new glutinous material similar to gum arabic and other by-products from the seed kernels of the fruit of the carob tree (*Ceratonia*). May 17.

## COMPLETE SPECIFICATIONS ACCEPTED.

1890.

1247. A. Fairgrieve. Manufacture of raw or refined sugar, and apparatus therefor. April 23.

3589. C. Steffen. Process for manufacture of sugar. May 14.

4181. S. Spitzer. Method and apparatus for manufacture of starch, and treatment of the residues obtained therein. May 21.

## XVII.—BREWING, WINES, SPIRITS, ETC.

## APPLICATIONS.

5629. R. Haddan.—From J. B. Cabean, Belgium. Improved apparatus for brewing and storing beer in casks. April 14.

5673. J. Salamon. An improved fermenting process for beer, wine, and other fermentable liquids. April 15.

6075. F. M. Maynard. The aëration of yeast for exciting alcoholic fermentations or "yeast aëerator." April 22.

6220. H. H. Lake.—From A. Joergensen and A. Bergh, Sweden. Improvements in apparatus for the production of yeast and similar substances. April 23.

6337. W. Paterson. A new or improved process for preventing and arresting the development of acids during the process of malting barley and the storage of the same or other cereals such as rye, oats, or wheat, and in the infusion whilst macerating or infusing malted barley for the manufacture of concentrated extract of malt, or for all brewing purposes, or for the manufacture of malt vinegar. Complete Specification. April 25.

6480. G. Schneider. Method for the production and storing of beer without contact with the atmosphere. Complete Specification. April 28.

6587. W. T. Whiteman.—From F. Haecck, Belgium. A new or improved process and apparatus for the distillation and rectification of alcohols. Complete Specification. April 29.

7017. W. Cole. Improvements in the manufacture of beer and like fermented liquors. May 6.

7098. A. J. Bonlt.—From La Société Generale de Maltose, Belgium. Improvements in or relating to the manufacture of maltose, or to the fermentation of amylaceous matter. May 7.

7195. J. Campbell. A new or improved process for the recovery and utilisation of yeast. May 8.

7268. W. Dawson. Improvements relating to distillers' safes, said improvements being also applicable for check sampling the spent wash at outlets of "patent stills." Complete Specification. May 10.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

7909. A. Perry. Preparation of rice and other grain or cereals for brewing, &c., and apparatus therefor. May 21.

9276. A. Gough, sen. Apparatus for making and drying malt. May 7.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

## APPLICATIONS.

*A.—Chemistry of Foods.*

5614. J. M. Fletcher. Improvements in apparatus for the compression and preservation of vegetable products. April 14.

6102. W. S. Simpson. Improved means and appliances for preserving flesh food. April 22.

6421. A. G. Cunningham. An improved bread for dyspeptics. Complete Specification. April 28.

6883. W. J. Clarke. An improved process for preserving milk and cream. May 3.

6901. C. R. C. Tichborne and W. McDonnell. Aërated milk. May 5.

7193. A. S. Krueger and J. B. Black. Improvements in and relating to alimentary substances. May 8.

*B.—Sanitary Chemistry.*

6245. C. G. Moor. Improvements in the treatment of sewage. April 24.

6252. J. Longshaw. Improvements in apparatus for filtering or purifying water, sewage, or other liquids. April 24.

6397. F. B. Hill. Improvements relating to the treatment of sewage and the ventilation of drains and sewers, and to apparatus therefor. April 26.

6660. M. M. Brophy. Improvements in furnaces chiefly designed for destroying organic substances. April 30.

6966. J. Horne. Improved method and apparatus for hermetically carbonising vegetable and other products, and also for drying waste vegetable and other products for fuel and other purposes. May 6.

7165. F. N. Mackay. Improvements in apparatus for drying sludge or like matter. May 8.

7419. W. Walkington. An improved city and town refuse destructor. May 13.

7500. L. Hesse. Improvements in destructors for town and other refuse. Complete Specification. May 14.

7673. E. L. Mayer. Improvements in or connected with the treatment of sewage. May 16.

*C.—Disinfectants.*

5677. W. Radam. A fumigating composition for preserving and purifying purposes. April 15.

## COMPLETE SPECIFICATIONS ACCEPTED.

*A.—Chemistry of Foods.*

1889.

8945. J. L. Johnston. Preparation and combination of animal substances with vegetable substances for use in food. May 7.

10,352. G. A. Brinck and A. W. Rhenström. Food preparations. May 7.

*B.—Sanitary Chemistry.*

1889.

9763. G. Brownen and J. Gamgee. Bleaching, purifying, disinfecting, and preserving substances, and apparatus therefor. May 21.

9777. B. Nicholson and T. Palmer. Treatment of sewage, &c., for purification thereof, and obtainment of products therefrom. 21 May.

*C.—Disinfectants.*

1889.

8177. E. Hermite, E. J. Paterson, and C. F. Cooper. See Class VII.

16,369. J. Orchardson. Means and apparatus for disinfecting, destroying vermin, &c. May 7.

1890.

5677. W. Radam. A fumigating composition for preserving and purifying purposes. May 21.

## XIX.—PAPER, PASTEBOARD, Etc.

## APPLICATIONS.

6348. H. H. Lake.—From J. H. Carpenter and C. E. O'Hara, United States. Improvements in the manufacture of coloured paper. Complete Specification. April 25.

6458. P. Whiteside. A new or improved absorbent writing paper. April 28.

6644. J. Johnston and G. Johnston. Improvements in and relating to the treatment of paper-making fibre materials. April 30.

6993. C. Kellner. Improved apparatus for separating or disintegrating fibres in the manufacture of paper pulp. Complete Specification. May 6.

## COMPLETE SPECIFICATION ACCEPTED.

1889.

10,911. J. R. Thame and H. Sanguinetti. Manufacture of hollow ware from paper or like pulp, and apparatus therefor. May 14.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

## APPLICATIONS.

5940. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes, France. An improved method of and apparatus for extracting and purifying perfumes, oils, and other like substances. Complete Specification. April 18.

6620. F. Valentiner. A new manufacture of hydrocarbons and of derivatives which are applicable as perfumes or odoriferous bodies. April 20.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

11,099. T. Parker and A. E. Robinson. Manufacture of carbon bisulphide. May 14.

1890.

1988. F. L. Johnstone. Apparatus for filtering and derisining perfumes, tinctures, essences, &c. April 23.

5367. H. H. Lake.—From W. V. McKenzie and H. J. Braker. Refining apparatus for camphor, &c. May 21.

## XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

## APPLICATIONS.

5742. E. Fairweather. Developing photographic plates or other substances carrying a sensitive film. April 16.

6028. P. Rudolph. An improvement in photographic objectives. Complete Specification. April 21.

6029. E. Abbe and P. Rudolph. Improvements in photographic objectives. Complete Specification. April 21.

6066. B. Jumeaux. Improvements in or relating to developers for use in photography. April 22.

7453. A. G. Green, C. F. Cross, and E. J. Bevan. A process for photographing by means of organic compounds. May 13.

## COMPLETE SPECIFICATION ACCEPTED.

1889.

7747. W. F. Green. Rendering cardboard, paper, &c., impervious to the action of photographic chemicals, and suitable for photographic purposes. May 7.

## XXII.—EXPLOSIVES, MATCHES, Etc.

## APPLICATIONS.

5640. C. Watson. Improvements in electric safety fuses. April 14.

5948. G. Moffit. A mechanical time fuse for shells. April 19.

6614. W. Hurst. Improvements in the manufacture of wax matches, vestas, and tapers, and other similar goods. April 30.

6715. K. K. Malstrom. Improvement in percussion fuses. May 1.

6867. C. B. Levita. An improved percussion fuse. May 3.

7301. C. O. Lundholm and G. H. Hosie. Improvements in the manufacture of explosives. May 10.

7596. E. Turpin. Improvements in, and in apparatus connected with, the preparation and application of explosive substances for charging shells, torpedoes, mine cartridges, and the like. Complete Specification. May 15.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

1115. H. M. Chapman. Manufacture or treatment of explosives. May 14.

8718. Sir F. A. Abel and J. Dewar. Manufacture of explosives. April 30.

9361. A. V. Newton.—From A. Nobel. Preparation of explosives. May 7.

9433. W. B. McGavin.—From E. W. McGavin. Explosive compounds. April 30.

10,312. C. O. Lundholm. Manufacture of dynamite. May 14.

10,376. C. O. Lundholm and J. Sayers. Manufacture of explosives. May 14.

10,437. T. Parker and A. E. Robinson. Manufacture of phosphorus. May 7.

12,249. J. C. Butterfield and T. C. Batchelor. Explosive cartridges. May 21.

1890.

4243. W. Schuckher. Grained smokeless explosive. May 7.

# THE JOURNAL

OF THE

# Society of Chemical Industry:

## A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 6.—Vol. IX.]

JUNE 30, 1890.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.]

## The Society of Chemical Industry.

### Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond	1888—1889.

## COUNCIL FOR YEAR ENDING JULY, 1890.

*President: Sir Lowthian Bell, Bart., F.R.S.*

### Vice-Presidents:

R. Forbes Carpenter.	S. H. Johnson.
Prof. F. Clowes, D.Sc.	Ludwig Mond.
Sir J. Neilson Cuthbertson.	Dr. Hugo Müller, F.R.S.
Prof. James Dewar, F.R.S.	Dr. W. H. Perkin, F.R.S.
Jas. Duncan.	Dr. Edw. Schunck, F.R.S.
Dr. John Evans, F.R.S.	Prof. W. A. Tilden, F.R.S.

### Ordinary Members of Council:

L. Archbutt.	B. E. R. Newlands.
S. B. Boulton.	Jno. Pattinson.
Jno. Brock.	Jno. Spiller.
Jno. Calderwood.	E. C. C. Stanford.
Alexander M. Chance.	J. C. Stevenson, M.P.
A. E. Fletcher.	A. Norman Tate.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

*E. Rider Cook, East London Soapworks, Bow, E.*

### Honorary Foreign Secretary:

*Dr. Ferdinand Hurter.*

*General Secretary: Charles G. Cresswell.*

### Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

## THE JOURNAL.

### Publication Committee:

#### The President.

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	Ivan Levinstein.
Joseph Bernays, M.I.C.E.	Prof. R. Meldola, F.R.S.
H. Brummer.	Ludwig Mond.
W. Lant Carpenter.	E. K. Muspratt.
Prof. Frank Clowes, D.Sc.	B. E. R. Newlands.
W. Y. Dent.	C. O'Sullivan, F.R.S.
Prof. Jas. Dewar, F.R.S.	John Pattinson.
John Heron.	W. H. Perkin, Ph.D., F.R.S.

## NOTICES.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those Members of Council whose names are placed in italics in the annexed list will retire from their respective offices at the forthcoming Annual General Meeting.

Mr. E. Rider Cook has been nominated to the offices of President and Treasurer; and Sir Lowthian Bell, Bart., F.R.S., has been nominated Vice-President under Rule 11.

Mr. David Howard, Mr. B. E. R. Newlands, and Mr. J. C. Stevenson, M.P., have been nominated Vice-Presidents under Rule 8; and Mr. R. R. Tatlock and Mr. T. W. Stuart have been nominated Ordinary Members of Council under Rule 17, in the place of Mr. B. E. R. Newlands and Mr. J. C. Stevenson, M.P., nominated Vice-Presidents.

The Foreign Secretary has been nominated for re-election.

Mr. Alfred H. Allen, Mr. John R. Ashwell, Mr. H. Grimshaw, Professor R. Meldola, F.R.S., Mr. E. K. Muspratt, Mr. T. L. Patterson, and Mr. Boverton Redwood have been nominated, under Rule 18, to fill four vacancies among the Ordinary Members of Council.

## ANNUAL GENERAL MEETING.

Notice is hereby given that the next Annual General Meeting will be held in Nottingham on Wednesday, Thursday, and Friday, the 9th, 10th, 11th July next.

The following is a synopsis of the arrangements:—

## Wednesday, July 9th.

- |  |   |                     |
|--|---|---------------------|
| 1. Annual Meeting, University College  | - | 11 a.m.             |
| 2. Midland Railway Works, Derby; train leaves Nottingham   | - | 1.10 p.m.           |
| Or, Messrs. Morley's Hosiery Factory, Messrs. Turney's Leather Works, Messrs. Blackburn's Hosiery Machine Works, and Messrs. Lindley, Wright, and Cox's Lace and Hosiery Finishing Works | } | 2.30 p.m. to 4 p.m. |
| 3. Conversazione at Nottingham Castle  | - | 8 p.m.              |

## Thursday, July 10th.

- |  |   |                       |
|--|---|-----------------------|
| 1. The Burton Breweries; train leaves Nottingham   | - | 9.50 a.m.             |
| 2. The Butterley Iron Company; train leaves Nottingham   | - | 1.25 p.m.             |
| Or, The Birks Company's Embroidery Works, Messrs. Manlove's Engineering Works, The Nottingham Company's Hosiery Factory, and Messrs. Dobson's Lace Factory   | } | 10 a.m. to 11.30 a.m. |
| And Messrs. Lambert's Lace Dressing Rooms, The Midland Lace Company's Prilling Factory, Messrs. Doughty's Lace Factory, and Messrs. Morley's Hosiery Factory | } | 2.30 p.m. to 4 p.m.   |
| 3. The Dinner at the Exchange Hall   | - | 7.30 p.m.             |

## Friday, July 11th.

- |   |   |           |
|---|---|-----------|
| Excursion to Welbeck Abbey and Clumber; train leaves Nottingham | - | 8.20 a.m. |
|---|---|-----------|

Tickets of membership will be found with the Ballot Lists in this number of the Journal.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

## LIST OF MEMBERS ELECTED, 23rd JUNE, 1890.

- Baly, E. C. C., Bank of England, E.C., chemical student.  
 Banks, Jno. H., East 49th Street (corner 4th Avenue), New York, U.S.A., mining engineer.  
 Bradley, Edw. F., The Star Brush Co., Lim., Eden Grove, Holloway, N., engineer.  
 Bryce, Jno. Annan, Messrs. Wallace Bros., 8, Austin Friars, London, E.C., merchant.  
 Chorley, Jno. C., Lodge Lane, Bewsey, Warrington, chemical student.  
 Claypole, Dr. E. W., Buchtel College, Akron, Ohio, U.S.A., professor of natural science.  
 Crowder, S., Hillside, Auckland Road, Upper Norwood, S.E.  
 Ellershausen, Francis, Hebburn-on-Tyne, alkali manufacturer.  
 Foster, Jas., Baltic Chambers, Sunderland, consulting engineer, M.I.M.E.  
 Griffin, Jno. R., 22, Garrick Street, Covent Garden, W.C., chemical apparatus maker.  
 Halls, Claude W. G., 5, Carter Gate, Newark, Notts., chemical student.  
 Harmon, Lawrence E., c/o Edw. Elsworth, 71, Park Place, New York, U.S.A., analyst.  
 Heape, Chas., 19, George Street, Manchester, calico printer.  
 Hewlett, Jno. Cooke, 40—42, Charlotte Street, Great Eastern Street, E.C., manufacturing chemist.  
 Holmes, Geo. H., 9, Regent Street, New Basford, Nottingham, lace merchant.  
 Irving, Jos., Minas de Azualc6llar, Province de Sevilla, Spain, chemist.  
 Jarnain, Geo. Sales, Croft House, Marsh, Huddersfield, wool extractor.  
 Lord, Fred J., 150, Yorkshire Street, Rochdale, chemical student.  
 Mordle, F. Dare, Holloway House, Highbury Vale, Nottingham, starch manufacturer.  
 Nahusen, Dr. Rudolf, Hayle, Cornwall, technical manager, National Explosives Co., Lim.  
 North, E. Gordon N., Bella Vista, 14, Minas de Rio Tinto, Huelva, Spain, chemist.  
 Penn, Alf. Edw., 40, Westbury Street, Wandsworth Road, London, S.W., engineer.  
 Potter, E. C., 13, Circus Street, Greenwich, S.E., manure works chemist.  
 Selby, Wm., 113, Willoughby Street, Lenton, Nottingham, brewer.  
 Shaw, Herbert D., Castle Mount, Sandal, near Wakefield, analytical chemist.  
 Stillman, Dr. Thos. B., Stevens Institute of Technology, Hoboken, N.J., U.S.A., professor of analytical chemistry.  
 Sutherland, Alex., Ballynure-by-Ballyclare, co. Antrim, Ireland, mining engineer.  
 Taylor, Leo, Beechfield, Copeland Road, Walthamstow, E., analytical chemist.  
 Tompkins, H. K., 40, Torriano Avenue, Camden Road, N.W., chemist.  
 Twedy, Jas., 77, Western Road, Jarrow-on-Tyne, chemist and assayer.  
 Vult6, Hermann T., School of Mines, Columbia College, New York, U.S.A., assistant in analytical chemistry.  
 Wheeler, Wm. E., Cumberland House, Meynell Road, South Hackney, N.E., colour chemist.  
 Wilson, Alf., c/o Messrs. Jno. and E. Sturge, 18, Wheelleys Lane, Birmingham, chemical manufacturer.

## CHANGES OF ADDRESS.

Alexander, J. O., 1/o Demerara; 6, Sussex Terrace, Plymouth.

Bamber, H. K., Journals to 9, Victoria Street, Westminster, S.W.

Briggs, Wm., 1/o Arbroath; 4, Erskine Terrace, Dundee.

Carran, T. W., 1/o Shiel Road; 12, Rawlins Street, Liverpool.

Colby, W. H., 1/o Denbigh; Carregiven, Aberystwith.

Craw, Jno., 1/o Paisley; 15, Cadogan Street, Glasgow.

Eastlake, A. W., Journals to 17, Temperley Road, Balham, S.W.

Follows, F. W., 1/o Fairfield; Gorton, Manchester.

Gillman, Sr. Don Gustavo, 1/o Granada; Cantoria, Prov. de Almeria, Spain.

Hindle, J. H., 1/o Avenue Parade; 8, Cobham Street, Acerington.

Hunton, H., Journals to Greystone, Carlton, Ferryhill, co. Durham.

Laurie, A. P., 1/o Mile End Road; King's College, Cambridge.

McCulloch, Jas., 1/o Hebburn; Oakleigh, Rose Street, Garnet Hill, Glasgow.

Newton, H., 1, Glegg Street (not Slegg Street), Macclesfield.

Prinz, Dr. Otto, 1/o Schwarzenburg; Markt Redwitz, Bavaria.

Rademacher, H. A., 1/o Ohio; c/o Perkins, Goodwin, and Co., 66, Duane Street, New York, U.S.A.

Rideal, Dr. S., 1/o Forest Hill; Chemical Laboratory, St. George's Hospital, London, W.

Shearer, A., 1/o Boake and Co.; The Laboratory, 8, Hamfrith Road, Stratford, E.

Steedman, R. H., Journals to Sprengfield House, Dalnair, N.B.

Walsh, P. H., 1/o Cineionati; 13, Penny Street, Blackburn.

Williams, W. Collingwood, 1/o Grove Street; 44, Mulgrave Street, Liverpool.

Wright, J. C., 1/o Eglinton Street; Fern Bank, Irvine, N.B.

## CHANGES OF ADDRESS REQUIRED.

Kent, W. H., 1/o The Lodge, Buhmershe Road, Reading.

Manby, Eardley B., 1/o Halliwell, Bolton-le-Moors.

Walker, Jas. S. H., 1/o Morningside Road, Edinburgh.

## Deaths.

Lord Magheramorne, 17, Grosvenor Gardens, S.W.

A. E. Smith, Widnes, Lancashire.

## London Section.

## CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: David Howard.

## Committee:

Sir P. A. Abel.

H. E. Armstrong.

W. Lant Carpenter.

W. Crowder.

W. J. Dibdin.

C. Graham.

S. Hall.

C. C. Hutchinson.

R. Messel.

B. E. R. Newlands.

B. Redwood.

T. Royle.

John Spiller.

Wm. Thorp.

C. R. Alder Wright.

Hon. Local Sec. and Treasurer: Thos. Tyrer, Battersea, S.W.

The names in Italics are those of members of Committee who retire at the end of the current Session.

The following have been elected to fill the vacancies and will take office in July next:—Chairman: T. Tyrer; Secretary: T. W. B. Mumford; Committee: J. Dewar, A. G. Green, C. W. Heaton, D. Howard, W. S. Squire, T. E. Thorpe.

## SESSION 1889-90.

1890.

July 9th, 10th, and 11th:—Annual General Meeting in Nottingham.

Meeting held on Monday, June 2nd, 1890.

MR. DAVID HOWARD IN THE CHAIR.

ON THE RESISTANCE OF OILS AND RESINS  
TO THE PASSAGE OF MOISTURE.

BY A. P. LAURIE, M.A.

THE experiments of Captain Abney and Professor Russell on water-colours have shown that many pigments fugitive under ordinary conditions are permanent in dry air, though exposed to sunlight. It is therefore of importance to know what mediums used for painting protect a pigment absolutely from moisture, and what allow moisture to pass through. This is of special importance in the painting of pictures when durability is required, but may also have some bearing on the commercial use of oils and resins to protect surfaces. My attention was the more directed to this subject, as I found receipts in 15th century MSS. for the preparation of such fugitive colours as Brazil wood lakes, which must, to account for the remarkable state of preservation of pictures by the old masters, have been carefully locked up from moisture. I determined therefore on some experiments to discover how far ordinary oils and varnishes could be held to protect a pigment from the action of moisture.

With a view to testing this, I ignited pure sulphate of copper, obtaining the white anhydrous sulphate. Using this as a pigment, I ground it with oil and painted it out on three glass slides. One I exposed to the air near an open window, one on the mantel-piece of a warm room, and one I placed in a desiccator. In 12 hours, the slide near an open window was green, the slide in the warm room was slightly green, and the slide in the desiccator was still white. On now exposing all three to the air near the window, they all turned completely green in another 12 hours. I had evidently here a delicate method of testing the permeability to moisture of such vehicles. I therefore experimented as follows:—The sulphate of copper having been ground with the vehicle to be tested, and painted out on a glass slide, it was next placed in a desiccator to dry.

When quite hard, it was then either placed under a bell-jar containing a dish of water or exposed to the air of the room. In most cases a duplicate slide was made and was kept in the desiccator for comparison. It would be tedious to recount all the experiments, and I merely give the results.

I first compared pale boiled oil, best copal oil varnish, amber dissolved in oil, amber dissolved in turpentine, common rosin in turpentine, and mastic in turpentine.

The amber in turpentine remained unchanged.

The other turpentine varnishes turned an opaque bluish-green.

The oil and oil varnishes turned a transparent pale green.

On next examining these slides under the microscope, a curious difference presented itself. In the case of the oil and oil varnishes, a uniform change had taken place, the copper sulphate being apparently completely hydrated, and here and there perfect crystals of sulphate of copper could be seen.

In the case, however, of the turpentine varnishes, the surface consisted of planes of unaltered sulphate, with cones of sulphate of copper crystals rising here and there on the surface, making the whole surface rough as seen under the microscope. In only one case out of three the amber in turpentine showed a similar appearance over part of the surface.

Apparently then, the resins when dissolved in a volatile oil, do of themselves protect the sulphate of copper from moisture, but tend to form holes and cracks through which moisture enters. Amber in turpentine, however, seems to be free from this tendency. On the other hand, linseed oil, whether mixed with resins or not, seems to be permeable to moisture over the whole surface with such completeness as not to cause the formation of rough projections of crystals.

It next seemed of importance to test how far the linseed oil when dry could be protected by coating with a resin dissolved in turpentine. I therefore prepared slides with linseed oil, and when dry, coated with (1) amber in turpentine, (2) copal in turpentine, (3) mastic in turpentine, (4) copal in oil. After drying and 12 hours' exposure to moisture, (1) and (2) were covered with green spots, but (3) and (4) unchanged. Under the microscope these spots were round in outline with sulphate of copper crystal cones filling them. In three or four days all the slides were green. Apparently, then, a resin in turpentine does not protect linseed oil, and the better the resin the more likely it is to be pulled into holes, doubtless owing either to capillary forces, or to different expansions of the two layers.

It seemed next of some importance to decide how far the preparation of the linseed oil would affect the result. I therefore obtained the best seed, had it picked over, cold pressed, refined over water in sunlight, and converted into boiled oil with borate of manganese. In some of this oil I dissolved amber, and in some copal. I also had a very fine specimen of commercial copal varnish, and two good samples of commercial boiled oil, Meguill, an artist's medium from a good maker, another pure linseed oil slightly differently prepared. These I tested in various ways, sometimes mixing a little varnish with the oil, sometimes using the varnish pure, sometimes allowing the slide to dry, then varnishing with the same medium and drying again before exposure.

None of these combinations resisted the action of moisture, nor did they differ greatly in the rapidity with which the change took place. On the whole the pure oil usually stood longer than the commercial oil, and the presence of a little varnish, especially amber varnish, seemed to preserve it a little longer still; but the results were uncertain, the method not lending itself well to comparative tests of this kind, as the thickness of the layer of oil of course affects the result.

One result of interest was, however, obtained, and that was that the power of linseed oil to resist moisture is immensely improved by keeping the slide for some time after the oil is dry, every week in the desiccator improving it in this respect.

As far, then, as the evidence goes, resins in volatile oils resist the passage of moisture in themselves, but tend to become full of holes and cracks, amber resisting best in this respect.

No vehicle containing linseed oil resists the passage of moisture unless possibly by long keeping. (This point is under examination.)

If such painters as Van d'Eyck had a medium which protected colours from moisture as apparently, judging from their pigments and pictures, they had, it remains to be discovered.

The method should prove useful in testing preparations meant to absolutely protect surfaces from moisture, with a view to finding how far they may be trusted to do so.

## A NEW EXPOSURE METER.

BY ALFRED WATKINS.

THIS instrument which I have invented for the calculation of photographic exposures is a combination of—1. an actinometer, for which I use a bromide paper sensitised with nitrite, according to Captain Abney's suggestion. II. a chain pendulum, beating half seconds. III. a set of calculating slide rules arranged so as to be worked in a mutually dependent series. The instrument deals with the several factors of photographic action in order, to each being appropriated a graduated brass ring, moving independently but in a common axis. These factors are

A the actinic force of the light falling upon the worst lighted part of the subject. P the sensitiveness of the plate used. S the capacity of the subject for reflecting the actinic rays. D the size of diaphragm, *i.e.*, its ratio to the focal length of the lens. These factors are reduced to numerical expression in a series of values representing their influence severally and independently upon the photographic action: the rings are graduated in terms of these values. The interdependence of these values is established on a basis which is necessarily empirical and to some extent arbitrary; this I have fully discussed in a paper read before the Hereford Photographic Society and published in the *British Journal of Photography* (April 18th and 25th, 1890). On this occasion I merely wish to call the attention of the Society to the instrument itself and to the photographs which I produce as evidence of the trustworthiness of its indications. The prints are from four negatives as follows:—

	Subject.	Duration of Exposure.
a.	Cloud picture.	$\frac{1}{2}$ second.
b.	Landscape.	4 seconds.
c.	Interior.	8 minutes.
d.	Interior (dark oak).	45 minutes.

the negatives being developed simultaneously in the same solution.

## DISCUSSION.

THE CHAIRMAN said that the question of correct exposure was one of vital importance to the practical photographer; and though the use of the little instrument now before them might render unnecessary much of the skill at present shown in the development of photographs, it might still, he thought, be well to substitute scientific certainty for that personal

skill which was at present shown by many artists in correcting the mischief done by inaccurate exposure. He understood that by the use of the apparatus now introduced to them photographers could rely on getting accurate exposures and thus greatly reduce the difficulties of development.

At the conclusion of the ordinary business of the meeting, Mr. W. THORR moved and Mr. S. HALL seconded the following resolution: "That the best thanks of the members of the London Section be and are hereby tendered to its Chairman, Mr. David Howard, for his close attendance in the chair and his courtesy in its occupation for the last six years."

The resolution was carried by acclamation.

Mr. HOWARD suitably replied.

Dr. L. T. THORNE then moved—"That the heartiest thanks of the members are due, and are hereby tendered, to Mr. Thomas Tyrer for his able conduct of the secretaryship of the London Section since the formation of the Society in 1881."

The resolution was seconded by Mr. DAVID HOWARD, who in doing so referred to the fact that Mr. Tyrer would succeed him in the chairmanship of the Section in the next session. This resolution also having been carried by acclamation,

Mr. TYRER replied.

#### DISCUSSION ON MESSRS. CROSS AND BEVAN'S PAPER ON THE CHEMISTRY OF HYPOCHLORITE BLEACHING. (This Journal, May 1890, 450.)

The CHAIRMAN said that modern science had no doubt made bleaching apparently effectual; but those who had had an opportunity of studying the wonderful collections of linen made by our grandmothers and great-grandmothers when they began housekeeping, were bound to confess that in these days one could not for love or money get new linen of similar quality. The fatal facility with which bleaching could be effected by bleaching powder had tempted the users thereof to ignore the fact that the process was not so simple as it appeared at first sight, and the thanks of the meeting were due to the authors for calling attention to the complexities of the process of bleaching. The authors had, he thought, shown an unnecessary amount of modesty in apologising for the incompleteness of their paper. It was not in the nature of things that such a paper could be perfect unless the authors had studied completely all the forms and data of bleaching. He agreed with them that it was far more useful to study the methods of investigation than every possible application of them. It was only by the minute study of the progress of the decompositions which occurred during the process of bleaching that each user of the agents employed could decide what was best suited for his own particular purpose.

Dr. L. T. THORNE said that the paper abounded with points of great scientific and practical interest. He was unfortunately unable to follow the authors in some of their theoretical and experimental considerations, having been obliged up to the present time to confine his attention rather to the practical side of the question, and to leave to a later time the elucidation of several points of great interest which he had noticed in watching the ordinary operations of bleaching. There were two or three points, however, to which he would like to refer in connexion with Messrs. Cross and Bevan's work. In the first place, referring to their suggestion that the loss of chlorine was possibly due to the formation of chlorinated organic compounds of low atomic weight, it seemed to him highly probable that

such compounds were formed, especially in the earlier stages of the process. In all bleaching houses it was well known that chlorine compounds came off, and in watching carefully the bleaching of pulps such as were used for newspaper, he had himself noticed that when the bleaching had just begun, at the point when the change was most rapid, there was a very pungent odour, undoubtedly chlorinous in character, but equally undoubtedly due to something beyond chlorine or an oxide of chlorine. He was inclined to think that it was not even simple chloroform, but rather some other organic chlorine compound. Of course further complications arose from the fact that large quantities of either simple chlorine or its derivatives were liberated at the same time. That fact was clearly brought out in the course of his own experiments in passing air through pulp while undergoing the process of bleaching. The large quantities of nitrogen which passed away were found to be strongly impregnated with chlorine, and more bleaching powder was required when air was passed through than when no air was employed, though the oxygen of the air was used up, and so tended to reduce the quantity of chlorine required. Again, he thought that the presence and reactivity of the ketonic groups had much to do with bleaching. Experiments in which he had used oxygen in conjunction with bleaching powder, seemed clearly to show that such was the case. Oxygen alone did not cause any great amount of bleaching effect, but when used in conjunction with bleaching powder it showed a very marked effect. That, he thought, was undoubtedly due to its action on the aldehydic and ketonic groups existing in the compound celluloses or formed as intermediate products. The percentage of base in bleaches was another point of great importance. The way in which weak bleaching solutions were made from partially exhausted lime sludge was very questionable; in fact, the way in which the whole process of bleaching was often carried on was open to great improvement. There was, altogether, too much rule of thumb. Bleachers did not seem to consider that if they treated their partially extracted sludge with water there was a possibility that they might get a solution of a different character from that at first used. One point struck him as curious in connexion with the experiments dealing with the quantity of base not reverting to chloride, and that was the difference found in the magnesium hypochlorite made by double decomposition, as compared with that obtained by the electrolytic method. For whereas, as was shown on the board, from 13 to 16 per cent. of the former did not revert to chloride—i.e., 13 to 16 per cent. of chlorine acted in some way or other in a chlorinating manner—in the case of the latter there was no reversion whatever. That was a very curious difference, and he would like to know whether Messrs. Cross and Bevan had formed any opinion as to its cause. Chlorination was a most important point in the process of bleaching, and one that had been hitherto almost completely disregarded. He thought that the non-permanency of many bleached substances was largely due to that disregard of chlorination compounds, and that when bleaching was carried on under different conditions, the chlorination and the final result would be different also. The authors had shown that at a low temperature chlorination took place to a less extent than at a high temperature; and everyone who had experience of bleaching on a large scale well knew that when the process was carried on at a low temperature—at a sacrifice of some amount of time—the pulp obtained was more permanent in character, and had not that tendency to "go back" which was generally shown by pulps bleached at higher temperatures. We were now living in a time of high pressure, and the practical bleacher wanted to get as much pulp bleached in a day as possible. To that end, he pushed on his bleaching by means of high temperatures, in some cases working at 120° F. He got his bleaching done quickly, but there was a larger consumption of bleaching powder, and if he left his pulp for a short time—say 10 or 12 hours—before working it up, there would generally be a marked tendency to "go back." That effect was also due to the difference of action and chlorination of which he had already spoken; in fact, one of the most important points in bleaching was the avoidance, as far as possible, of that

strong chlorination of the cellulose compounds. Such a course was absolutely necessary in order to produce a good sound paper that would keep its colour, and at the same time not exercise that deleterious action on artistic colours which one heard so much about, and also to avoid a tendering effect on the paper itself. The actual isolation of the organic chloride was of great interest, as proving beyond doubt its presence in some of the bleached pulps. Altogether, the paper just read opened up a great many lines of thought, and would, he expected, be of great value, not only to scientists, but to practical bleachers; and if followed up should produce an improving effect on the bleaching of the future.

Mr. C. F. CROSS, in reply, reminded Dr. Thorne that he had expressly stated in reading the paper that he refrained from dealing with the question of bleaching efficiency; but Dr. Thorne having asked a question with respect to the difference in this respect of the magnesium hypochlorite prepared in the ordinary way and by the electrolytic method, he could state that nothing was more striking than the difference in the action of the two solutions in that particular ease. It was not only that the results shown by the numbers for proportion of residual base were obtained, but, if he might be allowed to use the expression, he would say that the electrolysed solution simply "went to pieces" on those particular pulps. It was exhausted with extreme rapidity, and to all appearance and up to a consumption of 3 percent. of chlorine produced no bleaching effect whatever. Upon well boiled pulps the reverse effect resulted; the electrolysed solution getting to work with much greater rapidity and effecting a considerable economy of chlorine. It would appear that chlorination of the pulp constituents was an advantage in one case and not in the other. This opened up a question which, as Dr. Thorne would see, could only be touched upon in the paper just read, namely, as to whether chlorination was not an essential factor in certain bleaching in *breaking down* the molecules. It was possible that chlorination might act in breaking down and resolving those complex ketonic bodies, and the resulting products become saponified in the after process, and so the effect of chlorination might not be evident from the study of the final products. Such points as these, however, would require special and very careful study. Mr. Bevan and he had aimed at but little more than indicating in their paper a general method of proceeding which, if followed up by other workers would, they hoped, in time result in a common understanding. If those interested in the subject would take the method in hand and make their own quantitative observations, it would not be long before they would have an important contribution, not only to practical bleaching but to theoretical chemistry. He knew that people in the habit of dealing with tons and gallons were apt to "shy" when talked to about molecular problems, and object to what they are pleased to call "long words." Investigators could not be always apologising for terms necessitated by the progress of science. If those who understood both the theoretical and practical sides of the question would agree (or even disagree) with them, and at least arrive at a common understanding as to the best way of thoroughly investigating this widely extended subject and analysing it down to its last terms, the object of their work would have been attained.

may be stated that in this new lamp the novelty is the simultaneous and corresponding regulation of the admission of gas and air to Bunsen burners. To this end the short vertical tube or jet used in ordinary Bunsen burners for the admission of gas into the outer tube (the lamp) is dispensed with, and the burner—or outer—tube is made to act as a regulating cock both for gas and air.

In order thus to serve as a regulating cock the extremity of the burner tube tapers to a conical shape, and is ground so as to fit the tube forming the base of the lamp and containing the air-holes so as to form in it a kind of plug cock, as a stopper does in the neck of a bottle. The gas enters the piece of metal tube, fixed at right angles to the burner tube, but at its extremity directly enters the burner by a horizontally disposed orifice, which on turning the burner tube is gradually closed. This arrangement obviates the objectionable "firing-back" of the flame when the supply of gas is reduced. Mr. Watson Smith's additions consist (1) in a telescope tube G, fixed around the burner tube of the ordinary lamp C, the effect being to make possible the raising or lowering of the position of the lamp-flame at will (*vide C''*); (2) in a hinge arrangement at the base, such that the lamp-tube may be inclined at any angle (as at C'), or placed in a perfectly horizontal position if desired; (3) in a cylindrical brass perforated shield placed around the base containing the air-holes, so that by revolving this around the base the air-holes are either gradually and at last entirely closed, or gradually and at last entirely opened, as the case may be, and with ease; and (4) in the addition of a gallery with chimney E, for protecting the flame. No. 2 addition is most especially useful in the process of soldering, or in the burning of filters over glazed paper in gravimetric analysis, &c. The telescopic arrangement (No. 1) is found very useful in fractional or ordinary distillations.

#### NEW AND IMPROVED FORM OF BUNSEN'S BURNER.

MR. J. R. GRIFFIN exhibited some new forms of Bunsen's lamp. The first, A, was the invention of G. Reimann, of Berlin, Eng. Pat. 20,744 of December 24, 1889, the others were modified forms of Reimann's lamp made by Mr. Griffin's firm (J. R. Griffin and Sons) at the suggestion of Mr. Watson Smith, and with the consent of Herr Reimann. Briefly it

The names in *Italics* are those of members of Committee who retire at the end of the current Session. The following have been selected to fill the vacancies, and will take office in July next:—  
Chairman: E. C. C. Stanford; Vice-Chairman: A. Crum Brown; Secretary: G. G. Henderson; Treasurer: W. J. Chrystal; Committee: W. J. A. Donald, C. A. Fawcitt, J. Falconer King, T. P. Miller, J. Pattison, and R. R. Tatlock.

### SESSION 1890.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Meeting held in the Societies' Rooms, 207, Bath Street, Glasgow, on Tuesday, 3rd June 1890.

MR. J. PATTISON IN THE CHAIR.

## ON TRANSVAALITE—A NEW COBALT MINERAL.

BY THOS. B. MCGHIE AND JOHN CLARK, PH.D.

IN 1889 Mr. McGhie, who had occasion to be in the Transvaal, took the opportunity of paying a visit to a cobalt mine about 30 miles north of Middleburg, and brought away with him a number of specimens.

The ore of this mine, which consists essentially of arsenide of cobalt or smaltine, occurs in a vein of quartzite, and was worked for several years, when it was abandoned, owing, probably, to the cost of transit and the difficulty of separating the ore from its matrix.

A sample of this ore was found on analysis to have the following composition:—

	Per Cent.
Arsenide of cobalt .....	57.39
Arseniate of cobalt .....	8.27
Sulphide of cobalt .....	1.02
Sulphide of nickel .....	0.38
Sulphide of iron .....	None.
Siliceous matter .....	30.55
Combined water .....	1.46
Moisture .....	0.52
	<u>99.59</u>

From the above analysis it will be observed that the ore itself, apart from the matrix, is remarkably pure, but although the vein at some parts is several inches in thickness, the greater part of the ore is distributed throughout the matrix in such a manner that it can only be separated by washing appliances.

The specimens on the table show the appearance of the ore at different parts of the vein.

In the same rock, at a short distance from the vein of arsenide, there is another vein of a different kind of cobalt

ore, varying in width from about 2 inches to a thin streak, which, we understand, was followed for a short distance in search of gold, and then abandoned. This is the mineral which forms the subject of our communication. Where the vein is wide the ore is black in colour, with reddish-brown patches, and somewhat nodular in its external appearance, but where the vein is thin the ore is black, and has a slaty fracture. It dissolves in hydrochloric acid readily, with the evolution of a great deal of chlorine, and gives a solution which is bluish-green when concentrated, but pink when diluted.

The nodular portion, of which I show you a specimen, and of which the greater part of the sample was composed, was found on analysis to have the following composition:—

	Per Cent.
Sesquioxide of cobalt .....	65.80
Protoxide of cobalt .....	3.82
Oxide of nickel .....	0.15
Arsenic acid .....	5.79
Sesquioxide of iron .....	2.41
Alumina .....	2.68
Manganese dioxide .....	None.
Lime .....	0.40
Magnesia .....	0.30
Sulphuric acid .....	..
Silica .....	6.35
Water .....	<u>12.19</u>
	<u>99.89</u>

	Per Cent.
Cobalt .....	49.54
Specific gravity .....	3.846
Hardness .....	4.0
Streak .....	Brownish black.
	Per Ton.
Gold .....	1 oz. 12 dwt.

The percentage of sesquioxide of cobalt was determined from the chlorine evolved by heating with HCl, and found to be equivalent to 6.42 per cent. of oxygen, which has been assumed to be in the form of  $\text{Co}_2\text{O}_3$ , and the water was ascertained by igniting a weighed portion of the mineral and deducting the oxygen given off from the loss.

The results which we have obtained indicate that this mineral is essentially a hydrated sesquioxide of cobalt with 7.72 of arseniate of cobalt ( $3\text{CoO} \cdot \text{As}_2\text{O}_5$ ), and if the oxide of iron exists in the form of hydrated arseniate of iron, which is probably the case, there is just about enough arsenic acid remaining, after calculating the protoxide of cobalt to arseniate, to form  $2\text{Fe}_2\text{O}_3 \cdot \text{As}_2\text{O}_5$  (iron sinter).

3.82 of $\text{CoO}$ requires .....	3.90 $\text{As}_2\text{O}_5$
2.41 „ $\text{Fe}_2\text{O}_3$ „ .....	1.73 „
	<u>5.63</u> „

With the exception of wad, or earthy cobalt ore, which is regarded as consisting essentially of  $\text{CoO}$ ,  $\text{MnO}_2$ , the only known cobalt mineral which so far as we are aware resembles Transvaalite is Heubachite, a natural hydrated oxide of cobalt and nickel, described by F. Sandberger in 1877 (Journ. Chem. Soc., Vol. II., p. 855) as having the following composition:—

	Per Cent.
$\text{CoO}$ .....	65.50
$\text{NiO}$ .....	14.50
$\text{Fe}_2\text{O}_3$ .....	5.13
$\text{MnO}_2$ .....	1.50
$\text{H}_2\text{O}$ .....	<u>12.59</u>
	<u>99.22</u>
Specific gravity .....	3.44
Hardness .....	2.5

Heubachite is found in extremely thin soot-like deposits in clefts in barytes, and is said to evolve a good deal of chlorine with HCl. The cobalt is nevertheless represented by Sandberger as existing entirely in the form of protoxide of cobalt ( $\text{CoO}$ ), and, if the analysis is correct, this mineral

cannot contain more than a small quantity of sesquioxide of cobalt ( $\text{Co}_2\text{O}_3$ ), and it differs essentially from Transvaalite by containing manganese and a large proportion of oxide of nickel but no arsenic acid. It is also considerably lower in specific gravity and hardness. The occurrence of Heubachite is attributed to the action of water which contained the constituents of the mineral in the form of carbonates, and we think it is possible that Transvaalite has been produced in a similar manner. The occurrence of arsenide and arseniate of cobalt in the same rock veined in exactly the same way, combined with the presence of arseniate of cobalt in the Transvaalite, has led us to consider whether that mineral might not be a product of the decomposition of the arseniate of cobalt, and for this purpose we have analysed the rock itself, which in the neighbourhood of the vein is white, with here and there a brown film of oxide of cobalt, but at other places it contains purple patches of arseniate of cobalt.

#### ANALYSIS OF THE ROCK.

	Ignited Rock.
	Per Cent.
Silica.....	82.20
Alumina .....	11.40
Oxide of iron.....	Trace
Lime.....	..
Magnesia.....	..
Potash .....	0.60
Soda .....	0.04
Oxide of cobalt.....	2.80
	100.04
Loss on ignition .....	0.72

With the exception of the potash, there is nothing in the rock which would be likely to decompose the arseniate of cobalt, and the quantity is so small that we do not feel justified in concluding that the mineral has been formed from the arseniate by the action of the alkali of the rock and atmospheric influences; but at the same time there are so many circumstances in favour of this theory, that we think it is only proper to mention it as a possible method of formation.

#### DISCUSSION.

Dr. CLARK, in reply to questions, said he quite appreciated the view of those who looked at this mineral not from the scientific but from the commercial standpoint. He understood that the mine was a very long distance from the coast. The carriage some time ago was about 14*l.* per ton, but even 14*l.* should not interfere with its utilisation, as he supposed a mineral of this kind was worth more than twice that sum. The rock had apparently been worked for a short time, more with the view of getting gold than cobalt, and the Cobalt Company who opened up the mine evidently found that taking into account the carriage and difficulties of separation, &c. it would not pay, and the result was that a year ago the mine was standing idle. Even taking all this into consideration, however, he was satisfied that there was a sufficient quantity of the ore, with the present prices of cobalt and with proper machinery, to pay the cost of export to this country.

#### ON THE REVISION OF CONSTANTS EMPLOYED IN THE ANALYSIS OF FATS AND OILS.

BY R. T. THOMSON, F.I.C., AND H. BALLANTYNE.

THERE are certain chemical and physical constants, such as the iodine absorption and the specific gravity, which are of great importance in the analysis of oils and fats. In the present state of this branch of chemical analysis, the values assigned to these in books ought always to be revised

by chemists undertaking oil analyses. Our experience, at least, has been that while the specific gravities and alkali-neutralising powers of oils are as correct as the somewhat varied character of different specimens of the same oil will allow, the iodine absorptions of some oils are certainly understated.

But besides this, the ordinary arrangement of constants in books on oil analysis, as for instance in that useful collection of facts in Allen's "Commercial Organic Analysis," Vol. II., is not perhaps the most desirable. There is one table of specific gravities, another of potash-neutralisation equivalents, and a third in which the iodine absorptions are recorded. In such tables we have no means of knowing the relation between the different constants assigned to a given sample. Thus, we do not know whether an olive oil of low gravity has a higher iodine absorption than one of high gravity, or *vice versa*. Our second object, then, has been to give the specific gravity, potash-neutralisation equivalent, and iodine absorption of each specimen of oil tested. Of course it may be objected that other constants were not determined, such as Maumené's temperature test, but we have preserved the samples so that these and other values may be dealt with in a future paper.

Before proceeding further it may be noted that the results of our determinations are embodied in the accompanying table, in which the first point for consideration is the specific gravity of oils.

*Specific Gravity of Oils.*—The specific gravities which we have determined agree substantially with those already published, but allusion may here be made to the effect of the presence of free fatty acid in oils. It has been observed by Archbutt that olive oils of low density are high in free oleic acid. On this observation Allen has built the theory that 5 per cent. of free acid diminishes the specific gravity of the sample by 0.7. But this result is based merely on taking the highest density (917) observed by Archbutt as that possessed by pure olive oil, and assuming that variations in density are entirely due to free oleic acid. As a matter of fact such is not the case, as will be seen from the table, where an olive oil with 3.86 per cent. of free acid has a specific gravity of 914.8, while another with an almost identical density (914.7) contains 23.78 per cent., and yet another possessing a high specific gravity (916.8) contains as much as 5.19 per cent. of free acid. In the face of these results it is plain that no faith can be placed in the formula for altering the specific gravity of an oil according to the proportion of free acid contained in it. To make perfectly certain of this conclusion a sample of olive oil (sp. gr. 915.6) was treated with a solution of caustic potash in a separator, the soap solution run off, the oil washed with water and filtered through a dry filter. The density of the acid-free oil thus prepared was only 915.2, so that the free oleic acid (9.42 per cent.) appeared to have actually raised the specific gravity of the sample in the proportion of 0.2 for each 5 per cent. Free fatty acids prepared from the same oil had a specific gravity of 900.8 at 20.5° C. (compared with water at 15.5°), while the acid-free oil showed 911.8 at the same temperature. Assuming that the rate of expansion is the same for each, and that the fatty acids would be liquid at 15.5°, the specific gravity of the latter would stand at about 904. We have not had time to repeat these experiments with other oils, and confirmation is certainly desirable; but it would appear that we must not regard oils as mixtures of neutral oil with free fatty acid. This is consistent with theory, for it is generally conceded that high acidity is caused by the oil becoming rancid, or in other words, by the decomposition of the glyceryl oleate, etc. When this is taken into account it is not altogether surprising to find that the acid-free oil possesses a less density than the same oil after having become rancid.

*Potash-neutralising Power of Oils.*—There is nothing special to remark on this portion of the subject, except that our results are in unison with those of other observers.

*Iodine Absorption of Oils.*—Nübl's iodine absorption test seems to have almost entirely superseded the bromine absorption test, and it is in many cases the best datum on which the percentage of adulterant in any oil may be calculated, after the fact of adulteration has been proven

beyond doubt. It is therefore an imperative necessity to have this constant accurately determined. Hübl directed that absorption should be allowed to go on for two hours, but Archbutt has added to this two important suggestions: (1) that at least double the amount of iodine absorbed ought to be present; and (2) that the absorption should be allowed to go on for six hours. Our experience is that the first of these suggestions must be strictly adhered to, and that the second may be safely extended to at least eight hours. We have found that the absorption of iodine by lard oil is practically complete in about three hours, but that linseed and seal oils require fully eight hours. This will be apparent from the following table:—

RATE OF ABSORPTION OF IODINE PER CENT.

Time of Absorption.	Seal Oil.	Linseed Oil.
Two hours .....	136.6	175.5
Four hours .....	140.8	179.7
Six hours.....	145.1	184.1
Eight hours .....	145.8	187.7

When the time was extended to 18 hours no further absorption took place. In view of these facts we have found it a very good plan, to start the absorptions in the evening, and titrate the solutions on the following morning. A blank experiment should be made in every case with the chloroform and iodine solution employed.

As will be seen from the table appended, our results agree as a rule with those of Hübl, Moore, and Archbutt, given in Allen's "Commercial Organic Analysis," but in a few cases there are large variations. Thus, menhaden oil is given as 147.9, while our results show it to be as high as 160. Again, the highest recorded iodine absorption for raw linseed oil is stated at 160, while our results vary from 168 to 187.7 for different qualities of the oil. We have found two specimens of olive oil which show only 79 per cent. of absorption, this being 2.6 per cent. below the lowest recorded result, and one sample absorbing 86.4 per cent., which is 1.4 per cent. higher than any mentioned by Allen. It may also be noted here that iodine values calculated from Mills' bromine absorptions must not be accepted as correct for iodine, as seal oil, for example, is some 50 per cent. too low.

*Relation of the Constants to each other.*—If we examine the figures for lard given on the table, we find that the specific gravity is high when the iodine absorption is high, and *vice versa*. These lards were rendered by ourselves,

and can therefore be guaranteed genuine. We found that the whole of the lard contained in the portion of the pig operated upon had to be melted out before an average sample could be got. When only a portion was rendered, a soft lard was obtained, which had a high specific gravity and iodine absorption. The facts stated and observations made on other lards received for analysis go to show that these two constants have a definite relation to each other, and by interpolations we may arrive at the following relationship between the specific gravity and iodine absorption:—

TABLE OF RELATIONSHIP BETWEEN THE SPECIFIC GRAVITY AND IODINE ABSORPTION OF LARD.

Specific Gravity at 99° C. (Water at 15.5° C.= 1,000.)	Iodine Absorption.
	Per Cent.
859.8	52.1
859.9	53.4
860.0	54.7
860.1	56.0
860.2	57.3
860.3	58.6
860.4	59.9
860.5	61.3
860.6	62.5

This shows an increase of 1.3 per cent. for 0.1 increase in the specific gravity, and it will be observed that beef fat follows the same rule, as nearly as possible. Cotton-seed oil, the other adulterant of lard, would show only an increase of 0.6 per cent. of iodine absorption for an increase of 0.1 in specific gravity. These data may be utilised, if substantiated by other observers, in the analysis of lards, and especially of those samples containing cotton-seed oil which do not answer to the colour tests.

The only other oils of which series were tested were linseed, rape, seal, and olive oils, but the specific gravities and iodine equivalents of these do not appear to have any direct relationship. It is quite possible that a fuller examination of the relations between different constants may tend to throw considerable light on oil analysis, and this and other parts of the subject it is our intention to follow up.

TABLE OF CONSTANTS IN THE ANALYSIS OF OILS.

Nature of Oil or Fat.	Sp. Gr. at 15.5° C. (water at 15.5° = 1,000).	Sp. Gr. at 99° C. (water at 15.5° = 1,000).	Iodine Absorption.	KOH Neutralised.	Free Acid.

## DISCUSSION.

The CHAIRMAN said this was a paper which was difficult to lay hold of on hearing read, but he had no doubt that in print it would be very useful. Anything which gave information as to how to detect mixtures of oils was sure to prove valuable. He supposed that in regard to these constants one of the chief difficulties was to get pure samples of oil in order to form a basis. It seemed to be the practice for various reasons (not always to decrease the value) to mix oils.

Dr. CLARK asked if in giving the iodine absorption, the authors took samples of the whole fat of the pig or only of different parts, and whether they had done anything with the fat of the feet? There was considerable difference in the properties of the fat from different parts of the pig which affected the results very materially. When getting a sample of lard to examine, the great difficulty lay in ascertaining from what part of the pig the sample was taken. It might be the refuse from one part or it might be from the whole animal, so that the results must often of necessity

vary very much. As to the method adopted, however, it was an excellent one, and he was sure that the table given would be found very serviceable to public analysts, who had great difficulty in determining what was genuine and what was not.

Mr. BALLANTYNE, in reply to Dr. Clark, said that the first portion of lard rendered had a very high specific gravity and iodine absorption, and the portion rendered last had the lowest. They found that the lard from the omentum gave the lowest gravity and absorption, and that from the legs and ribs the highest, the latter of which were practically identical.

## THE PURIFICATION OF ARTIFICIAL SALICYLIC ACID.

BY G. G. HENDERSON, D.S.C., M.A., UNIVERSITY OF GLASGOW.

WITHIN the last few years the employment of salicylic acid, both as an antiseptic and for pharmaceutical purposes, has become very general, and the quantity of this substance manufactured for various purposes is now very considerable. There is a pretty large difference between the price of the "natural" acid obtained from oil of wintergreen or from salicin and that of the "artificial" acid synthetically prepared from phenol, and the natural result is that the artificial is used instead of the natural acid for many purposes. It has been observed, however, that the administration of the former (usually as a sodium salt) as a medicine is often followed by disturbances more or less severe, and sometimes of a grave nature, and it has recently been proved that these serious after-effects are due to the presence of impurities in the artificial acid and are not produced by use of the natural acid.

Professor Charteris of Glasgow University has carried out a series of comparative experiments on rabbits, using on one hand the natural acid and its sodium salt, and on the other hand a number of specimens of the artificial acid and its sodium salt which were obtained from various sources. The results of these experiments may be summarised as follows:—

Salicin, in 30-grain doses, natural salicylic acid, in 10-grain doses, and sodium salicylate (from the natural acid) in 32-grain doses, have no deleterious effect on rabbits weighing  $2\frac{1}{2}$  lb.

Artificial salicylic acid, in 10-grain doses, and sodium salicylate (from the artificial acid) in 18-grain doses, in ordinary use, cause the death of rabbits weighing  $2\frac{1}{2}$  lb. Even the very best specimens of the artificial acid (sold as "chemically pure"), in 15-grain doses, proved fatal to one rabbit, and in two others caused marked prostration and paralysis, but not death; while with less pure specimens a fatal result followed the administration of the acid in every case.

From these experiments it is evident that serious objections may be raised to the use of ordinary artificial salicylic acid for medical purposes, but the comparatively high price of the natural acid makes the production of a pure artificial acid very desirable. I therefore, at Dr. Charteris' request, made a number of experiments with the view of testing the possibility of so purifying commercial salicylic acid that it may be used with safety instead of the natural acid, and after trying various methods I find that the purification can be effected simply and economically by the process suggested by Williams some years ago (*Pharm. J.* 3rd S. 8, 785). A hot aqueous solution of the acid is neutralised with calcium carbonate and allowed to cool, when calcium salicylate, which is sparingly soluble in cold water, separates out in hard glistening crystals. When the best specimens of the commercial acid are used the crystals of the calcium salt are well formed and almost colourless, or only slightly tinged with brown, while inferior qualities of the acid yield a mass of indistinct brown crystals of the calcium salt. A further quantity of the salt, of course in a

more impure state, is obtained on concentration of the mother-liquor, and the greater part of the impurities is contained in the last mother-liquor, which is usually rather thick and of a dark reddish-brown colour. The calcium salt is recrystallised from hot water once, or oftener if necessary, and finally decomposed by hydrochloric acid, and the salicylic acid thus set free is washed with cold water and crystallised from dilute spirit. It is now obtained in large well-formed prismatic crystals, which are exactly similar in appearance to the crystals of the natural acid, and the melting point, solubility, and other properties of the two substances are exactly the same. The physiological action of the purified acid was investigated by Dr. Charteris with satisfactory results, for it was found that after administration of the acid in 15-grain doses there was "no paralysis, not even depression, after the last injection; rabbit able to run easily."

The impurities found in commercial salicylic acid are chiefly cresotic acid, which results from the use of impure phenol in the manufacture, parahydroxybenzoic acid, and hydroxyisophthalic acid. The presence of the two latter substances is due to the use of caustic soda containing potash or to undue raising or lowering of the temperature during the manufacture, as has been shown by Fischer in an interesting paper (*J. Pharm.* [5], 20, 258), in which methods for estimating the amount of the impurities in salicylic acid are also described. None of the specimens which I examined contained more than a very small quantity of impurity; this was separated from the last mother-liquor by addition of hydrochloric acid, conversion of the precipitated acids into calcium salts, and fractional crystallisation of the latter, and consisted principally of cresotic acid (m.p.  $151^{\circ}$ ). It was found that one grain of this impurity was sufficient to cause the death of a rabbit weighing 2 lbs.

It is troublesome to detect the presence of the impurities in the better specimens of commercial salicylic acid by direct tests, for the quantity of these impurities is usually too small to exercise an appreciable influence on the melting point or the solubility of the acid, but the crystalline form of the acid is a reliable indicator of its purity. As stated above, the pure acid crystallises from dilute spirit in large and distinct crystals, but the presence of even a very small quantity of impurity causes the acid to crystallise in a network of delicate closely interlacing needles.

It is therefore a comparatively simple matter to manufacture a pure salicylic acid—indeed I understand that this is now being done—and in view of the dangers attending the use of an impure acid it seems reasonable that some measures should be taken to ensure the purity of the acid used for pharmaceutical purposes or in the preparation of preservatives of different kinds.

## ERRATUM.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

*The Griffin Roller Mill.* Eng. and Mining J. 49, 589.

THIS mill, designed for the pulverisation of wet or dry ores, phosphates, cements, carbon, and hard and refractory substances, receives its motive power from the vertical shaft which runs in two self-adjusting journal bearings bolted to the timbers in the mill building, or, independently of this, to a specially devised timber or iron frame. The step bearing which carries the weight of all the running parts is fastened to the lower journal box and may be raised or lowered as the accurate adjustment of the working parts of the apparatus requires. A smoothly running universal joint connects the perpendicular shaft at its lower end with the roller shaft; to the latter is secured the cylindrical crushing roll, which on the revolution of the shaft moves freely about in a ring or die (weighing 260 lb. and encased in a base or pan), and by centrifugal force presses against the inner surface of the ring.

\* Any of these specifications may be obtained by post, by remitting the cost price, *plus* postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d. ....	½d.
Above 8d., and not exceeding 1s. 6d. ....	1d.
" 1s. 6d., " " 2s. 4d. ....	1½d.
" 2s. 4d., " " 3s. 4d. ....	2d.

When the material to be pulverised, after crushing in a rock breaker to 1 in. cubes, is introduced into the pan through an automatic feeder, it is stirred up by the 12 lb. shoes or plows attached to the lower side of the roll, and then is thrown against the ring and crushed by the roll. When sufficiently fine the pulverised material passes through screens at the base. It is then carried off, in a special conveyor, through openings in the bottom of the pan outside of the screens. The screening arrangement operates so efficiently as to give passage to four tons an hour of phosphate rock, 90 per cent. of which would pass through a 60-mesh screen. A fan, attached to the shaft above the roll and cased in with it, forces air through the screens into the discharge and keeps the dust within the mill.

For wet grinding, a trough is substituted for the openings in the bottom, and the fan is omitted; otherwise the construction is the same.

The mill is said to grind from 1½ to 4 tons per hour, at 150 to 175 revolutions per minute, according to the character of the material, consuming about 20 horse-power, though an engine rated at 25 horse-power is preferable to one of nominal 20 horse-power. The even distribution of the material to be acted on, its quick discharge when finished, and the uniformity of the work as to fineness, are indicated by the fact that 37 tons 400 lb. of Charleston phosphate rock were pulverised in nine hours, and, when sampled and tested with standard screens, showed 91·5 per cent. able to pass through a 60-mesh and 84 per cent. through an 80-mesh.

The mill occupies 4½ sq. ft., weighs 6,000 lb., and requires but little attendance. The repair is so slight that, in a certain case 1,500 tons of Charleston rock were ground without causing a measurable wear. The wearing parts, *i.e.*, the ring, the tire of the roll (weighing 100 lb.), and the shoes, are easily removed and replaced. The heaviest piece is the pan (2,400 lb.), which could be sectionalised. Outside of this no part weighs over 300 lb. The journal bearings are several feet away from the mill, run cool, and consume about half a pint of oil for 10 hours. The vibration of the apparatus, when based on a good foundation, is light. (Compare this Journal, 1889, 196.)

### PATENTS.

*Improvements in Apparatus for Separating Liquids from Solid Matters Suspended therein.* H. J. Hadden, London. From Gaillet and Huët, Lille, France. Eng. Pat. 972, February 22, 1883. (Second Edition.) 8d.

THIS invention has for its object the separation of solid particles from the liquids in which they are suspended, and is particularly applicable for the clarification of water used for feeding boilers, or other purposes.

The apparatus consists chiefly of a vertical vessel containing a number of parallel partitions, inclined at an angle of about 40° and alternately riveted to the opposite sides of the vessel. These partitions are also inclined sideways at an angle of 45°, and form a series of compartments. The mixture of solid and liquid matter is caused to flow alternately upwards and downwards between the inclined plates, and sufficient space is allowed for the solid particles which glide over the inclined partitions to settle at the bottom of the channels formed by the plates, and from which they can be easily removed. In removing impurities from water by means of chemical precipitation, the chemicals to be dissolved are placed in a vessel near the separating apparatus, both vessels being supplied with water from the same tank through two outlets and two adjustable valves. The proportion between the liquid to be purified and the dissolving liquid can thus be regulated and kept constant.—E. S.

*Improved Method of and Means for Separating Solids from Liquids.* W. Hucks, London. Eng. Pat. 6391, April 15, 1889. 6d.

IN this patent, which consists of improvements on Eng. Pat. 2528 of 1889 (this Journal, 1889, 694), centrifugal force is used to separate the solid matter from the liquid.

A hollow circular chamber is formed in two parts, which can be connected together at their circumference by a water-tight joint, but can be opened or closed at will whilst in motion by a lever attached to the upper half. Inside is a hollow disc, having inlets and outlets, and is rotated by a shaft independently of the chamber, and is provided with perforated plates or wire gauze to intercept the solid matter. Other perforations or diaphragms are also used elsewhere. The liquid enters through a hollow spindle, rotating in a gland, at the bottom of the chamber, and escapes through an outlet. The centrifugal action caused by the rotation of the disc causes the solid matter to be driven towards the circumference, from which it can be removed by raising the top half of the chamber. There are nine claims.—E. S.

*Improvements in the Construction of Apparatus used for Expelling Liquid from, and Compressing Semi-fluid or Plastic Substances.* J. Price, London. Eng. Pat. 6861, April 24, 1889. 8d.

THE improvements relate to the construction of moulds employed in or in combination with presses for expelling liquids, or expressing moisture from solid or insoluble substances, when held in a fluid or plastic condition, where it is required to separate the liquid from the solid portion. The invention is intended to remove the difficulty experienced in removing the pressed material from the mould without affecting its shape or sharpness of outline. The head and bed-plate of the press are provided with loose plates, which form the top and bottom of the mould, and which may have any design on or attached to them. The sides of the mould are capable of a certain amount of vertical motion. The material having been compressed, the plunger is secured, and the sides of the mould are then slid upwards or downwards clear of the compressed material and the loose plates. These plates are then securely locked in position, and, the plunger being withdrawn, the plates and pressed material can be removed in one piece and placed aside until dry, when the plates may be removed.

Preferably, the mould is combined with an arrangement of perforated plates and filtering media described in Eng. Pat. 8491, 1888 (this Journal, 1889, 563).—E. S.

*Improvements in Vacuum Distilling and Evaporating Apparatus.* J. Foster, Sunderland. Eng. Pat. 7343, May 2, 1889. 1s. 1d.

THIS invention embraces the construction and arrangement of parts of apparatus for the distillation and evaporation in vacuo of sugar or other liquids, the process being carried out in two, three, or more vessels, on the principle of the "triple-effect" apparatus. The object is to secure greater convenience in the arrangement of the various parts, and to obtain increased heating surface with a higher degree of efficiency of evaporation or distillation than has hitherto been achieved. The evaporation vessels are of the tubular kind, disposed either vertically or horizontally, the tubes being fitted in cylindrical vessels with suitably constructed end chambers. The liquid is, by preference, passed through the tubes, the separation of the vapour taking place in the end chamber, whence the vapour is led around the tubes of the next vessel, whilst the liquid proceeds to pass through them. The specification fully describes and illustrates the various details. There are nine claims, the first referring to the various modes of combination; the third claim for the duplex and return end chambers; the sixth for the distribution of the liquid through the apparatus, and for its retention in any vessel without interfering with the rest; and the seventh claim for the introduction of *venæ contractæ* at the tube entrances, for the regulation of the speed of the passing liquid, seem to be the most important.—B.

*Improvements in the Method of and Means for Treating or Washing Crushed Ores, Coal, and similar Materials.* O. Bilharz, Freiberg, Germany. Eng. Pat. 7500, May 4, 1889. 1s. 1d.

See under X., page 626.

*An Improved Separating or Assorting Machine for Granular or Pulverulent Materials or Substances.* P. Janssen, Hamburg. Eng. Pat. 8119, May 15, 1889. 6d.

THE assorting machine consists of a closed sieve frame, in which one or more sieves, having a zigzag formation, are arranged, one below the other. The frame is suspended on four rods, so that it may move freely, motion being imparted to it by disc cranks moved by bevel wheels. The material to be sorted is brought through funnels. As the finer material passes through the sieves, the coarser parts are successively urged to the outlets by the motion given to the frame and by the particular zigzag formation of the sieves.

The arrangement of zigzag surface of the sieves has the advantage of allowing the direction of motion of the sieves or sieve frame to be varied as necessity requires, the matter being always urged forwards from the inlet to the outlet.

—E. S.

*Improvements in Evaporating or Condensing Milk and other Liquids.* W. P. Branson and H. W. Neild, London. Eng. Pat. 8882, May 28, 1889. 6d.

THE improvement consists in admitting a small quantity of air into the vacuum pan, below the liquid which is being evaporated or condensed, for the purpose of preventing an undue accumulation of the froth. The air pipe, at its outer (and upper) end, is fitted with a tap, by which the passage of air can be controlled. An inlet pipe of about half an inch in diameter is said to be sufficient for a vacuum pan 6 ft. in diameter.—E. S.

*Improvements in Filtering and in Filter Presses.* F. N. Mackay, London. From J. Baxter and J. Muter, Rangoon, Burmah. Eng. Pat. 8928, May 29, 1889. 6d.

THE object is to control the temperature of liquids during filtration in filter presses. The invention consists: "(1.) In causing a heating or refrigerating fluid to circulate on one side of filter-press plates or trays whilst filtration is being conducted on the other side of the said plates or trays." "(2.) "In making the trays with ways or passages there-through, and in connecting such ways or passages to appliances of any usual or suitable construction for causing heating or cooling liquids to circulate." "(3.) "In constructing filter presses in such a manner that the material to be filtered, and the heating or refrigerating fluid, may be contained between alternate plates or trays."—E. S.

*Improvements in Apparatus for Evaporating Liquids.* D. B. Morison, Hartlepool. Eng. Pat. 9041, May 31, 1889. 11d.

THESE improvements refer to the details of connexions used in apparatus in which water or other liquid is evaporated in closed vessels by means of coils of steam pipes, the rising vapour being conducted away for any desired purpose. The principal object is to facilitate the cleaning of the coils. There are three sheets of drawings and four claims.—B.

*Improvements in the Treatment of Sea Water for Marine Boilers.* W. Bramley, Middlesbrough. Eng. Pat. 9246, June 4, 1889. 4d.

As the scale formed in marine boilers supplied with sea water consists of calcium sulphate, the present invention seeks to remove the lime from sea water by precipitating with a mixture of sesquicarbonates of sodium and potassium, and leaving the magnesia in solution.—G. H. B.

*Improvements in Vacuum Drying Apparatus.* J. Brown and G. Johnston, Glasgow. Eng. Pat. 9850, June 15, 1889. 8d.

THE apparatus consists of an upright iron cylinder with flat ends, which are strengthened for resisting a partial vacuum maintained within, for facilitating the drying of the substances under treatment, such as granular, fibrous or powdery materials. The cylinder contains a number of superimposed circular hollow trays, heated by steam, which circulates through pipes from one tray to the other. An upright shaft passing through the centre openings of the annuli puts in rotation a number of arms with stirrers which sweep the upper surfaces of the trays and deliver the materials from one to the other through suitably placed openings. In order to facilitate the feeding in of the material at the top, and the withdrawal of the dried material below, without affecting the vacuum, a special hopper with valve has been designed, of which the accompanying illustrations give an idea. The figures represent a longitudinal and two cross sections.

Fig. 1.

Fig. 2.

Fig. 3.

The valve consists of the conical plug  $L^1$ , bedded across the hopper casting  $L$ , similarly to the plug of an ordinary cock. The plug is, however, not pierced through, but is only provided on one side with a trough-like recess  $L^2$  which receives the material when turned to the top, and drops it when turned down, at the same time preserving a close joint against the vacuum. For the purpose of disengaging, from the sides of the recess, moist materials that would otherwise adhere, the loose plate  $L^3$  is introduced, the weight of which starts the movement. It may be further assisted by a spring or by a hollow tube  $L^4$  of thin flexible material and suitable shape, which being filled with air and hermetically sealed, expands when turned towards the vacuum in the cylinder, and drives the plate before it. There are two sheets of drawings and three claims.—B.

*Method of and Apparatus for Effecting the Thawing of the Refrigerating Pipes of Air Refrigerators.* C. Linde, Wiesbaden, Germany. Eng. Pat. 10,918, July 6, 1889. 6d.

THE proposed method applies to that class of refrigerating apparatus (represented by the accompanying diagram) in

which the air comes in contact with pipes cooled by the volatilisation of a liquid such as ammonia or carbonic acid contained within them. P represents the compressing pump,

C the condenser,  $L^1$ ,  $L^2$ , and  $L^3$ , are air refrigerators, simultaneously acting as vaporisers of the volatile liquid. The compressed vapours pass through pipe D into C, thence

the resulting liquid through V and valve R into the refrigerators through the cocks  $a^1$ ,  $a^2$ , and  $a^3$ , whilst cocks  $c^1$ ,  $c^2$ ,  $c^3$  are closed. After evaporation the position of the cocks is reversed and the vapours drawn back through pipe S to the pump. If now coil  $L^2$ , for instance, should require to be thawed, the cocks  $a^2$  and  $c^2$  are closed, and the auxiliary cocks and passages  $b^2$  and  $d^2$  opened, connecting the system  $L^2$  with the compression pipes from the pump and with the liquid pipe F. Through the latter the liquid condensed within  $L^2$  during the thawing process, will return. Upon resetting the cocks as at starting, refrigeration again commences. There are two claims.—B.

or (2), and preferably, as—

These formulæ note the fact that the hydrogen has been taken up (in all probability) as water.

The authors prefer the second series of formulæ as extending Brodie's suggestion that the graphites are distinct radicles.

The paper is followed by a thermo-chemical investigation of the compounds described (Compt. Rend. 110, 106—109).—P. J. H.

*Manufacture of Ammonium Chloride from By-Products in Gas Manufacture and Metallic Chlorides.* Dubosc and Heuzey. Bull. Soc. Ind. Rouen, 1889, 438—442.

See under VII., page 614.

## II.—FUEL, GAS, AND LIGHT.

*On the Different Forms of Graphite and their Corresponding Chemical Derivatives.* Berthelot and Petit. Compt. Rend. 110, 101—106.

BERTHELOT has previously put forward the view that the allotropic forms of carbon are really different polymers of the element (Ann. Chim. Phys. [4], 9, 475, and [4], 19, 396). They give rise by the processes of oxidation and hydrogenation to compounds of corresponding complexity. Thus the oxidation of the graphites in the wet way at a low temperature yields certain ternary compounds, the first of which was discovered by Brodie (graphitic acid). Berthelot has since shown that there are several graphites of distinct chemical nature, each one giving rise to (1) a "graphitic oxide;" (2) a "hydrographitic oxide;" (3) a "pyrographitic oxide;" and from these the original form of graphite can again be obtained (Ann. Chim. Phys. [4], 19, 405).

The authors employ the methods described in the memoir referred to, to prepare the graphitic and pyrographitic "oxides" of various species of graphite.

1. *Graphite from Cast Iron.*—The "oxide" corresponds to an empirical formula  $C_7H_2O_3$ , or its multiple  $C_{28}H_8O_{12}$ , which is used not as a rational formula, but for the sake of comparison with other compounds. The oxide is neutralised by 54 per cent. of BaO, hence its least formula is  $C_7H_2O_3$ . It deaggregates suddenly when heated to a certain temperature.

Heated in a sealed tube, the following reaction takes place— $2 C_{28}H_8O_{12} = 4 CO_2 + 6 CO + 5 H_2O + C_{48}H_6O_5$ .

The formula of the pyrographitic oxide,  $C_{48}H_6O_5$ , thus obtained was determined by analysis and by neutralising with baryta (being saturated by 10 per cent. of BaO).

2. *Amorphous Graphite or Plumbago.*—The oxide corresponds either to a formula  $C_{36}H_{20}O_{30} + H_2O$ , or to  $C_{22}H_8O_{12}$ . On heating in a sealed tube the corresponding pyrographitic oxide was obtained as before—

3. *Electric Graphite.*—This substance, formed by the transformation of the carbons in the electric arc, could only be obtained in small quantity, and was not free from ordinary carbon. It yielded a "graphitic oxide" corresponding to a formula  $C_{28}H_{10}O_{19}$ , or else  $C_{16}H_6O_{11}$ . The authors had too little substance to investigate its decomposition by heat.

They point out the great difference of composition in the three graphitic oxides (C = 62.7 per cent., C = 56.2 per cent., C = 51.95 per cent. for cast-iron graphite, plumbago, and electric graphite respectively), and suggest that they may be regarded, either (1) as—

## PATENTS.

*A Method of and Apparatus for altering the Proportions of Mixed Gases.* S. Fox and E. Blass, Leeds. Eng. Pat. 6129, April 10, 1889. 6d.

THE invention relates to a method of altering the proportions of the gases in a gaseous mixture by eliminating or removing from such a mixture definite quantities of the respective gases by compressing the mixture in presence of a suitable absorbent, such as water; the compressed gaseous mixture or absorbent is utilised, under pressure, to aid in driving the compressing pump, the rest of the power required for driving the pump being provided by any suitable motor.—F. S. K.

*An Improved Process of and Apparatus for Manufacturing Heating and Illuminating Gas.* B. Loomis, Hartford, Connecticut, U.S.A. Eng. Pat. 9279, June 4, 1889. 11d.

By this process a high-grade heating gas can be cheaply produced, and this gas may be carburetted or enriched with hydrocarbon oil or vapour, which is "fixed" by finally passing through heated retorts or brickwork flues.

The producer is, as usual, of firebrick (iron cased), but a special feature is that in making the producer-gas the air supply is drawn in at the top, the gas being drawn away at the bottom by means of an exhaustor. Many advantages are claimed for his. Dust and ashes are blown down, and the formation of clinker prevented, while the oily and tarry vapours from the top layers of fresh coal are drawn down into the heated coal below, and converted into valuable carburetted hydrogen gas. Fresh fuel can be more rapidly and uniformly charged, as the charger can work on the top and inspect the interior of the furnace. Waste heat from the gas is used to superheat the steam for the water-gas, while the producer-gas is led through, and, if desired, burned with air in the retort chamber, and then, after passing through a cooler, is drawn through the exhaustor. The water-gas is taken off some little way down from the top, which prevents the melting and caking of the upper fresh layers of coal. This water-gas is mixed with the oil or vapour by means of a spray and a rotating arrangement, and then led through the heated retorts or flues to be fixed, which heating, in this case, being gradual, ensures the gradual expansion and gasification of the oil vapour. This will be clearly explained by the illustration.

A is the producer and c the cone-shaped top (shown also in detail), F' is the main for producer-gas, n being brick-work to absorb heat for subsequent superheating of the steam. A' is the retort chamber, where the gas may be burnt with air, H the cooler, T the exhaustor, Y a ball valve leading to the chimney, which is closed if producer-gas is wanted at X for boilers or otherwise, E is the outlet for the water-gas, R the oil reservoir, and L the rotary mixer.

B B the retorts where the gas is finally heated, and L''' the outlet for the finished illuminating gas. There are four sheets of drawings and 19 claims are made.—D. A. S.

*Improved Apparatus for Generating and Consuming Combustible Gas.* G. Love, Quebec. Eng. Pat. 9454, June 7, 1889. 6d.

Two sets of hollow perforated bars or pipes are arranged in a suitable furnace in such a way that air can be forced through the one series till the fuel becomes incandescent, and then steam or vapour can be forced through the other series for the production of water-gas. An air-chamber is provided at the outlet of this generating furnace to supply air for the complete combustion of the gas so formed. The application of this furnace to a single-flued boiler is illustrated in the specification.—D. A. S.

*An Improvement in Regenerative Gas Furnaces.* R. S. Casson, Brierley Hill. Eng. Pat. 10,050, June 19, 1889. 6d.

See under X., page 627.

*Improvements in the Treatment of Water-Gas.* W. Crookes and F. J. Ricardo Seaver, London. Eng. Pat. 10,164, June 21, 1889. 4d.

THE authors propose rendering water-gas non-poisonous by removing carbonic oxide which as is well known it contains, in about equal proportions with hydrogen. The water-gas is passed over soda lime (preferably through several feet in a retort) at a good red heat; sodium carbonate is formed and hydrogen liberated—

which hydrogen takes the place of the carbonic oxide, and on account of its greater diffusiveness could probably be carburetted or enriched easier than water-gas if desired for illuminating purposes. One thousand cubic feet of mixed gas would require about 320 lb. of soda lime. The sodium

carbonate could be recovered by lixiviation and causticised, and the lime could be reburnt, thus enabling the same materials to be used over again.—D. A. S.

*Improvements relating to the Burning of Liquid Fuel in Boiler Furnaces and the like.* H. J. Haddan, London. From F. F. Amoroso, Venice, Italy. Eng. Pat. 10,392, June 26, 1889. 6d.

A CYLINDER fitted with radiating holders tipped with wick or asbestos is caused to rotate. The holders dip in turn into an open tank or tray containing oil which is kept to a constant level by means of an automatic arrangement. These holders, rising continuously into the fire, burn fiercely. It is claimed that this arrangement is noiseless, and secures the best distribution of the flame. Illustrations are given showing its application to several forms of boilers.—D. A. S.

*A New or Improved Producer for making Ordinary Producer-Gas and Water-Gas and Coke.* J. C. Johnson, Wednesbury. Eng. Pat. 10,581, June 29, 1889. 8d.

THIS producer consists of a firebrick chamber preferably wider at the top than at the bottom. At the base it is sealed by terminating in a trough of water down through which the coke can be drawn by means of a rake. There are two openings for the blast below the middle of the chamber, and there are two outlets for gas at the top. These are so arranged that the blast can be worked alternately from either side, so as to induce a cross current through the mass of fuel. If coke or water-gas be required, the coke is worked down by means of a rake into the water and drawn out, while the steam formed in quenching the hot coke passes up through the incandescent fuel, producing water-gas.

—D. A. S.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Acids of Low Carbon Percentage occurring in Petroleum from Baku.* O. Aschan. Ber. 23, 867—875.

ABOUT two years ago the author procured for the purpose of this investigation, from Estlander of Baku, about 200 kilos. of crude naphtha acids which had been separated from the residue obtained in the purification of petroleum with caustic soda by adding water to the semi-fluid mass and heating to 90°—100° for 48 hours. The clear solution was then treated with sulphuric acid, and the acid thus obtained separated by decantation. The crude acid has a light yellow colour and petroleum-like odour, and shows a specific gravity of 0.9891 at 18°. When subjected to distillation at the ordinary pressure water and hydrocarbons begin to come over; at 200° the acid commences to boil with partial decomposition. The greater portion boils above 300°, only one-third distilling over below this temperature.

Hell and Meidinger some time ago isolated from crude Wallachian petroleum an acid having the formula  $C_{11}H_{13}O_2$ . Markownikow and Oglobin obtained two acids, to which they assigned the formula  $C_{10}H_{15}O_2$  and  $C_{11}H_{15}O_2$ , whilst Krämer has recently isolated an acid of the formula  $C_{15}H_{25}O_2$ . The extensive researches made by Markownikow appear to show that the acids belonging to the group represented by the general formula  $C_nH_{2n-2}O_2$  are the carboxylic acids of hydrocarbons of the  $C_nH_{2n}$  series, called naphthenes, which constitute the principal part of Caucasian petroleum. The same author has recently shown that the naphthenes are hexahydrides of benzene hydrocarbons, so that the corresponding acids must be regarded as hexahydroxybenzoic acid and its homologues. Of these acids those represented by simple formulae are of the greatest interest, as the higher homologues, which contain several isomers, cannot be isolated without considerable difficulty. The author has therefore separated and examined the lowest boiling acids. For this purpose the crude naphtha acid was subjected to distillation and the distillate up to 270° collected. This was then treated with a 5 per cent solution of caustic soda, and after standing for two days the petroleum layer was drawn off and the aqueous solution decomposed with sulphuric acid. A colourless oil was obtained which assumed a dark colour when exposed to light. 100 kilos. of crude acid gave 6 kilos. of low boiling products. In order to isolate the various acids the mixture was methylated and subjected to a long series of fractional distillations. In this manner the methyl ether of hexanaphthenecarboxylic acid was obtained. It boils between 165.5° and 167.5°; forms a colourless oil of 0.90547 sp. gr., having an agreeably fruity odour, which, however, eventually excites nausea. The free acid was prepared by dissolving the ether in alcohol, boiling the solution with a slight excess of potassium hydroxide, and decomposing the potassium salt thus formed with an acid. A yellow oil was obtained which after refining boiled at 215°—217°, and gave by analysis numbers agreeing with the formula  $C_7H_{12}O_2$ . Hexanaphthenecarboxylic acid is a colourless oil possessing a strong odour of valerian. It has a specific gravity of 0.95025 at 18.4°. Bromine has no action at the ordinary temperature, but on heating substitution takes place. Potassium permanganate in alkaline solution is gradually decolourised. Nitric acid causes slow oxidation. Hexanaphthenecarboxylic acid has strongly acid properties. It is isomeric with the synthetical methyl-pentanethylenecarboxylic acid (2:1) recently prepared by Perkin, jun., and Colman. The following salts have been prepared:—The potassium salt is readily soluble in water and alcohol, and is highly hygroscopic. The sodium salt is obtained from alcohol in the form of indistinct flat prisms, which effloresce on heating. The calcium salt is readily soluble in alcohol and water, and crystallises in two forms containing different amounts of water. The barium salt is readily soluble in alcohol, sparingly soluble in water, and forms two modifications. The amorphous salt contains water, and the crystalline salt is anhydrous. The silver salt is sparingly soluble in cold, more readily soluble in hot

water. The cadmium salt forms nacreous laminae sparingly soluble in cold, readily soluble in hot water. The ammonium salt cannot be obtained. On drying, ammonia is liberated and the acid reproduced. The author has also prepared the chloride, amide, and anilide. The chloride boils at 167°—169°. The amide melts at 123.5°, and is readily soluble in alcohol and water. The anilide crystallises in long needles which melt at 93°—94°. Of the homologues of hexanaphthenecarboxylic acid two acids represented by the formulae  $C_8H_{14}O_2$  and  $C_9H_{16}O_2$  have been prepared in a pure form; they boil at 237°—239° and 251°—253° respectively, and their properties will be described by the author in a future communication.—D. B.

*The Occurrence and Extraction of Ozokerite in Galicia.* J. Shotsky. Allg. österr. Chemiker-und Techniker Zeit. 1889, 614 and 651.

THE most important deposit of ozokerite is near Borislav, where it occurs in a marl containing salt. The wax is found in irregular lumps, sometimes of great size, or in layers which frequently die out completely. The neighbouring rock consists of clay-slate, marl and sandstone.

The centre of the basin is richest in wax; in some cases masses of such extent have been tapped that the miners have hardly had time to escape before the workings were filled with the plastic mineral. Such a deposit was recently found in the deepest shaft at Borislav, at a depth of 208 metres (227 yards). In general, however, the yield of wax varies at from 2 to 8 per cent. of the mineral extracted. Ozokerite was first found in this district in 1854 by Doms, who was in search of petroleum with which much of the ground is saturated. At first it was regarded as an unwelcome companion to the petroleum, as it frequently caused the timbering of the shafts to collapse. It was not until about 20 years later that this substance began to attain commercial importance, a method having then been discovered of producing from it a substance resembling bees wax and named cersin.

In 1865 ozokerite, which had previously been regarded as a Crown mineral, was declared free, and the consequence was that a number of shafts were sunk in the district, and much speculation ensued. The land being parcelled out in small plots, the shafts were sunk in the immediate neighbourhood of each other, and much waste and danger ensued. In 1886 the present law was passed, according to which the right of mining for ozokerite may be separated from the ownership of the land. The extraction is now carried out under official supervision.

In nearly every case the mineral is raised through vertical shafts or pits over which a wooden roof is erected. The section of the shafts in the first instance is 3 to 4 square metres (32 sq. ft. to 43 sq. ft.); but when the ozokerite formation is reached, an inner shaft 1 metre square (10.76 sq. ft.) is formed of timber, and the space between this and the timbering of the larger shaft is filled with a rich clay. This construction is adopted to exclude the surface-water, which is kept down by hand-pumps during sinking. From the bottom of the shafts levels are driven into the ozokerite ground, the richer portions being raised and the refuse used to fill up the old workings. The softer parts of the marl are dislodged by means of pick or wedge; but where the rock is hard, and the permission of the mining authorities can be obtained, dynamite is used. The mineral is raised by hand in skips or tubs holding 40 to 50 kilos. (88 to 110 lb.). Hand-ventilators are used for the purpose of ventilation, but explosions of gas are not uncommon, especially after Sundays and holidays. Fatal accidents are, however, rare. Safety-lamps are used in all the mines. The timbering of the shafts requires constant renewal and repairs; in some cases it is almost impossible to keep the shafts perpendicular.

The water is usually raised in tubs, and much difficulty is experienced in getting rid of it after it reaches the surface, on account of the numerous shafts and the broken nature of the ground. The mineral, when it leaves the tubs, is sorted by hand. The waste rock is picked out and tipped to spoil, lumps of ozokerite are specially selected, and the

remainder of the rock, containing fragments of wax, is tipped into tanks full of water. On being well stirred most of the wax rises to the surface and is skimmed off. The residue still contains from 2 to 3 per cent. of wax. The quantity of waste mineral being considerable, and the distance between the shafts small, a special railway has been built to remove the residues from the immediate neighbourhood of the mines.

Only one attempt has been made to mine on a large scale for ozokerite. In this case a circular shaft, 2 metres (6 ft. 7 in.) in diameter and lined with iron tubing, was sunk outside the ozokerite zone, and the deposit was reached by galleries. Trucks holding 500 kilos. (1,102 lb.) were used, and both ventilation and pumping were done by steam-power. The operations on a large scale do not, however, seem to have been successful, the French company which carried them out having now ceased working.

The production of ozokerite in the Borislav district amounted in 1887 to 96 per cent. of the total output in Galicia, and was valued at 152,900*l.*

*On Homologues of Anthracene and Anthraquinone.* K. Elbs. J. prakt. Chem. **41**, 121—151. Conclusion. (See this Journal, 1890, 276—278.)

#### 1 : 2 : 4 Trimethylantracene—

In white fluorescent plates, melting at 244°, described by Gresly (J. Chem. Soc. 1886, 1028) by distillation of pseudocumene-phthalic acid with zinc dust. When oxidised by chromic acid in glacial acetic acid it yields 1 : 2 : 4 trimethylantraquinone, melting at 162°. An unstable *picric acid derivative* was obtained in red-brown needles melting at 145°.

#### 1 : 2 : 4 Trimethylantraquinone—

In long yellow needles, melting at 162°—163°, and subliming without residue; soluble with difficulty in alcohol, more readily in ether, benzene, and xylene. A careful detailed description is given of its preparation from pseudocumene-phthalic acid. Warmed with zinc dust and alkali it becomes a blood-red liquid; with sodium amalgam and absolute alcohol a garnet red solution.

By reduction of 1 : 2 : 4 trimethylantraquinone with zinc dust and ammonia the author obtained a hydrocarbon in colourless plates, melting at 64°, becoming yellow and lowered in melting point, on exposure to air. (Compare this Journal, 1890, 277.) This he considers to be—

#### Trimethylantracylene—

A *picric acid derivative* was prepared in dark-red needles melting at 134°, decomposing on exposure to air and light. The bromination of *Trimethylantracylene* gave a *dibromo derivative*,  $\text{C}_{17}\text{H}_{12}\text{Br}_2$ , crystallising from carbon disulphide in somewhat large yellow transparent prisms, with difficulty soluble in alcohol, and melting at 105°.

#### 1 : 2 : 4 Anthraquinone tricarboxylic acid—

In yellowish white nodules, almost insoluble in water, but easily soluble in alcohol; it neither melts nor decomposes at 320°. By oxidation of 1 : 2 : 4 trimethylantraquinone with dilute nitric acid it formed a red coloured solution with ammonia, but the salt was not obtained pure. Its *monosodium salt* (yellow, with 2 mols.  $\text{H}_2\text{O}$ ); its *disodium salt* (yellowish-red, with 3 mols.  $\text{H}_2\text{O}$ ); its *normal sodium* (blood-red), *calcium* (rose-red), *copper* (green), *lead* (yellow), and *silver* (red) salts are described. The *ethyl salt* occurs in small yellow lustrous plates, melting at 125°.

#### 1 : 2 : 4 Anthracene tricarboxylic acid—

A deep yellow precipitate, insoluble in water but soluble in alcohol, petroleum spirit, and benzene. It has no definite melting point, but at over 260° it sublimes, giving a red sublimate, which is probably the anhydride.

Prepared by reduction of the preceding acid with zinc dust and ammonia. The solutions of the *alkali salts* are greenish-yellow with blue fluorescence. The *silver salt* is greenish-yellow. By nitric acid 1 : 2 : 4 trimethylantraquinone three nitro-compounds are formed, two isomeric mono-compounds and one dinitro-compound.

The author terms the two former I. and II. respectively. 1 : 2 : 4 *Mononitro-trimethylantraquinone I.* is a red powder insoluble in petroleum spirit, alcohol, and ether, but soluble with difficulty in acetic acid, chloroform, carbon disulphide, and acetone, but easily soluble in boiling xylene and benzene, melting with decomposition at 195°—200°, and subliming in small yellow needles.

The 1 : 2 : 4 *nitro-antraquinone tricarboxylic acid* forms in yellow crystals insoluble in water, but soluble in alcohol, ether, &c. It melts with decomposition at 308°—310°. The three *sodium salts* (clear yellow, purple-red, and blood-red) are described, and also the normal *calcium*, *barium*, *strontium*, *nickel*, *cobalt*, *lead*, *copper* and *silver salts*. The *amido acid* was obtained in small deep-red plates, melting at 210°, soluble in boiling water and in alcohol.

*Mononitroanthraquinone II.* crystallises badly and could not be obtained pure. It is a pale red precipitate decomposing at 180°, insoluble in alcohol and ether but soluble in glacial acetic acid, benzene and xylene. The corresponding *tricarboxylic acid* formed yellowish-red crystals soluble with difficulty in water, easily in alcohol, ether, and benzene, and melting with decomposition between 360° and 370°. Its three *sodium salts* (all red) its neutral *calcium*, *barium*, *strontium*, *nickel*, *lead*, and *copper* (red needles), and *silver salts* are described. The *copper salt* dissolves in ammonia with a red colour, while the *copper salt* of the I. acid is green and dissolves in ammonia to an emerald-green colour. The *amidotricarboxylic acid* occurs in deep red plates melting at 255°, soluble in water and alcohol and in caustic potash to a red, and in hydrochloric acid to a yellow colour. The *amidoquinone* in deep red crystals melted at 154°—155°, and sublimed in lustrous dark red needles melting at 156°, soluble in alcohol and benzene.

1 : 2 : 4 *Dinitro-trimethylantraquinone* in deep yellow crystals, melting at 340°—360° with decomposition, distinctly soluble in water and easily in alcohol, &c. The *Tricarboxylic acid* was prepared and its *silver salt* (purple-red).

#### 2 : 1' : 4' Trimethylantracene—

$\text{C}_6\text{H}_5 : (\text{CH}_3)_2 : \text{C}_2\text{H}_2 : \text{C}_6\text{H}_3\text{CH}_3 [\text{CH}_3 : \text{CH}_3 : \text{CH}_3 = 2 : 1' : 4']$   
In colourless plates with green fluorescence subliming below 100°, and melting with decomposition at 227°, soluble in boiling alcohol ether, &c. (compare J. Chem. Soc. 1887, 941).

#### 2 : 1' : 4' Trimethylantraquinone—

$\text{C}_6\text{H}_5 : (\text{CH}_3)_2 : \text{C}_2\text{O}_2 : \text{C}_6\text{H}_3\text{CH}_3 [\text{CH}_3 : \text{CH}_3 : \text{CH}_3 = 2 : 1' : 4']$   
In yellow needles melting at 184° and subliming; sparingly soluble in alcohol but easily in glacial acetic acid. On oxidation a mixture of the *di-* and *tricarboxylic acids* resulted. The *silver salt* of the former is described.

#### 3 : 1' : 3' Trimethylantracene—

$\text{C}_6\text{H}_5 : (\text{CH}_3)_2 : (\text{C}_2\text{H}_5) : \text{C}_6\text{H}_3\text{CH}_3 [\text{CH}_3 : \text{CH}_3 : \text{CH}_3 = 3 : 1' : 3']$   
Melting at 222°, slightly soluble in alcohol, but easily in carbon disulphide; made by condensation of *di-m-xylol-ketone*. (Cosaek, Diss. Freiburg, B. 1889.)

On bromination *γ-dibromo 3 : 1' : 3' trimethylantracene* is produced in yellow plates melting at 142°.

#### 3 : 1' : 3' Trimethylantraquinone—

$\text{C}_6\text{H}_5 : (\text{CH}_3)_2 : \text{C}_2\text{O}_2 : \text{C}_6\text{H}_3\text{CH}_3 [\text{CH}_3 : \text{CH}_3 : \text{CH}_3 = 3 : 1' : 3']$   
In yellow needles melting and subliming at 190°, with difficulty soluble in alcohol, easily in glacial acetic acid. By oxidation of the preceding compound with chromic acid, its *Tricarboxylic acid* was prepared in yellow plates melting at over 300°, almost insoluble in water and only sparingly in the

usual solvents. The *ammonium salt* (flesh coloured) and *barium salt* (cherry red) are described. Naphthanthracene,  $C_{18}H_{14} : (C_2H_2) : C_{10}H_6$ , by reduction of naphthanthraquinone, which in turn is the product by abstraction of water from naphthoyl-*o*-benzoic acid (see Ber. 19, 2209).

The author failed to obtain phenylanthraquinone by condensation of *phenylbenzoyl-o-benzoic acid*.

The last mentioned acid  $CO_2H.C_6H_4.CO.C_6H_4.C_6H_5$  was obtained in small yellowish-white needles melting at  $225^\circ$ , soluble with difficulty in petroleum spirit, but easily in alcohol, ether, &c. The *sulphonic acid* derivative and its *barium salt* were obtained. It was prepared by warming a mixture of diphenyl-phthalic-anhydride and aluminium chloride in petroleum spirit boiling at  $90^\circ$ – $100^\circ$ , which also is the best temperature for the reaction. After distillation with steam, the residual acid was dissolved in dilute soda solution from which it was precipitated by hydrochloric acid. The *nickel salt* (pale green), the *copper salt* (pale blue), the *lead salt* (brownish yellow), and the *silver salt* (white) were prepared from the *ammonium salt*, and are described.

A *lactone*, the inner anhydride of phenylbenzylhydriyl-ortho-benzoic acid—

is the chief product obtained by reduction of the phenylbenzoylorthobenzoic acid in alcoholic solution with zinc dust and ammonia. It forms colourless crystals melting at  $204^\circ$ , subliming in part when heated higher, the sublimate melting at  $205^\circ$ – $206^\circ$ . The *lactone* is soluble in the usual solvents. Further reduction produces *phenylbenzylorthobenzoic acid*,  $C_6H_5.C_6H_4.CH_2.C_6H_4.CO_2H$ , in colourless or slightly red crystals melting at  $184^\circ$ – $185^\circ$  without decomposition, soluble in alcohol and ether, but almost insoluble in water. Its *silver salt* (white) is described. The author concludes with a summary of the results of the foregoing communication.—D. A. S.

#### PATENT.

*Process for Cleansing and Bleaching Fibrous Substances and for Fixing Organic Colouring Matters thereon by Means of Acid and Alkaline Residues of Naphtha Manufacture, or of specially prepared Substances analogous thereto.* V. Schevelin, Bulakna, and P. Mindovsky, Moscow, Russia. Eng. Pat. 8107, May 15, 1889. *8d.*

See under VI., page 612.

## IV.—COLOURING MATTERS AND DYES.

*Normal Cumene Sulphonic Acids.* A. Claus and O. Welzel. J. prakt. Chem. 41, 152–158.

PATERNÒ and Spica (J. Chem. Soc. 1877, 707) described the ortho and para ( $\alpha$  and  $\beta$ ) cumene sulphonic acids. The authors have since prepared these.

There is a marked difference in the solubility of these salts in water, the  $\alpha$ -sulphonates being soluble with difficulty and crystallise readily, while the  $\beta$ -sulphonates are very soluble in water and do not crystallise well. The authors, as the result of their research, find considerable difference between their acids and those of Paternò and Spica, and doubt if the latter obtained the true acids.

The acids were best prepared from their *nickel salts*; the  $\alpha$ -salt crystallised in light green lustrous needles on cooling the hot solution, while the  $\beta$ -salt did not crystallise even from a concentrated solution, but was obtained on evaporation as a yellowish-green powder.

#### *n-cumene-orthosulphonic Acid*—

In colourless needles or small columns with one mol. of water. Soluble in alcohol and water. The *nickel salt*, the *chloride* and *amide* are described. *Orthobromocumene* was obtained as a yellow oil boiling at  $222^\circ$  (uncorr.); on oxidation with nitric acid this yielded orthobromobenzoic acid. The authors are still working on the bromosulphonic acids.

#### *n-Cumeneparasulphonic Acid*—

In needle-shaped crystals. Both acid and salts are more soluble in water and alcohol than the foregoing. The *amide* and the *p-bromo derivative* (boiling at  $220^\circ$  uncorr. and solidifying on cooling) were obtained. The latter was oxidised to *p-bromobenzoic acid*, melting at  $251^\circ$  (uncorr.)

#### *o-bromocumeneparasulphonic Acid*—

was prepared, and gave on treatment with superheated steam bromocumene, which in turn on treatment with dilute nitric acid gave pure *o-bromobenzoic acid* melting at  $147^\circ$  (uncorr.).—D. A. S.

*On Truxene and Truxene Derivatives.* C. Liebermann and O. Bergami. Ber. 23, 317–322.

TRUXONE, which had been obtained by one of the authors (Ber. 22, 785) by treating  $\alpha$ -truxilic acid with concentrated sulphuric acid, yields on reduction the hydrocarbon ( $C_9H_6$ )<sup>2</sup>, which has a very high melting point, viz.,  $360^\circ$  C. Hausmann (Ber. 22, 2023), starting from a different product,  $\alpha$ -hydrindone, has also arrived at a hydrocarbon ( $C_9H_6$ )<sup>2</sup> (by means of dehydration with hydrochloric acid), which seems to be identical with truxene, which, however, had not yet been proved by Hausmann.

According to the formula—

which Hausmann gives to truxene, it ought to yield on oxidation the same tribenzoylenebenzene obtained by Gabriel and Michael (Ber. 21, 1007). This was confirmed. The body obtained showed only a slight difference on analysis, evidently due to traces of the hydrocarbon, from which it could not be freed entirely. The authors therefore feel inclined to assign a tri-molecular formula to truxone—

They have, however, not yet succeeded in producing tribenzoylbenzene by oxidation from above compound, some small quantities only being formed by melting with caustic potash. They could not investigate the subject any farther in this direction, on account of scarcity of material.

Truxone-oxime-anhydride and acetyl-truxone-oxime were also prepared by treatment with hydroxylamine. The potash melt yielded the body,  $C_{28}H_{16}O_3$ , dihydrodiphenylencoxy-anthraquinone, having a great similarity with the colouring matters of the anthraquinone group.—O. J. S.

*Notes on Indazole Derivatives.* H. Strassmann. Ber. **23**, 714—718.

VICTOR MEYER obtained by the action of diazobenzene-chloride on dinitrophenylacetic ether a compound—

which yielded with caustic potash a deep blue potash salt. This body is, however, unstable and undergoes change on standing a few minutes, whilst on boiling it changes immediately into a yellow salt, losing methyl alcohol, potassium nitrite being meanwhile formed. V. Meyer explains these reactions by the following equation—

and calls the new acid Nitrophenylindazole carbonic acid. This body, though a nitro-compound, *cannot be reduced*. Stannous chloride, tin, and hydrochloric acid, glacial acetic acid, and zinc dust are without any action upon it, even on continued ebullition. Ethyl alcohol acts on the methyl ether of this acid (m.p.  $192^\circ$ ) in presence of hydroxylamine hydrochloride after heating for eight hours at  $160^\circ$ — $180^\circ$  C., producing yellow needles melting at  $159^\circ$  C. They are the ethyl ether of the same acid. The same result is produced, if instead of hydroxylamine hydrochloride free hydrochloric acid be used.

The indazole compound dissolves in fuming nitric acid forming a mononitro-compound of the methyl ether  $C_{15}H_{10}N_2O_4(NO_2)$  melting at  $281^\circ$  C., which can be easily reduced to an amido-compound. Fuming sulphuric acid forms with the indazole a sulphonic acid. Some further experiments are described which, however, were not successful in explaining the constitution of these complicated compounds.—A. L.

*On Oreinol- and Resoreinol Colours.* R. Nietzki and H. Maackler. Ber. **23**, 718—726.

WESELSKY and Benedikt have treated the ethyl ethers of resoreinol with nitric acid containing nitrons acid in the same manner as described for the preparation of resazurinol (this Journal, 1890, 489). They obtained two substances, of which one separates from the ethereal solution, whilst the second is obtained after shaking the ether solution with caustic alkali and evaporating. The author observed on repeating these experiments that the diethyl ether does not yield any of the latter substance, whilst it can be readily prepared from the mono-ethylether. The formula is  $C_{14}H_{11}NO_3$ , and it is resorufinol-mono-ethyl ether,  $C_{12}H_6NO_3C_2H_5$ , melting at  $225^\circ$  C. The first body, described by Weselsky and Benedikt, the authors were unable to prepare. It is probably resazurinol ethyl ether.

Oreirufinol was obtained from oreinol by treating it like resoreinol in ethereal solution with fuming nitric acid. It forms dark brown needles soluble with a red colour in alkalis. It is a dimethylresorufinol  $C_{12}H_3(CH_3)_2NO_3$ . Bromine

changes oreirufinol into a blue colouring matter exhibiting strong fluorescence, very similar to Resorufinol blue. Acetic anhydride forms on heating with oreirufinol a monacetyl derivative, crystallising in orange-yellow needles melting at  $204^\circ$  C.

Liebermann described a colouring matter which he obtained by the action of sulphuric acid containing nitrons acid, on oreinol. This substance was identified by the authors as Oreirufinol. Oreirufinol may be further prepared by heating nitroso-oreinol with oreinol in sulphuric acid solution. Nitroso-oreinol can be readily prepared according to Fèvre's method; it forms yellow needles, exploding at  $157^\circ$  C.

*Action of Quinonedichloro-imide on Resoreinol and Oreinol.*—If Quinonedichloro-imide acts on resoreinol in concentrated sulphuric acid solution no formation of colouring matter takes place. Reaction sets in, however, when an alcoholic solution is taken. The yield of colouring matter is very small, and purification is extremely difficult on account of the abundance of by-products. The authors discovered that the action of quinonedichloro-imide on oreinol is far more successful. One molecule of quinonedichloro-imide dissolved in 20 parts of alcohol is gradually added to a molecular weight of oreinol in alcoholic solution. The mixture changes to a beautiful red with yellowish fluorescence. After heating for several hours on the water-bath, water and an excess of ammonia are added. A base is thus precipitated which is purified by means of its sulphuric acid salt which is with difficulty soluble. The base crystallises in small brown needles and has the formula  $C_{13}H_{10}N_2O_2$ . It is insoluble in water but soluble in alcohol with a red-violet colour. Its constitution is either—

The latter formula (II.) is probably the correct one. The body, which is of decided basic character, and insoluble in caustic soda, forms only a monacetyl derivative and a diazo-compound, which combines with naphtholsulphonic acid, yielding colouring matters. All these properties can only be explained by formula No. II. The authors propose to name this body *Oreirufamine*.

The compound prepared from resoreinol—*Resorufamine*—resembles very much the already described compound. Its preparation is, however, far more difficult.—A. L.

*On Amidochrysene.* R. Abegg. Ber. **23**, 792—793.

MONONITROCHRYSENE, prepared according to Schmidt's method, melting at  $205^\circ$  C., forms no amido-compound when treated with tin and hydrochloric acid or zinc and acetic or hydrochloric acid. On heating it with stannous chloride and hydrochloric acid in a sealed tube, a substance free from nitrogen was obtained.

The amido-compound is however produced by boiling a mixture of pure nitrochrysene, a little red phosphorus and hydriodic acid (sp. gr. 1.7) until the brown colour changes to a light grey. The powder obtained after washing and drying is the hydriodide of amidochrysene. It is purified by solution in alcohol, filtration, and precipitation with alcoholic caustic potash. Recrystallised from nitrobenzene, benzene, or alcohol, amidochrysene forms a yellowish brown powder, melting at  $201^\circ$ — $203^\circ$  C., and exhibiting in its solutions blue fluorescence.—A. L.

*On some New Diphenyl Derivatives.* E. Täuber. Ber. **23**, 794—798.

*m*-DINITROBENZIDINE is obtained by dissolving 28.2 grms. ( $\frac{1}{10}$ th mol.) of pure benzidine sulphate in 300 grms. of sulphuric acid at a temperature not exceeding  $50^\circ$ — $60^\circ$  C.

After cooling from  $10^{\circ}$ – $20^{\circ}$  C., 20.2 grms. of potassium nitrate are gradually added and the mixture is allowed to stand for several hours. It is then poured into three times its volume of water, filtered from some impurities and precipitated with sodium carbonate or ammonia. The precipitate is dissolved in hydrochloric acid, boiled with animal charcoal and reprecipitated with ammonia. The base is recrystallised from alcohol and forms yellow plates, melting at  $214^{\circ}$  C. It forms a diazo-compound which can be combined with amines and phenols; but the resulting colouring matters have no affinity for cotton fibre. The bodies obtained from naphthylamine sulphonic acids are bluer than the corresponding benzidine derivatives, whilst the combinations with naphthol sulphonic acid are redder than the benzidine colouring matters.

*m*-Mononitrobenzidine is obtained in the same way as above described, the only alteration being to use half the quantity of potassium nitrate. It forms long red needles like chromic acid, melting at  $143^{\circ}$  C. The colouring matters are in shade and in affinity to cotton, between the benzidine and dinitrobenzidine colours.

*m*-Diamidobenzidine was prepared by reducing the dinitro compound with tin and hydrochloric acid. After the usual purification the base was obtained in plates, melting at  $165^{\circ}$  C. It does not act on orthodiketones and forms brown colouring matters with nitrous acid. Its salts are with difficulty soluble in water.

*m*-Monamidobenzidine forms long colourless needles, melting at  $134^{\circ}$  C., is capable of producing colouring matters of the Chrysoidine and Vesuvine colours. Its constitution is—

The diamidobenzidine can either be—

(I.)

(II.)

A body of the former constitution ought to yield by treating with hydrochloric acid under pressure a diamido-carbazol—

As the author did not succeed in obtaining this body, he concludes No. II. to be the correct formula.—A. L.

*On α-Hydroxynaphthoic-monosulphonic Acid.* K. König. Ber. 23, 806–810.

$\alpha$ -HYDROXYNAPHTHOIC-MONOSULPHONIC acid loses very easily its carboxyl and sulphonic groups. On boiling the acid with dilute sulphuric acid abundant quantities of  $\alpha$ -naphthol are formed. On heating the acid with water in a sealed tube only  $\alpha$ -naphthol was obtained. If, however, the well-dried acid sodium salt be heated to  $180^{\circ}$  C. the sodium salt of naphtholsulphonic acid is formed.

*Action of Nitric Acid on α-Hydroxysulphonaphthoic Acid.*—On gently heating this acid with an excess of dilute nitric acid dinitronaphthol, melting at  $138^{\circ}$  C., commonly called “Martius Yellow,” is formed. If, however,

hydroxysulphonaphthoic acid be suspended in five times its weight of glacial acetic acid, and 1 mol. of nitric acid sp. gr. 1.48, dissolved in four times its volume of glacial acetic acid, be gradually added, nitrohydroxynaphthoic acid is the only product of the reaction. It is identical with the acid described by Burkard as *p*-nitronaphthol-carboxylic acid. On heating with water to  $150^{\circ}$  C., mononitronaphthol, melting at  $164^{\circ}$  C., from this compound by reduction amidonaphthol, yielding on oxidation  $\alpha$ -naphthoquinone, were prepared. The author concludes that the sulpho group is in the para-position to the hydroxy group.

*Action of Diazobenzenechloride on Sulpho-α-hydroxynaphthoic Acid.*—Diazobenzene chloride combines readily with the sulphonic acid. The colouring matter is, however, nothing but the sodium salt of the benzene-azo- $\alpha$ -naphtholsulphonic acid, the carboxyl group being eliminated in the reaction. By reduction with stannous chloride and hydrochloric acid an amidonaphtholsulphonic acid—

was prepared. It is with great difficulty soluble in water and alcohol; its alkaline solutions soon change to a dark green, on acidulation the tint changing to red.

The author further prepared the colouring matter from diazobenzenechloride and Neville and Winther's  $\alpha$ -naphthol- $\alpha$ -sulphonic acid, and proved the complete identity of this dyestuff with the one above described.—A. L.

*On the Action of Chlorine on Pyrocatechol (Catechol) and o-Amidophenol.* Th. Zincke and F. Küster. Ber. 23, 812–831.

THE authors publish in an explicit manner their views on the theoretical aspect of these reactions, and describe finally  $\gamma$ : $\gamma$ -hexachloro-*R*-pentenehydroxy-carboxylic acid and its phosphoric ester.—A. L.

*On Indulines.* O. Fischer and E. Hepp. Ber. 23, 838–841.

THE simplest induline of the naphthalene series, viz., Rosinduline, has the constitution—

There ought to be therefore a product in the benzene series of the formula—

The authors think they have been successful in preparing this colouring matter. The Farbwerke vorm. Meister, Lucius, at Höchst, have obtained a patent for the production of an induline,  $C_{24}H_{18}N_4$ , soluble in water. It is formed in the amidoazobenzene melt, when this is heated only a short time in presence of an abundant quantity of aniline hydrochloride. The new product  $C_{18}H_{13}N_3$  is prepared in an analogous way. A mixture of 160 grms. of amidoazobenzene, 400 grms. of aniline, and 320 grms. of aniline salt are heated until a blue colouration begins to be formed. The reaction commences at  $130^{\circ}$  C. It is continued for 10 minutes at  $160^{\circ}$  C. The mixture is then rendered basic, neutralised with the theoretical quantity of sodium carbonate, and the aniline removed from it by distillation with steam. The residue was boiled with  $1\frac{1}{2}$  litres of acetic acid of 30 per cent. strength; the solution filtered hot and allowed to cool slowly. After several days' standing, a considerable quantity of a crystalline precipitate separated out, which contained

the acetate of the induline  $C_{23}H_{13}N_4$ . The mother-liquor yielded on addition of hydrochloric acid a blue amorphous precipitate, which consists of a mixture of hydrochlorides of  $C_{23}H_{13}N_4$  and  $C_{15}H_{13}N_3$ . The free bases were dissolved in hot benzene and the induline  $C_{23}H_{13}N_4$ , being soluble with far more difficulty in this menstruum, crystallised out first. After repeated recrystallisation the new product was obtained pure, in magnificent needles with a beetle-green lustre, and melting at  $135^\circ C$ . The product was soluble in ether, benzene, and alcohol, with a magenta colour. Its acetic acid solution is reddish violet and it dissolves in sulphuric acid with a blue-violet colour. The hydrochloride, sulphates and nitrates are easily soluble in hot water and dye fibres a reddish violet. Heated with hydrochloric acid to  $150^\circ C$ , it loses ammonia and a new colouring matter is formed, probably  $C_{15}H_{13}N_3O$ , which is redder in its solutions than the original colouring matter. The solutions of the base show a beautiful brownish red fluorescence. If the induline,  $C_{23}H_{13}N_4$ , could be reduced to phenazine the whole induline question would be solved, since all other indulines of the benzene series are derivatives of this, either containing the aniline, phenyl, or paraphenylenediamine residue. The latter acts with particular ease on all indulines, as is well known to manufacturers; and as there are considerable quantities of paraphenylenediamine formed in the process of making indulines, disappearing again if the reaction be continued a long time, there is no doubt that it serves for the formation of the *blue indulines*. In the above described process abundant quantities of paraphenylenediamine could be isolated. The authors further observed that in all processes for preparing indulines the addition of the diamine lowered the temperature of the reaction considerably. Azophenine, anilido-quinoneanilide, anilidonaphtho-quinoneanil, benzene-azo- $\alpha$ -naphthylamine, &c., were acted upon easily, when these bodies were heated in alcoholic solution with paraphenylenediamine and its hydrochloride from  $150^\circ$ — $170^\circ C$ . To decide in which way this base acts on indulines, phenylrosinduline was heated in alcoholic solution with two parts of phenylenediamine and  $\frac{1}{2}$  parts of its hydrochloride to  $160^\circ C$ . A new colouring matter was formed. Its free base was nearly black, crystallising from alcohol in dark needles melting at  $247^\circ C$ . It had the formula  $C_{23}H_{20}N_4$  and the constitution—

If heated with hydrochloric acid to  $180^\circ C$ , it forms paraphenylenediamine and Rosindone—

the latter crystallising in beautiful red plates with a golden lustre, melting at  $259^\circ C$ .

*p*-Phenylenediamine acts on benzene indulines probably in the same way. If it enters them, it changes the shade of the colouring matter from violet to blue.—A. L.

*On the Oxidation of o-Phenylenediamine.* O. Fischer and E. Hepp. Ber. **23**, 841—847.

THE authors discovered some time ago that the oxidation product of orthophenylenediamine formed with ferric chloride, is a diamidophenazine, which has its two amido groups either in one or two different nuclei. They now describe some salts, and the diformyl derivatives of the compound mentioned. The hydrochloride has the formula  $C_{12}H_{10}N_4 \cdot HCl + 3 H_2O$ , the sulphate the formula—

*Constitution of Diamidophenazine.*—Though the formation of the diacetyl- and diformyl-compounds is contrary to the hypothesis that both amido groups are in one ring, there are other characteristics which render it highly probable that these groups are in the ortho position to each other. Nitrous acid does not produce a diazo-compound; benzaldehyde acts on the hydrochloride at  $100^\circ C$ , with evolution of hydrochloric acid (Ladenburg's reaction for orthodiamines), and it forms with benzil a quinoxaline derivative. The latter product is prepared by boiling a mixture of 1 gm. of diamidophenazine, 2 grms. of benzil, and 20 grms. of alcohol for half an hour. Then 5 grms. of glacial acetic acid are added and the boiling is continued for another hour. The product of the reaction separates out after some time, and is purified by crystallisation from toluene. It forms small reddish-brown plates, soluble in concentrated sulphuric acid with a dark blue colour, and has the formula  $C_{20}H_{16}N_4$ .

The constitution of diamidophenazine must therefore be—

*Dihydroxyphenazine hydrochloride* is obtained by heating the diamido-compound with 10 parts of concentrated hydrochloric acid in a sealed tube to  $200^\circ C$ . The free base is prepared from the sulphate by addition of sodium carbonate. It crystallises from dilute alcohol in reddish-yellow needles with  $\frac{1}{2}$  mol. of  $H_2O$ , and has the composition  $C_{12}H_8N_2O_2 + \frac{1}{2} Aq$ .

*Diacetyldihydroxyphenazine* is prepared by heating one part of dihydroxyphenazine with 15 parts of acetic anhydride. Light yellow leaves melting at  $230^\circ C$ , and soluble in benzene.

Hübner and Frerichs studied the action of *iodocyanide* on orthophenylenediamine, and obtained a yellow base which they believed to be—

The authors, however, proved that this body is diamidophenazine.

By the action of amido-azo bodies on orthophenylenediamine, monamidophenazines or eurhodines are formed. By the action of 1 mol. of the diamine on 1 mol. of benzene azo- $\alpha$ -naphthylamine, a base  $C_{16}H_{11}N_3$ , was obtained, soluble in alcohol, and melting at  $264^\circ C$ . Its solution exhibits a yellowish-green fluorescence. With an excess of acetic anhydride, it yields an acetyl compound  $C_{18}H_{13}N_3O$ , and on heating with hydrochloric acid in a sealed tube at  $180^\circ$ — $200^\circ C$ , a hydroxy derivative  $C_{16}H_{10}N_3O$ , ammonia being eliminated. On distillation of this body with zinc dust naphthophenazine, melting at  $142^\circ C$ , is formed. The reaction between orthophenylenediamine and benzene-azo- $\alpha$ -naphthylamine must be expressed by the following equation:—

—A. L.

*On Alicyclic and Aromatic Tetrahydro- $\beta$ -naphthylamine.* E. Bamberger and M. Kitchelt. Ber. **23**, 876—884.

FIFTEEN grms. of naphthylamine are reduced with 20 grms. of sodium. The solution of the mixture of bases in petroleum spirit is treated with carbonic acid, or instead of repeating this operation several times, the carbonates are dissolved in acetic acid of 5—8 per cent. strength; the aromatic bases

remain undissolved as a brown oil, which can be easily separated. If on addition of diazobenzenesulphonic acid no colouration takes place, the separation is complete.

*Alieyclic Tetrahydro-β-naphthylamine acetate—*

melts at 155.5°—156° C.

*Alieyclic Tetrahydro-β-naphthylamine nitrate—*

melts at 210°—212° C.

*Alieyclic Benzylidenetetrahydro-β-naphthylamine—*

obtained from the base and benzaldehyde at the ordinary temperature, forms tablets or prisms melting at 51.5°—52° C. It is soluble in petroleum spirit, ether, benzene, and boiling alcohol, but insoluble in water. Whilst very stable towards alkalis it is easily decomposed by acids into the base and the aldehyde.

By the oxidation of the base with potassium permanganate a mixture of phthalic acid and orthocarboxylic hydrocinna-monic acid was obtained. If, however, the alieyclic β-tetrahydronaphthylamine be oxidised with potassium bichromate and sulphuric acid, α-naphthoquinone, melting at 123.5° C. and α-naphthol, melting at 95° C. were obtained, besides phthalic acid. This is indeed exceedingly surprising, considering that a pure β-derivative was the material which the authors used.

*Aromatic Tetrahydro-β-naphthylamine* is formed to the extent of about 3 to 4 per cent. on the reduction of β-naphthylamine. To the mixture of crystals of the hydrochlorides remaining after distilling off the amylalcohol caustic soda is added until the mixture becomes alkaline. Thus the aromatic bases are set free, and may be distilled off with steam. They are converted into salts and concentrated. After further addition of caustic soda the base is then extracted with ether, the solution exhibiting a blue fluorescence. On evaporation of the ether the residue is dissolved in petroleum spirit, and this solution is then treated with moist carbonic acid. The filtrate from the solid carbonate is distilled and a product is obtained between 275°—277° C., solidifying and melting after several recrystallisations from hot petroleum spirit at 38° C. It forms salts with mineral acids, can be diazotised, and the diazo-compound yields colouring matters in combination with phenols and amines.

On the oxidation of the base with potassium permanganate adipic acid was obtained, melting at 148° C. and solidifying at 144° C. Its constitution is—

and the base must therefore be—

*Aromatic Tetrahydro-β-naphthol—*

was obtained from the diazo compound of the base above described, by boiling it with dilute sulphuric acid. It melts at 58° C., and is identical with that prepared by reducing β-naphthol.—A. L.

*On Aromatic Tetrahydro-β-Naphthol.* E. Bamberger and M. Kitschelt. Ber. 23, 885—887.

The reduction product of 48 grms. of β-naphthol is distilled at a pressure of 55 mm. until the temperature rises to 196° C. The distillate is treated with caustic soda, which dissolves the aromatic compound. Some, however, of the alieyclic body is mixed with it, and to produce separation, steam is passed through the alkaline solution until no more oil insoluble in alkali distils over. The remaining alkaline solution is acidified, steam again passed through the distillate, saturated with sodium chloride and shaken with ether. On distilling the latter β-tetrahydronaphthol was obtained in white needles, melting at 58° C. It is soluble in ether, alcohol, benzene, chloroform, and boiling petroleum spirit, little soluble in cold, more so in hot water. Calcium hypochlorite separates from its aqueous solution white flakes; ferric chloride colours it a bluish-green, and on heating a brownish-yellow precipitate is produced; chloroform and caustic soda colour its solution greenish-yellow. If aromatic β-tetrahydronaphthol be dissolved in concentrated sulphuric acid and sodium nitrite be added, the solution is coloured pink, the tint on heating changing to a beautiful violet. β-naphthol treated in the same way produces in the cold a reddish-brown solution, which on heating turns to a violet-brown, combined with *p*-diazobenzene sulphonic acid a chert-red colouring matter is formed.—A. L.

*On Quinone-imides and Amido-quinones.* F. Kehrman. Ber. 23, 897—907.

QUINONE-IMIDES are bodies of the typical formula—

Quinone-imide.

Quinone-di-imide.

Amido-quinones the author considers to be constituted as follows:—

Amido-quinone.

Anilido-quinone.

These classes of bodies have been closely studied of late, and Fischer and, at the same time, Bandrowsky have discovered that azophenine is dianilidoquinonedianilide—

The author studied the action of aniline on monochloro-*p*-dihydroxyquinone. If the latter be treated with an alcoholic solution of aniline, the liquid is at first coloured dark brown and separates somewhat suddenly large brown crystals of a blue violet lustre. This compound proved to be identical with Niemeyer's Chlorodianilidoquinone—

obtained by the action of alcoholic aniline on metadihydroxyquinone.

If, however, to a boiling solution of chlorodihydroxyquinone in glacial acetic acid so much aniline acetate be

added that the whole of the quinone is converted into the aniline salt separating in red crystals, and the boiling be continued for five minutes, the salt re-dissolves, and on cooling greenish-black needles with a blue lustre are obtained isomeric with chlorodiamidoquinone, melting after recrystallisation from alcohol at 240° C. with some decomposition. The compound is insoluble in water, with difficulty soluble in alcohol and ether, easily in boiling benzene and glacial acetic acid. The solution in concentrated sulphuric acid has a beautiful green colour, changing on dilution with a little water to blue, and precipitating the anilide on mixing with much water. This is soluble in caustic alcoholic potash with a dark red colour. On boiling with dilute caustic potash until the solution is coloured light red, a body is obtained which is either—

Anilidoxyhydroxyquinone. Dihydroxyquinone mono-anilide.

If the boiling be continued until no more smell of aniline can be perceived, the solution contains the potassium salt of monochlorodihydroxyquinone. The author discusses the constitution of these compounds at great length without, however, arriving at any definite formulae.

On treating anilidoxyhydroxyquinone-anilide or anilidoxyhydroxyquinone with very dilute caustic potash until the evolution of aniline ceases, the potassium salt of Nietzki's paradihydroxyquinone is formed. The same body is obtained from diamidoquinone by treating it with alcoholic sulphuric acid from tetramethyldiamidoquinone by treatment with caustic alkalis. If, instead of alkalis, hydrochloric acid be used, dimethylamidohydroxyquinone—

is the first product of the reaction.—A. L.

*On some Derivatives of 1:3 Dichloronaphthalenes.* P. T. Clève. Ber. 23, 954—958.

THE most convenient method for the preparation of this compound is to form it from dichloronaphthylamine. It is purified by distillation with steam, and boils at 289° C., at a pressure of 775 mm.

If a solution of this body in chloroform be saturated with chlorine at ordinary temperatures, and then treated with alcohol, a quantity of white needles are precipitated, melting after crystallisation from hot alcohol at 92° C. The trichloronaphthalene, C<sub>10</sub>H<sub>7</sub>Cl<sub>3</sub> [1:3:4] is identical with the compound formerly obtained from dichloronaphthol and phosphorus pentachloride.

On oxidation of dichloronaphthalene with 2½ parts of chromic acid, monochloronaphthoquinone, melting at 115° C. and crystallising in long yellow needles, and phthalic acid, were obtained. The author prepared from the quinone, anilidomonochloronaphthoquinone (dark red needles, melting at 207° C.), Chloronaphthoquinone-oxime, C<sub>10</sub>H<sub>7</sub>ClO.NOH (yellowish needles melting and decomposing at 200° C.).

Ordinary nitric acid, sp. gr. 1.2, does not act on this dichloronaphthalene; a mixture of nitric acid and sulphuric acid forms two dinitro-compounds; with an excess of nitric acid trinitrodichloronaphthalene is produced.

*Dinitrodichloronaphthalene I.*, C<sub>10</sub>H<sub>4</sub>(NO<sub>2</sub>)<sub>2</sub>Cl<sub>2</sub>.—If the mixture of the nitration product be crystallised from glacial acetic acid, fine nearly colourless needles are obtained, containing acetic acid of crystallisation. The compound melts at 150° C., and is soluble in benzene. From the

mother-liquor the isomeric *Dinitrodichloronaphthalene II.*, crystallises in small white needles, melting at 158° C. Both compounds yield on further nitration—

*Trinitrodichloronaphthalene*, C<sub>10</sub>H<sub>3</sub>(NO<sub>2</sub>)<sub>3</sub>Cl<sub>2</sub>.—Pale yellow needles, melting at 178° C. It forms with ammonia,

*Anidochlorotrinitronaphthalene*, C<sub>10</sub>H<sub>3</sub>(NH<sub>2</sub>)Cl(NO<sub>2</sub>)<sub>3</sub> (yellow needles melting at 252° C.) and with aniline,

*Anidochlorotrinitronaphthalene*—

(red flakes melting at 230° C.), whilst alcoholic caustic soda converts it into *trinitrochloronaphthol*—

crystallising from glacial acetic acid in pale yellow needles, melting and decomposing at 156° C.—A. L.

*1:4 Nitronaphthalenesulphonic Acid.* P. T. Clève. Ber. 23, 958—961.

On titration of the sodium salt of naphthalene-α-sulphonic acid, three isomerides are obtained: 1:5, 1:8, and 1:4 nitronaphthalenesulphonic acids. The latter yields on reduction naphthionic acid. To prepare these bodies the author proceeded in the following way: 1 kilo. of the sodium salt is gradually added to a mixture of 750 grms. of nitric acid of sp. gr. 1.4, and of 500 grms. of nitric acid of sp. gr. 1.5. After dilution the calcium salts are formed, and their solution is filtered whilst hot. On cooling, the calcium salt of the 1:5 acid crystallises out. The mother-liquor is concentrated, and the calcium salts decomposed with sulphuric acid. On evaporation small crystals of the 1:5 acid are obtained. The mixture of the remaining acids is converted into their potassium salts and then by means of phosphorus pentachloride into sulphonic chlorides. The first fractions yielded nearly pure 1:5 nitronaphthalenesulphonic chloride, whilst the remaining formed a mixture of the 1:5 and 1:4 chlorides, from which the latter was obtained by crystallisation from benzene and petroleum spirit, and melted at 99° C. The 1:8 acid forms the most soluble salts, and is contained in the mother-liquor after the 1:5 and 1:4 salts have crystallised out. The author describes the following compounds of the 1:4 acid:—

*Potassium Nitronaphthalenesulphonate*—

*Sodium Nitronaphthalenesulphonate*—

*Calcium Nitronaphthalenesulphonate*—

*Barium Nitronaphthalenesulphonate*—

*Silver Nitronaphthalenesulphonate*—

*Lead Nitronaphthalenesulphonate*—

*The Ethyl Ester*, C<sub>10</sub>H<sub>6</sub>NO<sub>2</sub>SO<sub>3</sub>C<sub>2</sub>H<sub>5</sub>, melting at 98° C.

*The Methyl Ester*, C<sub>10</sub>H<sub>6</sub>NO<sub>2</sub>SO<sub>3</sub>CH<sub>3</sub>, melting at 117° C., and the amido compound, C<sub>10</sub>H<sub>6</sub>NO<sub>2</sub>SO<sub>2</sub>NH<sub>2</sub>, melting at 188° C. The latter yields on reduction with glacial acetic acid, hydriodic acid and phosphorus, and on precipitation of the solution with ammonia, the amide of naphthionic acid, melting at 206° C. Its formula is C<sub>10</sub>H<sub>6</sub>NH<sub>2</sub>(SO<sub>2</sub>NH<sub>2</sub>). —A. L.

*On 1:8 Chloronaphthalenesulphonic Acid.* P. T. Clève. Ber. 23, 962—963.

On treating the potassium salt of 1:8 nitronaphthalenesulphonic acid with phosphorus pentachloride a very

violent reaction sets in. To moderate the reaction, the salt was diluted with carbon bisulphide, and then phosphorus pentachloride added. Nitrous acid vapours escaped, and 1 : 8 chloronaphthalenesulphonic chloride, melting at  $101^{\circ}\text{C}$ ., was obtained. On boiling with barium hydrate, the barium salt,  $(\text{C}_{10}\text{H}_6\text{ClSO}_3)_2\text{Ba} + 2\text{H}_2\text{O}$ , was formed. There are further described the *Ethyl ester*,  $\text{C}_{10}\text{H}_6\text{ClSO}_3\text{C}_2\text{H}_5$ , melting at  $67^{\circ}\text{C}$ .; the *Methyl ester*,  $\text{C}_{10}\text{H}_6\text{ClSO}_3\text{CH}_3$ , melting at  $70^{\circ}\text{C}$ .; and the *amide*,  $\text{C}_{10}\text{H}_6\text{ClSO}_2\text{NH}_2$ , melting at  $196^{\circ}\text{--}197^{\circ}\text{C}$ .—A. L.

*On Ethylxylenes.* J. Stahl. Ber. 23, 988—991.

By the action of ethyl bromide and sodium on the monobromo derivatives of the three isomeric xylenes, there were obtained—

*Ethylmetaxylene*,  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{CH}_3)(\text{C}_2\text{H}_5)$  [1 : 3], boiling at  $185^{\circ}\text{--}186^{\circ}\text{C}$ ., and forming a sulphonic acid on treatment with concentrated sulphuric acid. With a mixture of nitric and sulphuric acid, *Trinitro-ethylmetaxylene*,  $\text{C}_6(\text{NO}_2)_3(\text{CH}_3)_2\text{C}_2\text{H}_5$ , melting at  $127^{\circ}\text{C}$ ., is prepared.

*Tribromo-ethylmetaxylene*, melting at  $94^{\circ}\text{--}95^{\circ}\text{C}$ ., is the product of the action of an excess of bromine on the hydrocarbon. On oxidation with dilute nitric acid, *Nitrylic acid*,  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{CH}_3)(\text{CO}_2\text{H})$  [1 : 3 : 4], melting at  $125^{\circ}\text{C}$ ., is formed.

*Ethylparaxylene* boils at  $185^{\circ}\text{C}$ ., and yields a sulphonic acid, which, on fusing with caustic potash, is converted into *Ethylparaxyleneol*, melting at  $37^{\circ}\text{C}$ ., and boiling at  $245^{\circ}\text{C}$ . Ferric chloride does not act on its aqueous solution, but produces in its alcoholic solution a deep green colouration. On oxidation of the hydrocarbon, isoxilylic acid,—

was obtained.

*Ethylorthoxylene*,  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{CH}_3)(\text{C}_2\text{H}_5)$  [1 : 2 : 4], boils at  $187^{\circ}\text{--}188^{\circ}\text{C}$ ., and is easily converted into a sulphonic acid, forming a *trinitro derivative*, melting at  $121^{\circ}\text{C}$ ., also a *tribromo compound*, melting at  $93^{\circ}\text{C}$ ., and on oxidation *paraxilylic acid*,  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{CH}_3)\text{CO}_2\text{H}$  [1 : 2 : 4], melting at  $163^{\circ}\text{C}$ .

By the action of ethyl bromide on metaxylene in presence of aluminium chloride, two isomerides are obtained: the one before described, ethylmetaxylene—

and—

boiling at  $188^{\circ}\text{C}$ . It forms a sulphonic acid, and, on oxidation, *mesitylenic acid*.—A. L.

*On Amidochrysene.* E. Bamberger and C. Burgdorf.

Ber. 23, 1006—1007.

THE authors obtained amidochrysene by reducing nitrochrysene with tin and hydrochloric acid, thus obtaining a tin double salt.—A. L.

*Dyewoods and Extracts, their Use and Abuse.* L. Bruehl. Textile Colourist, 1889, 125, et seq. (This Journal 1889, 612—618.)

*Fustic*.—Fustic is the product of the tree, *Morus tinctoria*, which is indigenous to the West India Islands, especially Jamaica and Cuba, Mexico and Brazil. It contains two different dyestuffs, viz.: morin or moric acid, and maclurin or moritannic acid. Maclurin, or moritannic acid, is readily soluble in water: 6 parts cold water, or 2·18 parts boiling water dissolve 1 part maclurin. Morin is nearly insoluble in water (1 part morin dissolves in 4,000 parts cold water or in 1,060 parts boiling water), readily soluble in caustic alkalis and in alkaline borates and phosphates, and is

precipitated from such solutions by acids. Morin is also readily soluble in alcohol and ether.

The kinds of fustic most frequently offered in the European market are: Tampico fustic, Tuspan fustic, Yellow Pernambuco wood, East India fustic, San Domingo fustic, which denomination applies to all yellow woods from the West Indies besides; finally, Cuba fustic.

The commercial classes of fustic greatly differ from each other in their contents of dyestuff, the brands Cuba, San Domingo and Tampico being considered the best. The so-called East India fustic of commerce is very poor in extract, and scarcely pays for working; it is, therefore, principally used for fine cabinet work.

It is generally held that Cuba wood, especially the brand "Cuba Coast" is to be considered the best. It has been found that the quantity of extract contained in the wood is very variable, and that in the different logs from the same cargo of wood as many different percentages of dyestuff extract may be found, which with good wood range from 6 to 18 per cent. The average yield of the wood ought to be 10—12 per cent., and only seldom woods are encountered which in industrial working give a yield of 15—18 per cent. Considering the structure of the wood it is particularly necessary with fustic, on taking samples, to be very cautious in judging it, because different parts of the same tree often yield very different quantities of extract. In the interior of the wood often deposits of a yellow powder are found, and of a red resinous matter, which substances are very rich in colouring matter, indeed, they are nearly pure dyestuff. If it happens in taking a sample, that a portion of the wood is struck, where there is such accumulation of colouring matter, a yield of over 40—60 per cent. extract is easily obtained. A light yellow colour and numerous red veins appearing in the structure of the wood, are regarded as general characteristics of a good fustic.

The analyses of various brands of fustic which follow, illustrate the difference between the quantity of extract and quantity of colouring matter.

Name of Wood.	Water.	Extract.	Dyestuff.	Ash.
	PerCent.	PerCent.	PerCent.	PerCent.
Tampico fustic, 1884 .....	15·2	14·6	11·32	1·4
Cuba fustic, 1884 .....	14·3	15·35	12·71	0·96
Maracaibo fustic, 1885 .....	14·31	13·64	10·91	1·33
San Domingo fustic, 1887 ..	12·73	12·1	10·46	0·99
Cuba fustic, 1886 .....	10·8	13·17	9·09	1·37
Cuba coast, 1887 .....	10·3	14·32	11·4	1·45
Cuba coast, 1885 .....	9·7	15·81	13·67	1·03
Tuspan fustic .....	14·12	13·5	11·68	1·00
East India fustic .....	14·6	6·19	4·00	2·38

This table shows very distinctly that the quantity of extract obtained from a wood is not sufficient evidence as to the tinctorial value of the latter, since there are woods found which with a yield of extract of 13·64 per cent. represent a quantity of 10·91 per cent. contained therein (Maracaibo), while Cuba 1886, yielding 13·17 per cent. extract represents 9·09 per cent. dyestuff. On the other hand it can also be observed that there are differences between different crops of the same kind of wood. If we compare the different cuttings of Cuba fustic, we find the following:—

Cuba.	Extract.	Colouring Matters.
	Per Cent.	Per Cent.
1884	15·35	12·71
1885	15·81	13·67
1886	13·17	9·39
1887	14·32	11·14

These figures demonstrate plainly how the difference between the quantities of extract matter and of colouring matter contained in a wood operates in practice. Persons who have not all the facilities at their disposal to carry out an accurate examination of the wood, ought never to estimate the tinctorial value from the yield of extract; they will arrive at a more correct estimate by making a dye-trial.

The *morin* of fustic being nearly insoluble in water, it is unable to diffuse in the dye-baths and thus to be utilised. For dyeing practice, therefore, only the quantity present of *maclurin* is of importance, and this ranges between 6 and 12 per cent. Only with few woods a higher tinctorial value in *maclurin* is obtained, unless they are lixiviated by the aid of substances which are solvents for *morin*. In this case the yield of the wood will appear a little higher; in the dyeing process, however, such wood extracts will not be able to give results corresponding with the yield of extract, but will always, in trial dyes with equal quantities of extract, give inferior results with extracts which are rich in *morin*.

After carrying out the processes most used in Germany and England with various classes of wood and extracts, the author arrived at the general conclusion that the addition of borax in the extraction, in other words, the presence of borax in the extract, is of no use whatever.

Of equally doubtful value is the addition of carbonate of soda to the extraction liquids, which is practised in some extract works. The author has often pondered the utility of this addition, and on undertaking experiments in this direction has obtained no results which would practically justify the addition of soda. The extracts produced with the addition of soda show a little redder colour. It is not the alkaline carbonates, but only the caustic alkalis which can effect a more rapid solution of the fustic dyestuffs.

While the extract manufacturer buys his fustic in sticks or logs, the product is offered to the dyer in chips or in powder. As regards the way of chipping, there are sold in Germany cross-cut chips, that is, such as are produced by cutting the log in a perpendicular direction to its axis (across the grain) and long-cut chips, produced by cutting parallel to the axis, in the direction of the structure of the fibre (with the grain). Many dyers prefer the long cut for good reasons, and about the usefulness of the long cut there can be said at least as much *pro* as *contra*. The advantage of the long cut is, that it is softer to the feel and gives not so much powder as the cross cut. The pieces and yarns dyed with such wood are easier to clean from the adherent particles of wood; and there is no danger of tearing the pieces upon the washing machines, which can very readily occur with cross-cut chips, unless they are very fine. A disadvantage of the long cut, however, and which is of a very serious character, is that it is difficult to extract, and when the thickness of the chip is over 0.5 mm., considerable quantities of residual colouring matters remain in the chip, which represent no inconsiderable loss in dyestuff for the dyer. The manufacturers of extract, therefore, always use cross-cut chips for extraction.

There are inserted here the results of a comparative experiment of extraction with cross-cut and long-cut chips. The extraction was carried out in a high pressure apparatus with only  $\frac{1}{2}$  atm. pressure. The quantity of water was calculated in the proportion of 1:3.

#### EXTRACTION OF CROSS-CUT CHIPS. 10 KILOS. WOOD.

4	Extract 0.1° B.	66	281 grms.	Per Cent. 2.81
	Total .....	1,798	Yield ....	17.980
	Total contents of the wood .....			18.406

After the lixiviation an average sample was taken from each sample of wood and dried, and 100 grms. of each completely extracted with distilled water in Schroedler's extractor, when the cross cut still gave 0.426 per cent. residue, and the long cut 2.81 per cent., whereby the total yield of one wood (cross cut) amounts to 18.406 per cent., that of long cut to 18.13 per cent. Considering the unavoidable losses occurring by the extraction in the experimental apparatus, in evaporating the decoctions, &c., the wood was therefore considered of equal value.

Herefrom results a difference of 2.374 per cent. from the extractions which are obtainable in industrial working, that is, for the dyer who uses long-cut chips, a loss of 2.374 kilos. extract for every 100 kilos. chips which, taking the price of extract at 140 mk. per 100 kilos. extract, represents in cash a loss of 3 mk. 32 d. Besides, the price of long-cut chips is higher than that of cross cut. Cuba long-cut fetching, in 1888, 15.50 mk. per 100 kilos., the loss of 3.32 mk. represents about 20 per cent. of the total value of the wood, which loss, considering the present low dyeing prices, is a matter which requires due consideration.

Similar to the case of logwood is that of fustic which is sold in the form of chips. The quality and purity of these woods is very variable, and principally depends upon the price. Fustic in a finely reduced condition has also the property of absorbing water in considerable quantity. The normal proportion of water contained in the wood ranges from 12 to 15 per cent., while chips may often contain 18–24 per cent. of water and no noticeable alteration of it can be discovered, particularly when presented in the shape of long-cut. It is easy to understand that this property of the woods is largely taken advantage of to the disadvantage of the consumer, who must buy and pay gross for net according to the weight indicated by the bill of lading. Another largely practised adulteration is that with woods of inferior quality, such as chestnut wood, waste of quercitron bark, turmeric powder, and finally with fustic chips which have already been extracted. Of the latter adulteration the most extensive use is made where the object is to blind the consuming dyer with a low price and fine cut. The author has met with cases where the chipped wood was mixed with about 40 per cent. of extracted chips and about 5 per cent. turmeric powder. Such a mixture was then sprinkled with water containing about 5 per cent. of soda and left in a pile for several days, using the precaution to several times shovel it over. By this treatment the wood assumes a uniform colour and the lixiviated chip could only with difficulty be distinguished from the non-lixiviated even by means of the microscope.

It is impossible, even with the most careful extraction of the woods, to obtain the whole quantity of colouring matter contained in the wood, but there always remains in the chips a part of the dyestuff soluble in water and, with a well conducted extraction, about 0.5 to 1 per cent. must be allowed for this loss. This residue, however, does not for the extract-maker represent 0.5 or 1 per cent., but with an effective percentage of 15 per cent. extract contained in the wood, a loss of 3.3 per cent., or otherwise 6.6 per cent. of the value of his wood in extract; it is, therefore, a matter of course, that ways and means are sought for to reduce this loss to a minimum. Besides the additions of borax and soda which, as stated, do not answer the purpose, the method of lixiviating under high pressure is applied. As

in the case of logwood, in this case also higher yields in extract are obtained, but, unless this extraction is carried out with great caution, it will be at the cost of the quality of the extract. It is an undisputed fact that by working with high pressure, the last traces of the dyestuff soluble in water can be extracted; but there enter also into the extract other extractive matters present in the wood together with particles of wood mechanically carried over, which do not contribute to the increase of the tinctorial value of the extract. A comparative trial dye with extracts obtained with high pressure in greater amount, as against such as had been produced without high pressure, showed in the shades the same graduation but in inverse proportion to the pressure, that is, it became manifest that the extract which had been produced without pressure gave the best results, and the extracts prepared with pressure gave dyes which were weaker in the same ratio as the pressure and yield increased. The experiment of treating the respective extracts with alcohol was now tried, the residue which had been left was dissolved in water and allowed 48 hours to settle, when a sediment was deposited which proved to be cellulose; and cellulose could also be discovered, both in the aqueous and alcoholic extract, and that in quantities increasing proportionally to the pressure applied in the extraction.

**Sumac.**—The commercial sumac is obtained from the various species of *Rhus*, such as *Rhus coriaria*, *Rhus cotinus*, *Rhus glabrum*, *Rhus canadensis*, *Rhus typhinus*, *Rhus pentaphyllum*, and *Rhus uva ursi*. The principal species sold in the European markets and most valued are the Sicilian sumac (*Rhus coriaria*) and that from Central Italy (*Rhus cotinus* and *Rhus coriaria*), which plants are not only collected in Central Italy, but also in Dalmatia, Istria, and Montenegro, and are commercially known as Fiume sumac. Besides, there is Spanish sumac and French sumac. Of the latter, four brands are distinguished which, however, belong all either to *Rhus coriaria myrtifolia* or *Rhus pentaphyllum*, according to the regions where found, as Fauvis sumac (Département du Var), Redoul sumac (Gironde), Pudis sumac (South France), and Dongère sumac (Rhône). Finally, American sumac is obtained from various species of *rhus*, the best being that derived from *Rhus glabrum*, *Rhus canadensis*, and *Rhus typhinus*. More recently another tannin-bearing plant is often offered in the market as sumac under the name of Swedish sumac. Although of very inferior quality, this product, obtained from *Arbutus uva ursi* and *Vaccinium vitis*, is fraudulently sold for sumac, the deception being easy to carry out, as both leaves and twigs of these plants very much resemble those of the various species of *rhus*. Only a close examination shows the difference.

The principal value of sumac consists in the proportion of real tannin which it contains, or rather a tannic acid which, though not identical with the tannic acid of nutgalls, produces similar reactions as the latter, or possesses similar properties. The quantity of dyestuff contained in sumac plays in practice only a subordinate part.

It seems that there are several tannic acids contained in sumac, some of which resemble the tannic acid of nutgalls (tannin), while the others are similar to gallotannic acid. The former are designated as actual value in tannin of sumac, the latter give the so-called gallotannic value. Of actual value for the tanner and dyer is only the quantity of tannin contained in sumac, because only this class of tannic acid compounds has the property of forming insoluble salts with metallic oxides, and thus serving for the fixation of mordants, and as mordants for aniline and other dyestuffs. About the value of gallotannic acid in dyeing, opinions are greatly divided.

The tannic acids readily soluble in water are pretty completely precipitated from their solutions by various reagents, as by sulphuric acid, many salts and solution of glue. Of all these reagents, however, only the solution of glue has been adopted for practical use according to the propositions of Meunier and Warrington, who invented a method of determining tannin by titration. This method was declared insufficient by G. Mueller, who demonstrated that an exact quantitative analysis by this process is impossible, as the precipitate formed does not perfectly separate out, and the

solution remaining turbid prevents the observation of the end of the reaction. Although an addition of alum in some degree removes this difficulty, this method, despite all modifications added to it by Mueller, F. Schulze, and others, remains inaccurate. Loewe showed that many tannic acid bearing materials, sumac included, contain besides it, other substances soluble in water, which act like tannin, and thereby render the correctness of the analysis problematical.

Since thus the method of precipitating tannic acid with glue was done away with, scientists turned their attention to the use of metallic salts capable of precipitating tannic acids as insoluble precipitates, and H. Fleck pointed out the property of acetate of copper of completely precipitating tannic acid as well as gallotannic acid. Since cupric gallotannate is perfectly soluble in a solution of ammonium carbonate, while cupric tannate is insoluble in this reagent, the road towards exact examination again seemed to have been found. But this method was also controverted by many chemists, and later on modified by Eder, Hayer, and others, though finally rejected as insufficient.

Hardtke introduced ferric acetate instead of the cupric salt as precipitating agent, but this method of titration as well as that of Gerland (with solution of tartar emetic) proved inaccurate. Only Hammer succeeded in finding the correct way to determine tannin. He based his method upon the property of tannic materials to give insoluble precipitates with the animal skin. Although Hammer's original process was very complex, it gave in combination with other methods the basis for the determination of the tannins.

The final decisive step towards improvement was taken by Loewenthal. This chemist based his method upon the oxidisability of the tannins by potassium permanganate or chloride of lime, using a surplus of indigo carmine as indicator. This method, combined with that of Hammer, forms at present the principal basis of all determinations of tannin, and the improvements introduced in the combined (or, as it is called, improved) method of Loewenthal only concern the way of proceeding, but not its principles. (This Journal, 1884, 82 and 524; also 1885, 263.)

In order, now, to determine the value in tannin, a certain quantity of the substance to be examined is weighed off, say 5 grms. sumac, perfectly extracted with boiling water, and the decoction made up to 1 litre. For the test, 20 ccm. of the decoction are placed in a beaker, and 750 ccm. distilled water, 10 ccm. of 1·10 normal sulphuric acid, and 20 ccm. solution of indigo carmine (of known percentage) are added. Then the oxidising liquid, in this case permanganate of potash (3 litres water and 4 grms.  $\text{KMnO}_4$ ) is introduced from a burette until the original blue colour of the solution to be titrated is changed to straw yellow. According to the quantity of solution of permanganate the total value in tannin and gallotannic acid is then calculated.

The author calls attention to the fact that it is an error to believe that the tannin of sumac is identical with the tannin of nutgalls or of other tanners' plants. On the contrary, nearly every tannin-bearing plant has a specific tannin of its own, which resembles the tannic acid of nutgalls only in the properties of giving with certain metallic salts precipitates which are insoluble in water, and of tanning the animal skins to be precipitated by the latter.

It was found that from the yield of extract of a certain kind of sumac no conclusion as to its value in tannin can be drawn. While a yield of 30 to 40 per cent. extract is by no means a rare occurrence, no sumac was discovered that contained over 25 per cent. actual tannin. Good sumac averages 10—15 per cent. actual tannin, its value in extract ranging from 30—40 per cent. It is therefore a great mistake if, for the valuation of a given kind of sumac, simply a decoction of it with a certain quantity of water is made, its specific gravity found, and the estimation of the value of the test-sumac made accordingly. This method may have special value for the extract maker, but to the dyer and tanner it affords absolutely no reliable indication of the value of the article; and yet this method of valuation is practically applied in many dyehouses and tanneries.

In the commercial sumacs, besides sand and yellow earth (loam) sometimes up to 15 per cent. refuse of various tanning barks of inferior value, such as chestnut wood,

quebracho wood, also quercitron bark and waste of fustic, are found as adulterants. As regards the latter two adulterations, it seems that their object is to produce the colour peculiar to the concomitant dyestuff which is contained in sumac, especially when the sumac in question either naturally contains but little of this accompanying dyestuff, or when its colour has been degraded by other additions or by fermentation of the leaves in a damp store. But as the principal value of sumac, not to say its only value, depends upon its content of tannin, the additions of other colouring bodies appears to be a useless waste of the latter. Sand and loam go mostly together with waste of chestnut wood used for adulteration; probably the tannin contained in chestnut wood (which, besides, is about 50 per cent. cheaper than sumac) is to compensate the deficiency in tannin which is produced by the admixtures of loam and sand. What trouble such admixture of another tannic acid bearing material together with a dark colouring companion dyestuff may cause the dyer, anyone may judge by contrasting a dye with chestnut or quebracho with a sumac dye.

#### PATENTS.

*Improvements in and relating to the Manufacture of Colouring Matters.* H. H. Lake, London. From A. Leonhardt and Co., Mühlheim-on-the-Maine, Germany. Eng. Pat. 4387, March 29, 1886. Amended December 8, 1887. (Second Edition.) 6d.

THE subject-matter of this patent has already been abstracted (this Journal, 1887, 507). In the original specification the acid obtained by the action of caustic soda and zinc dust on *p*-nitrotoluenesulphonic acid was designated a "new anidosulpho acid." This is amended to a "disulpho acid of diamidostilben." The other amendments provide for varying the shades of the dyestuffs obtained, either by combining the tetrazo-compound from diamidostilbene disulphonic acid with dissimilar phenols or amines, or by mixing the various dyestuffs themselves.

—T. A. L.

*The Manufacture of Azo-Dyes and of Materials therefor.* B. Willcox, London. From "The Farbenfabriken vormals Friedrich Bayer and Co.," Elberfeld, Germany. Eng. Pat. 7802, May 9, 1889. 8d.

THE *o*-benzidine disulphonic acid, obtained by reducing *m*-nitrobenzene sulphonic acid in an alkaline solution and transforming the hydrazo-compound into the diamido-compound, gives tetrazo dyestuffs which do not dye unmordanted cotton from an alkaline bath. It has, however, been discovered that by heating the disulphonic acid with caustic alkalis at a pressure of 30–40 atmospheres and at 150°–300° C., it is converted into diamidodiphenylene oxide, which when diazotised and combined with phenols and amines or their sulphonic acids gives direct dyestuffs for cotton. In like manner the *o*-tolidine disulphonic acid obtained from *o*-nitrotolylene-*m*-sulphonic acid can be converted into diamidoditolylene oxide.—T. A. L.

*Manufacture of a New Colouring Matter of the Induline Series.* O. Imray, London. From "The Farbwerke vormals Meister, Lucius und Brüning," Höchst, Germany. Eng. Pat. 7857, May 10, 1889. 4d.

A METHOD for obtaining from the induline melt a bluish-violet colouring matter having the formula  $C_{21}H_{18}N_4$ , dependent upon the fact that only this base is capable of forming a stable acetate. 5 kilos. of aniline, 3.9 kilos. of aniline hydrochloride, and 2 kilos. of amidoazobenzene are heated together. The melt is then boiled two or three times with a large quantity of water and filtered. The filtrates are treated with hydrochloric acid and the precipitate thus obtained filtered, pressed, and dried at 70°–80° C. This mixture is then heated with sodium acetate under pressure, in which case the acetate of the base  $C_{21}H_{18}N_4$  remains in solution, and after filtration can be dried down. As an alternative method the hydrochlorides obtained above are decomposed with dilute caustic soda, washed, and the mixture of the bases whilst still moist boiled in an aqueous

solution with acetic acid, filtered and evaporated to one-fourth of its volume, when the acetate crystallises, forming blue leaflets with a brown lustre. In place of acetic acid, tartaric, citric, or levulic acid may be employed.—T. A. L.

*Improvement in the Manufacture of Amidophenols.* H. H. Lake, London.—From A. Leonhardt and Co., Mühlheim-on-the-Maine, Germany. Eng. Pat. 8156, May 16, 1889. 4d.

A PROCESS for producing *m*-amidophenol and its alkylated derivatives by heating resorcinol with ammonia or a fatty amine at about 200° C. under pressure in an aqueous solution.—T. A. L.

*Improvements in or connected with the Manufacture of Azo-Colouring Matters for Printing and Dyeing.* B. Willcox, London. From "The Farbenfabriken vormals Friedrich Bayer and Co.," Elberfeld, Germany. Eng. Pat. 8299, May 18, 1889. 8d.

A PROCESS for combining (1) the diazo-compounds of amido carboxylic acids, such as the amido benzoic acids, amido hydroxybenzoic acids, amido phthalic acids, and the sulphonated amido cresol carboxylic acids, &c., with 1:8 and 1:2 di-oxy-naphthalenes and  $\alpha$ - and  $\beta$ -naphthol carboxylic acids; (2), the diazo-compounds from the amido benzoic acids, the amido phthalic acids, and the amido anisic acids with salicylic acids and cresol carboxylic acids; and (3) the diazo-compounds of the amido carboxylic acids referred to in (1) with one molecule of  $\alpha$ -naphthylamine, rediazotising the amido azo-compounds and combining them with amines, phenols, and their sulphonic and carboxylic acids. The dyestuffs thus formed are to be used for dyeing and printing, generally with the aid of mordants, although some of them are capable of dyeing wool directly. The colours are said to be absolutely fast to soap, milling, and sunlight. The shades obtained vary from a bright yellow and brown to a deep blue-black according to the components.—T. A. L.

*Improvements in the Manufacture of Colouring Matter and of Leuco Bases employed therein.* B. Willcox, London. From "The Farbenfabriken vormals Friedrich Bayer and Co.," Elberfeld, Germany. Eng. Pat. 8673, May 24, 1889. 8d.

THE red colouring matters formed according to this invention are obtained from *m*-amidophenol, its alkylated derivatives and hydroxydiphenylamine, by heating them with a variety of substances with or without a dehydrating agent. The patent is divided into three parts, as follows:—

I. Leuco bases of the triphenyl methane series are obtained by condensing benzaldehyde and its derivatives with the substances mentioned above according to the general equation—

The substance thus obtained when heated with a dehydrating agent is represented as decomposing in the following manner—

This equation is represented somewhat differently in the provisional specification. The products obtained dye wool and mordanted cotton the same shade as rhodamine and show a brilliant fluorescence on silk.

II. Red basic colouring matters are formed by heating methylene chloride, bromide or iodide, acetone, or chloroform with two molecules of benzil or nitrobenzil and four molecules of an alkylated *m*-amidophenol.

III. Similar colouring matters are also obtained by heating the di-alkylated *m*-amidophenols with phosgene under pressure at 180°, and treating the resulting tetra-alkylated di-hydroxydiamidobenzophenones with dehydrating agents.

Finally, a number of substances are mentioned, which when heated with an alkylated *m*-amidophenol at various temperatures yield red basic colouring matters, such as paraldehyde, unsymmetrical diphenyl-trichloro-ethane or diphenyl-dichloro-ethylene, benzal chloride, benzotrichloride, formic acid, or a mixture of glycerol and oxalic acid.

—T. A. L.

*Improvements in the Manufacture of Basic Colouring Matter.* B. Willcox, London. From "The Farbenfabriken vormals Friedrich Bayer and Co.," Elberfeld, Germany. Eng. Pat. 8750, May 27, 1889. 8d.

BLUE colouring matters are obtained, according to this invention, by combining diazo-compounds or their sulphonie acids with the alkylated derivatives of *m*-amido-phenol and subsequently heating these products with  $\alpha$ -naphthylamine or an alkylated derivative thereof in presence of a suitable solvent at 150°–200° C. The reaction may also be performed in another way by combining the diazo-compounds with  $\alpha$ -naphthylamine or its alkylated derivatives and heating these compounds with alkylated *m*-amido-phenols as above. The second phase of the reaction which takes place is expressed as follows:—"One molecule of benzene-azo-dimethyl-*m*-amido-phenol + one molecule of  $\alpha$ -naphthylamine gives aniline + blue colouring matter." The following example illustrates the process. About 12 kilos. of benzene-azo-di-methyl-*m*-amido-phenol, 6 kilos. of hydrochloric acid of 33 per cent. HCl, 9.5 kilos. of  $\alpha$ -naphthylamine hydrochloride, and 9 kilos. of glycerol are stirred into a paste and heated to 160°–165° C. The melt finally turns blue, gas is evolved and the colouring matter separates out in lustrous green laminae. The whole melt is then poured into about 150 litres of water, and the colouring matter which precipitates is purified by crystallisation from water in which the hydrochloride is sparingly soluble in the cold. It is tolerably soluble in cold alcohol with a blue colour, having a dark red fluorescence, and on the addition of an alkali gives a base soluble in alcohol and ether with a red colour and a yellowish brown fluorescence. The sulphate is readily soluble in hot water.—T. A. L.

*Colouring Matter of the Oxyketone Group, suitable for Dyeing and Printing with the Aid of Mordants.* J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 9427, June 5, 1889. 4d.

THIS is an extension of Eng. Pat. 8373, of 1889 (this Journal, 1890, 497), and describes the preparation of tetra-hydroxy-phenyl-naphthyl ketone. About 100 parts by weight of gallic acid are dissolved in about 400 parts by weight of  $\alpha$ -naphthol at 230° C. and 4 parts by weight of zinc chloride are carefully added to the solution. After the reaction has ceased the mass is allowed to cool to about 100° C., when the excess of  $\alpha$ -naphthol is extracted with benzene. The dyestuff is then dissolved in alcohol and precipitated by pouring into water, when it separates in yellowish green scales. The substance does not melt below 200° C., and dyes cotton mordanted with alumina a greenish yellow, and wool mordanted with alumina a brownish yellow.—T. A. L.

*A New or Improved Manufacture of Beta-Naphthol Carbon Acid.* J. Y. Johnson, London. From F. von Heyden Nachfolger, Radebeul, Germany. Eng. Pat. 9612, June 11, 1889. 4d.

The production of a  $\beta$ -naphthol carboxylic acid has already been described in Eng. Pat. 6134 of 1885 (this Journal, 1885, 531), and Eng. Pat. 8155 of 1886 (this Journal, 1886, 482). The acid thus obtained melting at 157° C. is very unstable and decomposes easily into  $\beta$ -naphthol and carbonic acid. It has been found that by the action of carbonic acid under pressure on the alkaline salts of  $\beta$ -naphthol at 200°–250° C. a stable acid of a yellow colour is produced melting at 216° C.—T. A. L.

*Production of Oxy-sulphonic Acids of Naphthalene.* O. Imray, London. From "The Farbwerke vormals Meister, Lucius und Brüning," Höchst, Germany. Eng. Pat. 9642, June 11, 1889. 6d.

THE  $\beta$ -naphthol disulphonic acids R and Y (described in Eng. Pat. 1715 of 1878) and the  $\beta$ -naphtholtrisulphonic acid of Eng. Pat. 2544 of 1882, when heated with caustic alkalis, yield oxy-sulphonic acids of naphthalene, which form azo-dyestuffs when combined with diazo-compounds.

—T. A. L.

*Improvements in the Production of Colouring Matters from Oxy-sulphonates of Naphthalene.* O. Imray, London. From "The Farbwerke vormals Meister, Lucius und Brüning," Höchst, Germany. Eng. Pat. 9643, June 11, 1889. 4d.

VIOLET to bluish-black colouring matters for wool are produced by combining the dioxynaphthalene disulphonic acid described in Eng. Pat. 9642 of 1889 (see preceding abstract) with the diazotised amido azo-compounds obtained by combining diazotised amidosulphonic acids with  $\alpha$ -naphthylamine. In the example given, *o*-toluidine sulphonie acid is diazotised and combined with  $\alpha$ -naphthylamine. The product thus obtained is re-diazotised and combined with dioxynaphthalene disulphonic acid in presence of sodium acetate. Still bluer shades are obtained by substituting naphthylamine sulphonie acids for the *o*-toluidine sulphonie acid.—T. A. L.

*Improvements in the Production of Colouring Matters.* H. H. Lake, London. From K. Oehler, Offenbach-on-the-Maine, Germany. Eng. Pat. 11,000, July 9, 1889. 6d.

Two series of brown colouring matters are obtained (1) by combining the diazo-compounds of the three toluylene diamine sulphonie acids—

with *m*-phenylene diamine and *m*-toluylene diamine; and (2) by combining the so formed intermediate compounds with diazotised amidosulphonic acids. The following example gives the quantities employed: 15 kilos. of the sodium salt of toluylene diamine sulphonie acid—

and 6.9 kilos. of sodium nitrite are dissolved in 500 litres of water, cooled to 0°, and 36 kilos. of hydrochloric acid of 22.5° B. are run in. This diazo solution is then added to 1,000 litres of water containing 21 kilos. of *m*-phenylene diamine sulphate and 25 kilos. of calcined soda. The precipitate forms a dark brown mass, which is filtered, pressed, and dried. It forms a reddish-brown powder, soluble in water with a light yellow-brown colour, and dyes cotton brown from an alkaline bath. As an example of the second series of colouring matters 100 kilos. of the compound obtained above are mixed while still damp with 184 kilos. of diazosulphanilic acid in a sodium acetate solution. The formation of the dyestuff proceeds slowly, and can be accelerated by gently warming. When the reaction is finished the solution is neutralised with soda, boiled, filtered, and precipitated with salt. The dyestuff

forms a blackish powder with a greenish hue. It dissolves in water with a brown colour, which is little affected by alkalis.—T. A. L.

*Manufacture of New Red and Blue Colouring Matters.* O. Imray, London. From "The Society of Chemical Industry in Basle," Switzerland. Eng. Pat. 11,613, July 20, 1889. 6d.

THESE colouring matters are produced by the action of benzotrichloride on the alkylated and phenylated derivatives of *m*-amido-phenol, the former giving reds to violets soluble in water, and the latter bluish-violets to blues, but insoluble in water and requiring to be sulphonated. The reaction is expressed by the following equation:—

where R, R' represent the radicles methyl, ethyl, amyl, benzyl, phenyl, tolyl or naphthyl. A red colouring matter is produced by heating a mixture of 10 kilos. of benzotrichloride, 13 kilos. of dimethyl-*m*-amidophenol and 50 kilos. of sand to 50°–60° C., and finally up to 100°–120° for some hours. The mass is distilled with steam to expel volatile products, and the residue is extracted with 50 kilos. of boiling water and 2 kilos. of concentrated hydrochloric acid. The base is separated by the addition of 20 kilos. of caustic soda lye of 38° B., and purified by redissolving in hydrochloric acid, from which it is precipitated by the addition of zinc chloride and salt, forming long green needles. The base is nearly insoluble in water but easily soluble in alcohol, ether, benzene and toluene. It dyes wool and silk crimson without a mordant, silk showing a yellowish-red fluorescence. Cotton requires a mordant, and is then dyed a rather bluer shade than wool.—T. A. L.

*Manufacture of Blue Colouring Matter.* O. Imray, London. From "The Society of Chemical Industry in Basle," Switzerland. Eng. Pat. 11,848. July 25, 1889. 6d.

TANNIN when heated with aromatic amines forms with them crystalline products (see Schiff, Ber. 15, 7591). These condensation products on heating with nitroso-dimethylaniline hydrochloride give blue colouring matters soluble in alcohol. When heated with sodium bisulphite and alcohol they yield light green needles soluble in hot water, and dye cotton mordanted with tannin, alum or chromium blue to bluish-violet. The condensation products before treatment with bisulphite may be sulphonated, and can then be employed for dyeing blue shades on wool.

—T. A. L.

*Improvements in the Manufacture of Colouring Matters.* H. H. Leigh, London. From R. G. Williams, Albany, U.S.A. Eng. Pat. 3095, February 26, 1890. 6d.

AN extension of Eng. Pat. 12,767 of 1889 (this Journal, 1889, 981; see also this Journal, 1890, 173), in which cotton colours are produced by combining naphthalene-azobiphenylamines and their sulphonie acids with tetrazo bodies, to form intermediate compounds, which can be combined with phenols and amines. In the present invention it is proposed to substitute for the naphthalene-azobiphenylamines the bodies obtained by combining one molecule of diazobenzene, its homologues, or sulphonie acids with one molecule of  $\alpha$ - or  $\beta$ -naphthylamine or its sulphonie acids. The following is one of the examples given: 17.3 lb. of sulphianilic acid are diazotised with 7 lb. of sodium nitrite and 12 lb. of hydrochloric acid of 22° B. The diazobenzene sulphonie acid thus produced is combined with 25 lb. of sodium naphthionate in presence of sufficient

sodium acetate to neutralise the mineral acid present. After some time a brownish-red wool dye is formed, which is combined with tetrazoditolyl from 32 lb. of tolidine sulphate and 14 lb. of sodium nitrite. When all the tetrazo compound has combined, 25 lb. of sodium naphthionate are added. The formation of the colour proceeds slowly, and the whole should be stirred for several days. When dye-tests show no improvement, the temperature is raised to the boil, and sufficient soda lye added to form the sodium salt, which is then precipitated from the liquor by the addition of salt, filtered, pressed, and dried. The colouring matter dyes unmordanted cotton bright red from an alkaline or soap bath, giving a shade similar to that produced when diazo- $\alpha$ -naphthalene sulphonie acid is substituted for the diazo-benzene sulphonie acid mentioned above. Regarding this similarity of shade by substituting benzene for naphthalene, see Eng. Pat. 10,653 of 1889 (this Journal, 1889, 538), and Eng. Pat. 16,493 of 1887 (this Journal, 1888, 619).—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

### PATENT.

*Improvements in the Method of and in Apparatus for Washing or Cleansing Wool and other Textile Fibres, also applicable to the Washing of Clothes.* W. Eastwood, Leeds, and A. Ambler, Bradford. Eng. Pat. 15,153, September 26, 1889. 1s. 1d.

THE wool or other textile fibre which is to be washed is passed through feeding rollers into an open trough, which is preferably set at a slight inclination. A second smaller trough, or a number of such, is fitted into the open one, and by means of an eccentric or other mechanical arrangement, a reciprocating motion is imparted to the same in such a way that the material being washed receives a forward impulse down the open trough towards the squeezing rollers. The smaller troughs are preferably provided with lids, and are perforated at the bottom and sides. Below the washing trough or "sud bowl" there is placed a tank for the reception of the liquor, which, after allowing the sand, &c. to deposit, is pumped again into the trough. It is stated that by the use of this machine the fibres "are not matted or clogged together, as is the case more or less with all fork machines."

The original specification is illustrated with five sheets of drawings.—E. B.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*The Action of Chlorine on Hematoxylin and the Extractive Matter of Logwood.* W. W. Macfarlane and P. S. Clarkson. J. Franklin Inst. 1890, 129, 247–255.

TO increase the dyeing power of logwood liquors and extracts, oxidising agents such as bleaching powder, chlorates, &c. are often added, their action being supposed to consist in the conversion of the hematoxylin into hematein. The authors using the proportions given by Avery (Eng. Pat. 7630 of 1885; this Journal 1885, 585), viz.,  $\text{C}_{16}\text{H}_{11}\text{O}_6 + \text{O} = \text{H}_2\text{O} + \text{C}_{16}\text{H}_{12}\text{O}_6$ , could obtain no satisfactory result; with bleaching powder the result was invariably a dull grey shade of black.

The dyeing power of logwood liquors is however gradually increased to a maximum by exposure to free chlorine, the efficiency of a "42° extract" of dry cut wood was increased 150 per cent. by the action of 9 per cent. of its weight of

chlorine, but any further increase in the quantity of chlorine produced a dull grey shade. The extract obtained from eured wood is similarly affected. If the temperature of the solution be maintained at about 80° C. during the absorption of the chlorine, a smaller quantity of the latter will produce the maximum effect. When a solution of bleaching powder is used the addition of *half* the theoretical quantity produces a marked improvement in the colour obtained. Worst dyed black on chromium mordant with the chlorinised extract and exposed to the light for six weeks does not undergo more change in shade than a sample dyed with ordinary eured wood.

The dyeing power of hæmatoxylin is likewise increased by exposure to chlorine, the greatest development being produced when four atoms of chlorine are supplied for each molecule of hæmatoxylin; this is equivalent to 47 per cent. of the latter. When bleaching powder is employed, the same effect is produced when the proportion of available chlorine to hæmatoxylin is only 23.5 per cent.

Erdmann (J. prakt. Chem. 26, 202), Reim. (Ber. 4, 329), and Dralle (Ber. 17, 372; this Journal, 1884, 242) were unable to isolate hæmatein from the product of the action of chlorine on hæmatoxylin.

By dissolving the hæmatoxylin in hot water, allowing to cool, treating with chlorine water containing the calculated amount of chlorine, and repeatedly washing with ether containing a small quantity of alcohol, the authors obtained on evaporation and drying a brownish resinous mass completely soluble in alcohol. The residue on treatment with chloroform yielded a small quantity of a white crystalline substance soluble also in ether, water and acetic acid. By treating the residue with ether two bodies were separated, one having a brownish, resinous appearance, the other a bright greenish metallic lustre. The former appears to be a chloro-derivative of hæmatein or hæmatoxylin, while the latter possesses physical and chemical properties identical with hæmatein.

Hæmatein is also found in the extract from eured wood, and appears to exist in about the same proportion as in the chlorinised hæmatoxylin, the colours obtained in comparative dye tests being similar in depth and shade. Hæmatein has only a special value in wool dyeing where the bath is neutral or slightly acid; in this case the shade given by hæmatein is at least twice as full as that obtained from hæmatoxylin. In "speck dyeing," however, where the solution is strongly alkaline, the reverse is the case, hæmatein being of little practical value. From this it appears that when alkaline solutions are used in the application of logwood, the extract or decoction should be made of dry eured wood, whilst for wool dyeing much better results follow from the use of eured wood.—S. B. A. A.

*Note on some Hypochlorite Solutions used for Bleaching.*  
Osterberger and Capelle. Bull. Soc. Ind. Ronen, 1889, 375—378.

UNTIL the year 1876, bleaching soda, or "can de Javel," was made by passing chlorine gas into a dilute solution of sodium hydrate or carbonate. Plancau, about this period, succeeded in making a more concentrated solution by adding dry bleaching-powder to caustic soda liquor of 19° B. Since then there has appeared in the market a number of preparations stated to possess remarkable properties. One of the first of them was a liquor which attracted considerable attention under the name of "chlorozone." Its discoverer, Count Brochocki, manufactured it by forcing with an air-blast chlorine, liberated from bleaching-powder by the action of dilute sulphuric acid, into two vessels filled with dilute caustic soda; as the caustic soda in the first vessel became neutralised, the hypochlorite, which had been first formed, was decomposed, hypochlorous acid being liberated; the action in the second vessel was only allowed to proceed as far as the formation of hypochlorite. The contents of the two vessels were mixed forming "chlorozone." According to Brochocki, chlorozone contains oxygenated compounds of chlorine, such as chloric acid and chlorine peroxide. On the other hand, Lunge and Landolt, who have examined the product, find it to be merely a dilute solution of hypochlorous acid in bleaching-soda liquor.

Owing to the commercial success of the original chlorozone, numerous manufacturers have been led to make imitations. Some of them have not scrupled to sell, under the names of chlorozone and chlorogene, ordinary bleaching-soda, which they guaranteed to be free from caustic, but which is of a composition such as is shown by the following example:—

	Grms. per Litre.
Active chlorine .....	115.68
Inactive chlorine .....	29.96
Sodium carbonate .....	17.31
Sodium hydrate .....	19.58

The density of this particular sample was 24° B.—E. B.

*Nigrisine.* T. Baumann. Bull. Soc. Ind. Mulhouse, 1890, 65—68.

NIGRISINE is the commercial name of a basic grey dyestuff recently discovered by E. Ehrmann. It comes into commerce in the form of a black powder, soluble in water and acetic and hydrochloric acids. 1 litre of water at 100° dissolves 80 grms. of the dyestuff; it is rather more soluble in acetic acid of 6° B., but dissolves most easily in a mixture of equal volumes of such acid and water; it is almost insoluble in 90 per cent. alcohol, and but slightly soluble in ethyl-tartaric acid and acetic. Its chief reactions are as follow:—In water it dissolves with a reddish-grey colour, which is changed to a blue-grey by the addition of acid; concentrated sulphuric acid dissolves it with a pure grey colour, which on the gradual addition of water, changes successively to red-grey and blue-grey; nitric acid added to an aqueous solution oxidises the dye, producing a red-brown solution; stannous chloride and hydrochloric acid reduce it, a yellow solution being obtained, which when diluted with water, deposits a brown precipitate, the solution remaining pale yellow; zinc dust and acid reduce the dye, also forming a yellow solution, which, on exposure to the air or by oxidation with ferric chloride, recovers its original tint; potassium bichromate produces a brown precipitate, soluble in acetic or tartaric acid with a grey-blue, in hydrochloric acid with a red-blue colour; a characteristic test consists in adding sodium hydrate to a solution of the dye, and extracting the precipitated base with ether or light petroleum, which are coloured cherry-red. On separating the coloured layer and shaking it up with acetic acid, the latter becomes coloured greenish-blue.

Nigrisine is distinguished by its purity of shade, strong colouring power, fastness, and the variety of compound shades, which, in admixture with other dyestuffs, it is capable of yielding.

The following examples of colour-mixtures will serve to show its mode of application in calico-printing:—

	Dark Grey.	Medium Grey.
	Parts,	Parts,
Nigrisine .....	40	10
Acetic acid of 6° B. ....	200	200
Water .....	200	250
Gum tragacanth paste .....	500	500
Tannic acid .....	80	20
Tartaric acid .....	15	15

Increase of the proportion of tartaric acid renders the shade bluer and more regular, but endangers the strength of the cotton. A mixture made without tannic acid, printed and steamed, yields a rather reddish-grey, which is as fast as when fixed with tannic acid, and its fastness may even be slightly increased by chroming after steaming. Such a mixture, in which the tannic acid is omitted, serves equally well for cotton, wool, and silk, or mixed goods.

Nigrisine does not require a mordant for dyeing bleached cotton. Full shades are obtained with 1 to 3 per cent. of the dye. Cotton mordanted with antimony tannate takes the dye well. A method of dyeing, suitable in this case,

consists in padding the pieces in a solution containing from 2 to 10 grms. of the dye per litre, drying, and steaming, or the pieces may be passed, without drying, through a 0.5 per cent. solution of potassium bichromate at a temperature of about 60°, when an insoluble chromate of the colour-base is formed.

The many advantages of this dye, combined with its low price, should, in the opinion of the author, secure its employment in dyeing and calico-printing.—E. B.

*A Mishap in Cotton Bleaching.* A. Scheurer. Bull. Soc. Ind. Mulhouse, 1820, 78—90.

THE author enumerates some of the causes of bad work experienced on starting a new bleachworks, and then recounts his own experiments made some time ago for the purpose of discovering the cause of a troublesome defect, which frequently appeared in the printed cloth in the works with which he is connected. After the prints had been steamed there were frequently noticeable broad stripes, of 60 to 80 cm. width, extending across the cloth, and occurring regularly at intervals of 7 metres. On these stripes the colours were defective. There was, however, a central portion of 8 to 10 cm. in the stripe where the colours were normal. The defect manifested itself in the following way: the extract reds and pinks bled, forming "auroles"; the extract purple was of a reddish hue. Attention was at first directed to the hanging rails in the steaming machine, the back-greys, and the preparation with oleine, but no fault could be found with any of these. Eventually the cause was traced to the presence of aluminium chloride in the water of the bleach-house washing machine, the distance of 7 metres mentioned above corresponding to the length of cloth lying between two successive "nips" in the same.

The aluminium chloride was formed by the sours draining from a heap of cloth on a stillage, escaping through the sides of an asphalt gutter, through the soil, and thence into a canal from which the wash-water was taken. The mortar in the bricked wall of the canal was dissolved away and aluminium chloride formed. It was found that the defect was produced in the cloth contained in the washing machine during the dinner hour, when the machine was stopped, the cloth out of the water becoming drier, and the mordant fixing on the exposed parts, whilst the portion pressed between the rollers remained moist, and, consequently, unmordanted. It was further found that cotton had the power of attracting and fixing alumina even from a very acid solution of aluminium chloride, and that the alumina contained in rosin and soda can give rise to a light mordanting.—E. B.

#### PATENTS.

*Improvements in Machines for Sizing and Painting Cloth or Fabrics.* A. J. Boulton, London. From D. A. Page, R. C. and M. Bird, Chicago, U.S.A. Eng. Pat. 7185, April 30, 1889. 1s. 1d.

THE improvements claimed relate to mechanism for sizing and painting fabrics, such as window curtains.

The fabric is taken from a roll at one end of the machine, sized, according to its quality, on one or both sides, dried, painted upon both sides, again dried, and finally rolled up at the other end of the machine, all the operations being continuous. Drawings are given in the original specification to illustrate the details of construction and mode of working.—E. B.

*Process for Cleansing and Bleaching Fibrous Substances, and for fixing Organic Colouring Matters thereon by Means of Acid and Alkaline Residues of Naphtha Manufacture or of Specially Prepared Substances analogous thereto.* V. Sehevelin, Balakhna, and P. Mindovsky, Moscow, Russia. Eng. Pat. 8107, May 15, 1889. 8d.

SULPHO castor oil-acid, sulphopyroterebene-acid, sulpho-oleine-acid, and the "soda and acid residues" obtained in the washing of mineral and coal-tar oils, when neutralised

with alkalis, effect the cleansing of textile fibres more energetically than does soap. The fats contained in greasy wool are readily dissolved by the "residue" solution, a more complete removal of the grease being so obtained than with the usual methods of washing. Treatment of the alkaline solutions with sulphur dioxide to acid reaction causes their bleaching action to be increased. Further, it is claimed, fabrics composed of vegetable fibres, after being boiled in the solutions of the substances above mentioned, can be dyed with organic colouring matters, without further mordanting. (See also this Journal 1890, 488.)—E. B.

*Improvements in Apparatus for Dyeing and otherwise Treating Wool.* S. Mason, jun., Manchester. Eng. Pat. 9149, June 3, 1889. 8d.

THIS is an arrangement for dyeing or otherwise treating wool in the form of "tops" in a keir or closed vessel. The apparatus cannot be properly described apart from the drawings given with the original specification.—E. B.

*Improvements in Solutions for Removing Rust Stains from Cloth.* A. Buecher, Heidelberg, Germany. Eng. Pat. 9600, June 11, 1889. 4d.

RUST stains in cloth are removed by treatment with the following mixture:—15 grms. of oxalic acid, 20 grms. of chloride of tin, 1.5 litres of water, and 50 cc. of a 0.5 per cent. solution of benzoic acid.—E. B.

*Improvements in the Method of and Apparatus for Dyeing and similarly Treating Yarns and Textile Materials in all Stages of Preparation.* W. E. Heys, Manchester. From C. Vandermeirsche, Paris, France. Eng. Pat. 9836, June 15, 1889. 8d.

THIS invention relates to a mechanical arrangement (described in detail with the aid of drawings in the original specification) for the purpose of carbonising, washing, scouring, mordanting, and dyeing woollen or other textile material. The material to be treated is placed in pots, which have their upper and lower ends perforated and removable, and which are caused intermittently to rotate in a bath of the liquor corresponding to a particular operation, a stream of the same liquor being injected through the material in the pots during the periods of rest.—E. B.

*An Improved Copying Ink.* W. S. Conrad and H. T. Lilley, Southsea. Eng. Pat. 2011, February 7, 1890. 4d.

By this ink a clear copy of a written document can be rapidly obtained "by simply blotting the writing with any ordinary copying paper," both original and copy being left dry. The ingredients used are a solution of gall nuts in water, sulphate of iron, aniline blue black, chloride of magnesium, and "glycerin-indigo" (prepared by adding one-third of an ounce of indigo-carmin to each pound of glycerol).—E. G. C.

*Improvements in or relating to the Dyeing of Yarn.* A. J. Boulton, London. From A. and M. Koblenzer, Augsburg, Germany. Eng. Pat. 4683, March 25, 1890. 4d.

IN dyeing cotton yarn in the cop, a thorough penetration of the dye is effected by the employment of a mordant such as primuline, applied under a pressure of 2 to 3 atmospheres, the cops being afterwards rinsed in ice-cold water, then treated with an acidulated solution of sodium nitrite, again rinsed, and dyed with "naphthol or naphthylamine" under a pressure of 2 to 3 atmospheres.—E. B.

## VII.—ACIDS, ALKALIS, AND SALTS.

## On the Substitution of Salts in Complex Solutions.

A. Etard. *Compt. Rend.* **110**, 186—188.

I. The author has previously investigated, by a special method, the complete curves of solubility for a mixture of potassium and sodium chloride made under the special conditions enumerated below (III.) (this Journal, 1890, 290), and has thus determined the variation with temperature in the proportion of two metals present, which share the same metalloïd. He now investigates the problem when the metal of the two dissolved salts is the same and the metalloïd different.

II. The solubility  $S$  (defined as the percentage of salt in a saturated solution) of potassium iodide may be represented as a function of the temperature,  $t$ , by three straight lines, extending the first from  $-22^\circ$  to  $0^\circ$  (insufficiently determined to be represented by a formula), the second from  $0^\circ$  to  $108^\circ$  (angular coefficient =  $0.1257 t$ ), the third (No. 1 on diagram), from  $108^\circ$  to  $220^\circ$  (angular coefficient =  $0.0603$ ). If this last segment be produced by extrapolation, its "limiting point" is found to occur at  $637^\circ$ ; the melting point of potassium iodide being 639, according to Carnelley. (The "limiting point" has been defined in a previous paper as the theoretical temperature at which, supposing that its strength continue to increase at a constant rate with rise of temperature the solution would contain the limiting amount of salt, i.e., 100 per cent.)

From the examination of a large number of complete curves of solubility it appears that they are composed of segments of straight lines, the angles which these lines make with the temperature axis successively decreasing with increase of temperature. Most perturbations take place below  $130^\circ$ , a temperature at which in all likelihood hydrates no longer exist. And it seems probable that the lines least inclined to the temperature axis, which have been determined

in many cases experimentally as far as  $260^\circ$ , represent the phenomenon of solution much beyond this temperature. Chemical decompositions, the occurrence of the critical point of solvents, &c., however, would prevent the lines representing the facts as far as the "limiting point." But they bear a real relation to this "limiting point," which, in many cases, coincides with the melting point of the salt, and hence possesses a precise physical signification.

III. If a small quantity of water be added to an excess of potassium iodide and potassium bromide, the two salts being mixed in any proportion, it is found:—

- (1.) That the total weight of salt dissolved is the same at all temperatures as if potassium iodide alone had been used; the line (1) represents solubility both of potassium iodide alone and of the mixture of potassium iodide and potassium bromide. Hence the "limiting point" for  $KI + KBr$  solution is 639, the melting point of  $KI$ .
- (2.) From the analysis of the solutions it follows that in the mixture the potassium bromide follows the law of solubility of potassium iodide and not its own. It is as if bromine were substituted for iodide.
- (3.) It may be calculated by extrapolation that at the limiting point the salt would consist approximately of two-thirds (66.4 per cent.) of potassium iodide and one-third (33.6 per cent.) of potassium bromide; that is to say, if the experimental lines (3) and (4) be considered separately, and produced to their limiting points, the ordinates at these points correspond to the figures given above, which, as will be seen, add up to 100.

IV. The line for a mixture of potassium iodide and potassium chloride (5) coincides in the same way with the line for potassium iodide. At the limiting temperature the salt would consist of four-fifths of iodide and one-fifth of chloride (see curves (7) and (8)). The couple, potassium bromide and potassium chloride, gave similar results, the

SOLUBILITY OF A MIXTURE OF (KI + KBr).

SOLUBILITY OF MIXTURES OF (KI + KCl).

limiting composition being calculated to be three-quarters bromide and a quarter chloride. The research is in progress. —P. J. H.

The Preparation of Alkaline Nitrites. G. A. Le Roy. *Bull. Soc. Ind. Rouen*, 1889, 363—370.

THE author enumerates the various processes known for the preparation of nitrites.

1. *Decomposition of Nitrates.*—This is the oldest method, and consists in heating a nitrate till a portion of its oxygen has been evolved as in the equation:  $\text{NaNO}_3 = \text{NaNO}_2 + \text{O}$ . If the heating be continued complete decomposition ensues, more oxygen, together with nitrous gases, being evolved. This method is not employed for manufacturing purposes on account of the difficulty of controlling the reaction and the poor yield obtained.

2. *From Lead Nitrate*.—Basic lead nitrite is first prepared by boiling a solution of one part of lead nitrate with one or two parts of lead in thin sheets, the following reaction taking place:—

The excess of lead oxide is precipitated by a current of carbon dioxide, and the solution of normal lead nitrite so obtained is decomposed with an alkaline carbonate—

3. *Method with Nitrogen Dioxide*.—Gay-Lussac stated that pure alkaline nitrite was formed by absorbing a mixture of four volumes of nitrogen dioxide and one of oxygen in a concentrated solution of alkali. Berthelot has since shown that when the nitrous acid formed is absorbed as it is produced, the relative proportions of the two gases are immaterial, but that, otherwise, nitrogen tetroxide is produced, and then, on absorption, a mixture of nitrate and nitrite is obtained, thus—

4. *Method with Nitrous Acid*.—Nitrous acid, obtained by acting on arsenious oxide, starch, &c., with nitric acid, is passed into a solution of alkali. To obtain the gas nearly free from nitrogen tetroxide, Lunge recommends the employment of one part of arsenious oxide or starch to every 10 parts of nitric acid of sp. gr. 1.30 to 1.35.

5. *Method with Barium Dioxide*.—This method, due to H. Debray, consists in passing nitrous oxide over gently-heated barium dioxide, the gas being absorbed with the formation of barium nitrite:  $2 \text{ NO} + \text{BaO}_2 = \text{Ba(NO}_2)_2$ . The product is treated with water, filtered, any barium hydrate present removed by carbon dioxide, and the solution decomposed with a sulphate—

The author of this process incidentally remarks that lead dioxide cannot be used instead of barium dioxide in this process.

6. *Method with Copper*.—Persoz has proposed to partially deoxidise alkaline nitrates with finely-divided copper—

The copper for the purpose is obtained by igniting cupric acetate in closed vessels. Metallic copper may be regenerated from the oxide by a current of hydrogen. Müller and Pauly obtain the copper in the necessary fine state of division by reducing a solution of copper sulphate with zinc.

7. *Method with Lead*.—Hampe or, according to H. Rose and Fresenius, Stromeyer has the credit of originating this process. It consists in fusing a mixture of a nitrate and metallic lead, the following equation representing the reaction which takes place:  $\text{NaNO}_3 + \text{Pb} = \text{NaNO}_2 + \text{PbO}$ . The mass is dissolved out with water and treated with carbon dioxide and hydrogen sulphide or ammonium sulphide to eliminate lead; the solution is then filtered, evaporated to dryness, the residue heated to destroy hyposulphites, again dissolved in water, and crystallised.

8. *Method with Litharge*.—Burton, in his process, commences with lead oxide, and makes use of the deoxidising powers of the same in becoming converted into lead tetroxide:  $\text{NaNO}_3 + 3 \text{ PbO} = \text{NaNO}_2 + \text{Pb}_3\text{O}_4$ .

A mixture, in proper proportions, of lead nitrate, sodium carbonate and litharge, is heated, and the sodium sulphate and nitrite formed are dissolved in water and separated by crystallisation.

9. *Method with Carbon*.—This method, known since 1828, is of no industrial value, as it is impossible to avoid the simultaneous production of alkaline carbonate. Finely powdered charcoal, starch, or, best of all, graphite, is heated with the nitrate  $\text{NaNO}_3 + \text{C} = \text{NaNO}_2 + \text{CO}$ .

10. *Method with Alkaline Sulphites*.—Etard suggested the heating together of molecular equivalents of a nitrate and sulphite of the same base, sulphate and nitrate being formed thus:  $\text{NaNO}_3 + \text{Na}_2\text{SO}_3 = \text{NaNO}_2 + \text{Na}_2\text{SO}_4$ .

The two salts are separated by crystallisation.

11. *Method with Zinc*.—Stahl-schmidt has described a wet method, in which, in an ammoniacal solution, the nitrate is reduced to nitrite by zinc dust, the temperature being kept below 50°. When the reaction is complete, the solution is boiled to expel ammonia, treated with carbon dioxide to precipitate zinc, nitric acid added to decompose the alkaline carbonate present, and the nitrite crystallised out.

12. *Method with Manganese and Chromium Oxides*.—C. Huggenberg, in 1887, patented the following method: manganese oxide, chromium oxide, or arsenious oxide, is fused with a nitrate and an alkali or alkaline earth; an example of the reaction is shown in the equation—

13. *Miscellaneous Methods*.—Such are the reduction of the fused nitrate by a current of hydrogen, the saponification of alkyl nitrates, and the reduction of alkaline nitrates by microbes, a curious fact discovered by Gayon and Dupetit.

14. *Method with Barium Sulphide*.—This method has been proposed by the author. It has the advantage of yielding a nitrite free from impurities requiring special modes of separation. The alkaline nitrate is heated with barium sulphide in the proportions required in the equation:  $4 \text{ NaNO}_3 + \text{BaS} = 4 \text{ NaNO}_2 + \text{BaSO}_4$ .

It is necessary to employ barium sulphide free from carbon. When the mineral contains barium sulphate it is rather an advantage than otherwise, as it serves to moderate the reaction. The barium sulphate produced can be easily reconverted into sulphide (this Journal, 1889, 933).

—E. B.

#### *Manufacture of Ammonium Chloride from By-Products in Gas Manufacture and Metallic Chlorides.* Dubose and Heuzey. Bull. Soc. Ind. Rouen, 1889, 438—442.

IN the manufacture of gas from coal, ammoniacal liquors are produced which yield three commercial products.

1st, the crude liquor; density 4° to 5° B. containing about 4 per cent. of  $\text{NH}_3$ .

2nd, the concentrated liquor; density 10° to 12° B., containing 12—14 per cent. of  $\text{NH}_3$ .

3rd, crystallised ammonium sulphate containing 20 per cent. to 21 per cent. of nitrogen, corresponding to 25 per cent. of  $\text{NH}_3$ .

These three products may be treated with metallic chlorides so as to yield ammonium chloride, the process varying with the product treated.

(1.) *Treatment of the Crude and Concentrated Ammoniacal Liquors*.—These liquors contain besides ammonium sulphate, free ammonia, ammonium chloride and cyanide, a considerable amount of ammonium carbonate and sulphide which precludes the possibility of conversion into chloride by the direct action of hydrochloric acid, which would give rise to large volumes of carbon dioxide and sulphuretted hydrogen. The authors base their new process on the precipitation of the sulphur and carbonic acid by double decomposition with a mixture of the chlorides of iron and calcium in proper proportions; neither the sulphides nor carbonates of these metals being soluble in presence of ammonium chloride. The originality of the method consists in using the mixture of iron and calcium chlorides; it has the advantage of (1) complete desulphurisation, which is not possible with the use of calcium chloride alone, owing to the slowness with which calcium sulphide is formed; and (2) rapid precipitation of the carbonates as  $\text{CaCO}_3$ , which does not take place in the presence of iron alone, as the colloidal carbonate of iron is then formed.

The process is carried out as follows:—The gas liquors are freed from tar by being left for 48 hours in cisterns, and are then pumped up into a tank, into the bottom of which the necessary quantity of the mixed chlorides has been already introduced. The mixture is stirred mechanically and left to settle for 12 hours. The upper two-thirds of the mother-liquor are then perfectly clear, and absolutely free from sulphide and carbonate. After being slightly acidified, if necessary, this portion is conveyed directly by pipes to the concentrating pans. The precipitate, consisting

of the mixed carbonates and sulphides of iron and calcium, is filtered on horizontal filters or, preferably, in the filter-press. The dried residue forms an excellent purifying mixture for coal-gas, analogous to Laming's mixture.

The density of the liquors thus obtained is generally  $7^{\circ}$  B., and they must be evaporated down to  $13^{\circ}$  B. For this purpose the authors use flat iron pans made of strong sheet or cast iron, containing 2,000 litres. A close grained cast-iron wears best. The fire and pans are covered in entirely by a hood of silicated and stuccoed wood. All the joints are made tight so that the vapours may be entirely carried off by a large flue into the main chimney shaft, where any sulphuretted hydrogen, due to possible imperfect desulphurisation, is burnt by a special arrangement. When the density reaches  $13^{\circ}$  B. the liquid is drawn off and left to crystallise in wooden troughs. It takes 15 days to crystallise completely, the crust being broken each day. When acicular crystals of the ammonium chloride are to be produced, the operation is carried out exactly as above. If cubes be desired, 5 per cent. of a solution of perchloride of iron (density  $35^{\circ}$  B.) must be added to the mother-liquors; this seems to act merely "by presence" and remains in the mother-liquors. For certain chlorides used in galvanising, manganese salts or zinc salts, or fatty matters are added. When the crystallisation is complete the residual liquid is drawn off and pumped back into the evaporating pans, and the crystals are taken out, drained, and then either sent to a drying chamber whose temperature is  $50^{\circ}$ — $60^{\circ}$ , or fritted in a reverberatory oven. Slaked lime is used to give the brownish-yellow colour required in commerce, and the product is then packed in barrels.

To produce the refined salt, the solution is only concentrated to  $11^{\circ}$  B., then pumped into wooden troughs, and the metals it contains precipitated with ammonium sulphide. The liquid is then concentrated in vessels made of enamelled cast iron, and crystallised in earthenware pans; the crystals are drained and dried in the drying chamber. As the enamel frequently splits off the cast-iron pans, it must be replaced by a cement composed of dried calcium carbonate and potassium silicate, made insoluble by the action of hydrofluosilicic acid.

(2.) *Treatment of Ammonium Sulphate by Metallic Chlorides.*—The treatment varies with the nature of the chloride added.

1st. When the metallic chloride used yields an insoluble sulphate (e.g. Ca) on addition to the solution of ammonium sulphate:—

The ammonium sulphate is dissolved in the smallest quantity of water possible; it is then pumped up into a trough placed at a certain height, into which the necessary amount of chloride has been previously introduced. The mixture is stirred constantly, and when the reaction is complete, it is sent to a special filtering apparatus, or to a filter-press in which thorough washing is possible. The filtered liquid is then concentrated in the manner previously described. The residue of calcium sulphate may be used for agricultural purposes.

2nd. When the metallic chloride ( $\text{NaCl}$ ,  $\text{FeCl}_2$ ,  $\text{ZnCl}_2$ ,  $\text{MnCl}_2$ ) yields a soluble sulphate:—

Any of the chlorides mentioned might be used, but the one actually employed is ferrous chloride. A solution of the crude salt (such as is produced in cleaning iron surfaces) of a density  $24^{\circ}$  B. and containing 25 per cent. of substance, is neutralised and pumped into cauldrons, where it is heated to over  $60^{\circ}$  C., and then the necessary amount of ammonium sulphate is added. Double decomposition ensues, and as soon as the surface begins to froth the mother-liquor is sent to the crystallising vessels where 95 per cent. of the iron sulphate crystallises out. The iron crystals are washed and the wash-water added to the ammonium chloride mother-liquors. To obtain the crude ammonium chloride these liquors are simply evaporated in flat pans; to obtain a refined salt, ammonium sulphide and barium chloride are added, and after filtration the liquors are concentrated in enamelled vessels as before.—P. J. H.

*On the Constitution of Manganese Peroxide.* W. Spring and M. Lucien. *Bull. Soc. Chim.* 1890, **3**, 4—8.

THE authors begin their paper by enumerating the theories which have been proposed to account for the behaviour of the various peroxides. Traube (*Ber.* **21**, 821) considers them as containing oxygen in the molecular state,  $\text{O} = \text{O}$ . Richarz has opposed these views (*Ber.* **21**, 1675), and returns to the old theory of Schönbein on ozonides and antozonides, for which the formulae would be—

The formula for manganese dioxide would, according to Richarz, be  $\text{O} = \text{Mn} = \text{O}$ ; and would thus agree with Frankes' proposal (*J. prakt. Chem.* **36**, 451) to denote by a formula—

the hydrated dioxide formed by the action of water on the sulphate  $\text{O} = \text{MnSO}_4$ , which is itself produced in the decomposition of  $\text{Mn}_2(\text{SO}_4)_3$  (Fremy, *Compt. Rend.* **82**, 475).

It has, however, often been proposed to regard  $\text{MnO}_2$ , not as a peroxide, but rather as a manganate or permanganate of manganese either  $\text{MnO}$ ,  $\text{MnO}_3 (= 2 \text{ MnO}_2)$ , or  $3 \text{ MnO}$ ,  $\text{Mn}_2\text{O}_7 (= 5 \text{ MnO}_2)$ .

(See Guyard, *Bull. Soc. Chim.* [2], **1**, 88; and Volhard, *Annalen*, **198**, 318.)

Objections have to these views been raised by O. T. Christensen (this *Journal*, 1883, 346), but the authors think that the latter formula accounts best for the formation of manganese peroxide by the action of potassium permanganate on manganous salts,—

1.

2.

The saline and sometimes basic properties of manganese peroxide are better expressed by the formula  $3 \text{ MnO}, \text{Mn}_2\text{O}_7$ , which also brings out the relation of this body to the more basic compound  $4 \text{ MnO}, \text{Mn}_2\text{O}_7$ . (See Gorgeu, *Ann. Chim. et phys.* [3], **66**, 160; and Weldon, *Chem. News* **20**, 109 (1869), and *Monit. Scient.* 1874, **4**, 891).

In order to elucidate the question, the authors have made the following experiments:—

1st. Barium dioxide was ground with crystallised manganous chloride in slight excess. A reaction immediately set in and oxygen was evolved. A black mass was produced which after being freed from the barium chloride produced and the excess of manganous chloride, proved to be  $\text{Mn}_2\text{O}_7$ . Hence it follows that manganese dioxide has a constitution unlike that of  $\text{BaO}_2$ .\*

2nd. Pure barium manganate was treated with manganous sulphate. Double decomposition takes place, but only slowly; after heating for a week on the water-bath, 10 grms. of a substance were obtained, which corresponded to the formula  $\text{Mn}_2\text{O}_7$ , and which may in this case be represented as manganous manganate,  $\text{MnO}, \text{MnO}_3$ . The colour of the body obtained differs slightly from that of ordinary manganous dioxide, but no sufficient evidence was obtained to show that it is really an isomeric substance.

3rd. Sodium manganate was treated with manganous carbonate, but double decomposition did not take place in the same way as in the preceding experiment. The reaction only sets in at a high temperature, and  $\text{Mn}_2\text{O}_7$  is obtained instead of  $\text{Mn}_2\text{O}_3$ . Probably  $\text{Mn}_2\text{O}_3$  is first formed, and this reacts with  $\text{MnO}$  formed by the decomposition of  $\text{MnCO}_3$  by heat ( $\text{MnO}_2 + 2 \text{ MnO} = \text{Mn}_2\text{O}_7$ ).

\* Lead nitrate and silver nitrate react on barium dioxide in the dry state, but in neither case is a peroxide produced:—

The authors are led to this explanation from the fact that no oxygen was evolved during the reaction.

4th. Manganese peroxide was heated with soda in an atmosphere of nitrogen, in order to verify the hypothesis that it is a salt. After washing and drying the products of the reaction, also in an atmosphere of nitrogen, a residue consisting of  $Mn_2O_3$  was found. The authors think this proves that  $MnO$  was formed at some stage of the reaction, and  $Mn_2O_3$  then produced according to the equation  $MnO + MnO_2 = Mn_2O_3$ .

Fremy obtained a residue of  $MnO_2$  from this operation: but he performed it in air, not in nitrogen.

5th. Pure  $Mn_2O_3$  was heated with dilute nitric acid, and it was found that manganese dioxide is formed, not by reduction of the nitric acid, but simultaneously with manganous nitrate,  $Mn_2O_3 + 2 HNO_3 = MnO_2 + Mn(NO_3)_2 + H_2O$ .

The authors conclude that manganese peroxide must be regarded either as  $MnO$ ,  $MnO_3$ , or else as  $3 MnO$ ,  $Mn_2O_7$ .

Possibly the body exists under isomeric states. The authors intend to continue their investigation.—P. J. II.

*On the Native Oxides of Manganese. First Part. The Psilomelanes and Wads.* A. Gorgeu. Bull. Soc. Chim. 1890, 3, 248—255.

Compare this Journal, 1890, 508.

*On the Technical Value and Preparation of Magnesia.* Ann. für Gewerbe und Bauwesen, 35, 1889, 139; and Proc. Inst. Civil Eng. 1890, 53.

MAGNESIA, formerly chiefly valued on account of its medicinal properties, has recently risen into great commercial importance owing to its infusibility and its employment as a lining for converters used in the basic process of steel manufacture. Caron, whose process was in the first instance followed, used calcined magnesite. This was made up with one-sixth of its weight of tender-burned magnesia, and from 10 to 15 per cent. of water, into a plastic state; it was then compressed into bricks in iron moulds, and burned at a dull red heat. Ehrenworth has pointed out that, if the refractory properties of the magnesia are to be evoked to the full, it is of the utmost importance that the whole of the magnesia should be dead-burned; the process, moreover, being carried so far as not only to expel the whole of the carbonic acid, but also to cause the full amount of shrinkage which this material is capable of attaining. This extreme amount of calcination is very difficult to effect, owing to the tendency of the magnesite to fly into splinters, and to drop to pieces when subsequently touched, and in consequence of its being such a bad conductor of heat the stone is very hard to burn in large pieces.

Recently dolomite, which is a double carbonate of lime and magnesia, has been used instead of magnesite. In order to utilise this material there are two processes before the public, that of Closson and that of Scheibler. Under the former plan, the calcined dolomite is mixed with chloride of magnesium, the chlorine in which separates from the magnesia and combines with the lime, yielding a soluble calcium chloride which can readily be washed out, leaving behind the insoluble magnesia. Under the process of Scheibler the calcined dolomite is treated with dissolved sugar, leading to the formation of sugar of lime, and leaving the magnesia. The solution of sugar of lime is then exposed to carbonic acid gas, which separates the lime as a carbonate, leaving the sugar ready for re-use. Both these systems of producing magnesia have the advantage of relative cheapness in their favour, owing to the low price of dolomite. Professor Frank, of Charlottenburg, has advocated the use of magnesia as a substitute for plaster of Paris for casts, and Grundmann has recently shown the advantage of employing a mixture of magnesia and powdered marble for this purpose. The author states that he has found, following the directions given by Hirzel, that a mixture of benzene

and magnesia is the very best possible substance for the removal of grease from drawings, or from any other material.

*Pick's System of Manufacturing Salt in Vacuo.* Perry F. Nursery. Iron, 35, 1890, 488—489.

In the process in ordinary use wrought-iron evaporating pans, which have an area of from 600 to 1,000 superficial feet, are employed. Their usual form is oblong, and their depth ranges from 12 to 16 in. There are three or more fires under each pan, and there is usually a separate pan-house to each pan.

The disadvantages of the ordinary system of salt-making are numerous as well as serious. In the first place, although the salt is raked out regularly, it is found impossible to keep the bottom plates of the pans quite free from it. This deposit, together with the salts of lime and magnesia present in the brine, however carefully the operations be conducted, forms a scale upon the plates which causes them to rapidly burn away and buckle or bend. Repairs are consequently constantly going on in salt works, and indeed this item of maintenance is one of the most serious in a salt manufactory. The finer the salt produced, the heavier are the repairs, and the more frequently the pans require cleaning, the scale having to be frequently chipped by chisels from the plates and damaged plates to be replaced by new ones. These pans cover a large area, and they can never be kept tight. And it does not take long to disable them either, as may be imagined when it is stated that with the most careful working, and the best occasional patching, the life of a brine-pan cannot be put at more than about three years.

Besides repairs to the pans, there is the heavy fuel bill. In order to maintain the brine at the boiling point, and to secure the proper rate of precipitation of the salt according to the quality required, a large consumption of fuel is necessary. Another evil is the production of noxious gases, the effects of which are readily recognisable in the vicinity of salt works. As soon as scale begins to form in the pans the buckling action commences, the rivet seams open, and the brine leaks from the pans into the fire-holes, producing gases which are alike deleterious to animal and vegetable life. The ordinary process of salt making is thus slow and costly, and the output is comparatively small in proportion to the area occupied by the works and the quantity of fuel consumed.

Dr. Pick in his process introduces principles similar to those upon which the Rillieux or triple effect system depends, which system is, as is well known, in use for the evaporation of liquids in certain other manufactures, and he engrafs upon the Rillieux apparatus, the vacuum filter, which contributes much to the success of the method. As will be seen from the illustration, Dr. Pick's apparatus consists of three separate but similar sections, each section consisting of four main and closely connected parts. These are the boiling chamber A, the heating chamber B, the collecting chamber C, and the filtering chamber D. The three sections are placed side by side a few feet apart, and they are connected together by pipes as shown. The heating chamber B of the first section is placed in communication with a steam boiler, or with the exhaust steam from an engine, by means of the pipe E. The boiling chamber A of the first section is placed in communication with the heating chamber B of the second section by means of the pipe F, the boiling chamber A of the second section communicating in its turn with the heating chamber B of the third section by the pipe G. This latter section has its boiling chamber placed in communication with a jet condenser and air pump as shown. G is the brine inlet pipe to the various sections which is in communication with the brine tanks, the brine being raised by vacuum and supplied automatically to the several sections. H is a pipe for automatically conducting the brine from the filtering chambers D, D', and D'', to the boiling chamber of each section, under the special conditions which will be hereafter explained. J is a small pipe which connects the boiling chamber of the first and second sections with the condenser, and is used for assisting in maintaining a vacuum in each of those chambers. In like manner K is a small pipe for assisting the vacuum in the heating chambers of the second and third sections by clearing them of surplus air.

PICK'S APPARATUS FOR THE MANUFACTURE OF SALT IN VACUO.

The boiling chamber of each section is simply a cast-iron cylinder, of larger diameter than the heating chamber beneath it. The object of the increased diameter is to enable the chamber to contain a large quantity of brine with a minimum of depth and a maximum of evaporating surface. The usual level of the brine is seen in the first section, which in fact is a sectional view of a single apparatus, the second and third sections being shown in elevation. The heating chamber consists of a series of conical tubes of comparatively small diameter surrounding a central tube of larger diameter. The whole of the tubes are inserted in a tube plate at top and bottom, and enclosed in a cylindrical chamber, into which steam is admitted in the first section by the pipe E, and after imparting its heat to the brine it is condensed, and passes away to a steam trap as shown. In the second and third sections, the condensed water is drawn off by pumps. The reason for having the tubes conical is to prevent sealing, or, should sealing take place, that it may be easily removed, the larger diameter of the tubes being at the bottom. The author's experience of the working of the system, however, leads him to believe that sealing will not take place, so moderate is the heat applied, so rapid the circulation of the brine, and so powerful the ebullition maintained. It is to promote and increase the rapidity of the circulation that the central enlarged tube is employed. In operation, the brine heated by the small tubes passes upwards through them to the boiling chamber. It then makes for the centre, and returns downwards through the large central tube by reason of the lower temperature prevailing within that tube. The proportion of the volume of brine to the heating surface being much greater in the large tube than in the smaller tubes causes a reduced temperature within it, and the rapidity of the circulation is thereby increased in accordance with the natural law that heated fluids or gases ascend, while those of a lower temperature descend.

The settling chamber, immediately beneath the heating chamber, serves for collecting the salt as it is precipitated. It settles readily, as no movement takes place in the brine at that point. It is, of course, in direct communication with the upper or boiling chamber through the tubes of the heating chamber. This collecting chamber terminates in a sluice valve, and is in this way connected with the vacuum filter beneath it, which forms an important and essential feature of Pick's system. Each filter consists of an upper fixed portion and a lower hinged portion, the filtering medium being attached to the lower portion of the filter at its junction with the upper part. The upper part is fitted with an air inlet cock and a water pipe, ending in a rose for washing the salt if necessary. The lower part of the filter is connected with the boiling chamber by a tube, the lower portion of which, as far up as the valve, is flexible, and yields when the filter is open, as will be seen from the dotted lines.

The method of operating Pick's system is briefly as follows:—Each of the three sections having been charged

with brine to the proper level, which is that indicated in the boiling chamber A, steam is admitted to the heating chamber of the first section, in which the highest temperature is maintained. The brine in that section becomes quickly heated, and the steam given off from that brine enters the heating chamber of the second section, heating the brine in that section. The steam given off from the brine in the first section, after doing its work in the heating chamber of the second section, condenses and produces a vacuum in the boiling chamber of the first section, which vacuum is aided, if necessary, by opening the valve on the connexion with the vacuum pump. The pressure being reduced, the brine in the first chamber enters into violent ebullition at a comparatively low temperature. The same process is repeated in the second section, the steam chamber of the third section acting as a condenser, and producing a vacuum in the boiling chamber of the second section. The steam generated in the third section is drawn off by the vacuum pump, and condensed by the jet condenser as shown. It will be seen that the highest vacuum and the lowest temperature exist in the third section, while the highest temperature and the lowest vacuum occur in the first section. As the salt is precipitated it settles in the collecting chamber, and at stated intervals the sluice valve is opened and the salt and brine are admitted into the filtering chamber. After settling there for a few seconds, the sluice valve is closed and the air cock on the filter is opened. The valve on the ascension pipe H is then opened, and in a few seconds more the whole of the brine, in which the salt lies as in a bath, is automatically transferred to the vacuum chamber, leaving the charge of salt resting on the filtering medium and perfectly free from brine. The valve on the ascension pipe is then closed, the filter opened, and the charge withdrawn. The filter is then closed ready for another charge of salt.

It is stated that during the operation of letting down the charge of salt and withdrawing it from the vacuum filter, it is not necessary to stop working, the processes of evaporation and production being thus rendered simultaneous and continuous, and thus automatic.

The finest salt has been and is still being made equally well in one section, as in three sections, although of course not nearly so economically as if the complete set of three were adopted.

*Twenty-sixth Annual Report on Alkali, &c. Works by the Chief Inspector. Proceedings during the Year 1889. Price 8½d.*

THE report, which deals separately with Scotland (this part will be considered in its proper place), fills 98 pages.

The number of works under inspection was 903, of which 116 were alkali, and 787 works carrying on other processes. There is thus a diminution of three under the former heading and of 20 under the latter. The works were distributed as follows amongst the different districts:—

NUMBER OF REGISTERED WORKS.

	Dist. I. Ireland.	Dist. II. North of England.	Dist. III. Cheshire, N. Wales, and part of Lan- cashire.	Sub-Dist. Widnes.	Dist. IV. East Lan- cashire and York- shire.	Dist. V. South Mid- land.	Dist. VI. South- West of England and South Wales.	Dist. VII. South- Eastern Counties.	Sub-Dist. VIII. Eastern Counties.	Total.		
										1889.	1888.	1887.
Alkali works.....	2	18	15	18	34	10	8	1	10	116	119	116
Other works .....	47	87	75	13	131	124	125	87	98	787	807	811
Total .....	49	105	90	31	165	134	133	88	108	903	926	927

The above table, however, only gives the actual number of works; but inasmuch as many processes are sometimes carried on in one works, the total number of processes

under inspection is much greater than that of the works, as will be seen from the following table, which also gives the distribution of the processes in the different districts:—

TABLE OF SEPARATE PROCESSES UNDER INSPECTION.

	Dist. I. Ireland.	Dist. II. North of England.	Dist. III. Cheshire, N. Wales, and part of Lan- cashire.	Sub-Dist. Widnes.	Dist. IV. East Lan- cashire and York- shire.	Dist. V. South Mid- land.	Dist. VI. South- West of England and South Wales.	Dist. VII. South- Eastern Counties.	Sub-Dist. VII. Eastern Counties.	Total.

During the whole of the year 1889 there were 4,921 visits paid, and 4,808 tests made, by the different inspectors. In the Widnes sub-district alone there were 1,225 of the latter

taken and 737 visits made. A statement of the average escape of acid for the different districts is then subjoined, and is as follows:—

TABLE OF AVERAGE AMOUNT OF ACID GASES ESCAPING FOR EACH DISTRICT.

	Dist. I. Ireland.	Dist. II. North of England.	Dist. III. Cheshire, N. Wales, and part of Lan- cashire.	Sub-Dist. Widnes.	Dist. IV. East Lan- cashire and York- shire.	Dist. V. South Mid- land.	Dist. Acidity of chimneys given as SO <sub>3</sub> . Grains per cubic foot..	0.985	0.63	0.69	0.65	0.51	0.47	0.91	..	0.89	0.715	0.737	0.740
Acidity of gases from manure works given as SO <sub>3</sub> . Grains per cubic foot.....	0.25	0.115	0.48	0.69	0.20	0.47	0.28	..	0.311	0.349	0.250	0.440

\* This figure was given in error in last year's report as 1.32.

It will be noticed that the escape of hydrochloric acid is less than half of that allowed under the Act, whilst the ratio between that which is produced and that which escapes is only as 100 : 1.94 instead of as 100 : 5.00 as allowed by the Act. Though in many cases there were escapes exceeding the legal limits, yet these were almost all assignable to disturbing causes, and were rapidly got under, there being but one prosecution throughout the whole year. This was of a firm in West Ham for failing to adopt the best means for preventing the escape of sulphuretted hydrogen gas in the manufacture of sulphate of ammonia. A fine of 10*l*. and costs was imposed. In the manufacture of salt there

has been, as compared with 1888, a falling off of about 12 per cent., the amount raised in the year 1889 being obtained from the following areas:—

	Tons.
Cheshire .....	1,154,649
Worcestershire .....	221,322
Staffordshire .....	6,500
Derham .....	392,300
Ireland .....	10,600
Scotland .....	7,419
Total in 1889 .....	1,792,790

There has been, as will be noticed, a large increase, about 50 per cent., in the output from Durham. The amount of the soda compounds manufactured is steadily on the increase from year to year, and of this the proportion which is produced by the ammonia-soda process is rising continuously. A comparison between the two rival processes in their consumption of salt brings the following results to light:—

	1889.	1888.	1887.
	Tons.	Tons.	Tons.
Leblanc process .....	584,293	585,498	577,381
Ammonia-soda process .....	219,279	212,181	158,636
Total .....	803,482	797,679	736,017

Besides the salt used in the actual manufacture of alkali, some 56,500 tons are employed in the well-known wet process, as it is termed, for extracting copper from burnt pyrites, bringing up the total consumption of salt to 640,703 tons.

In the production of sulphate of ammonia there has also been a continuous increase during the last few years. The amounts obtained from various sources are here given:—

#### AMOUNT OF SULPHATE OF AMMONIA PRODUCED IN THE UNITED KINGDOM.

	1889.	1888.	1887.
	Tons.	Tons.	Tons.
Gas works .....	100,711	92,896	85,022

Coke and carbonising works.	2,735	2,537	2,678
Total .....	133,604	122,785	113,896

The value of the sulphate of ammonia is thus about a million and a half if the price of the bulk be taken as being about 12*l.* per ton. But even this output, large as it is, is not one-tenth of the amount which might be obtained if all the ammonia evolved from coke ovens, iron works, &c., was saved. Very much of the sulphate of ammonia made here is exported to Germany to be employed in the cultivation of beetroot.

In the manufacture of the sulphate a considerable quantity of sulphuretted hydrogen gas is given off; this is either burnt or passed through ordinary absorbers holding oxide of iron, the latter being much the better plan. In this case the so-called continuous process of manufacture is better employed, as the strain put upon the absorbers at any given time, especially at the commencement of any operation, is not then so excessive. In the case of sulphuretted hydrogen gas it is understood that the whole of it must be absorbed, and that none is to be allowed to escape into the atmosphere.

In the number of works using the Leblanc process there is a further diminution in spite of the aid which the Chance-Claus sulphur recovery process is affording, though possibly in some of the works it came too late to be of service. There are no less than 12 installations of the Chance process now at work, and as many more are in the hands of the builders. The amount of sulphur now being recovered is about 400 tons per month, and this amount will shortly become about 1,000 tons weekly, or some 45,000 tons per annum. By this amount, therefore, will the output from the Sicilian sulphur mines be probably reduced. The total quantity exported from Sicily annually is about 360,000 tons, of which England takes 37,000 tons, and America half of the remainder.

As in the Chance process, the sulphur is recovered in the form of sulphuretted hydrogen; the volumes of gas to be manipulated are enormous. Thus, in one works alone some four million cubic feet of sulphuretted hydrogen are being produced weekly, and it is estimated that when the amount of sulphur recovered reaches 60,000 tons per annum, the quantity of sulphuretted hydrogen to be dealt with will touch 1,508 million cubic feet annually. Great difficulty is experienced in removing the last traces of the gas, much of it after passing through the Claus kiln existing and escaping as sulphurous acid gas. To produce as little of this latter gas as possible it has been found to be advantageous to keep the former in slight excess over the air admitted for the partial combustion of the gas and to keep the temperature of the kiln low.

In the different works much more efficient apparatus and appliances are being introduced. Thus, in the manufacture of mineral phosphate the mixing is conducted in a closed vessel provided with a stirrer driven from the outside, and the mixture is then sent into a closed chamber or "den" where it remains until the discharge of acid vapour has ceased, the gases evolved being passed through wash towers. After such washing there should not be more residual acid gas than is equivalent to 0.2 grains of sulphuric anhydride ( $\text{SO}_3$ ) per cubic foot. In the case of fetid gases the use of a cremator or combustion chamber for their decomposition has been recommended. This plan has been adopted by the Manchester Corporation for destroying the noxious gases given off in the boiling down of the liquid obtained by them in their pail system of removing house sewage.

With regard to the question of the evolution of black smoke, a committee has been formed in Manchester for the purpose of testing smoke appliances. It will pay attention to such points amongst others as (1) practical freedom from smoke; (2) reasonable amount of duty; (3) economy of fuel, &c. Experiments on and tests of the various appliances submitted to it will also be made. In this connexion may be mentioned the method of producing gas used by Messrs. Brunner, Mond, and Co. The distillation is conducted at such a low temperature that the ammonia is not destroyed whilst a smokeless gas is produced from the coal. Per ton of coal about 66 lb. of sulphate are yielded. A description is given of the usual method for boiling down brine, and of the damage which is done by the evolution of acid vapours to the surrounding vegetation. A new method, that of Dr. Pick, for the evaporation of the brine by triple or multiple effect, is referred to and illustrated by a diagram (see page 617). By this method the waste steam evolved from one pan is not allowed to escape to the atmosphere at once, but passes through a coil of pipes of the next in series, and thence to the third. This latter is connected up with an air pump which produces a partial vacuum causing "a brisk ebullition to take place at a low temperature; thus condensing the steam from an adjoining vessel sets up an ebullition there, and so on."

To this report is added the separate reports of each inspector, from which a few extracts are taken.

In district No. 1. there were 49 works under inspection in which were carried on 65 different processes, the amounts of material treated being as follows:—

	Tons.
Salt decomposed .....	6,728
Bleaching powder made .....	2,565
Pyrites burned .....	24,928
Mineral phosphates and bones dissolved	33,579
Sulphate of ammonia made .....	2,511
Salt produced .....	10,600
Cement produced .....	7,487

In district No. 11. attention is called to the fact that both the sludge from the carbonators in the Chance process and the exit gases from the Claus kiln promise to be sources of annoyance, and complaints have been made on both these points. In the Widnes sub-district the inspector reports that from the former source no nuisance has occurred. The

average escape from the various wet copper extraction works was as follows:—

	Average of four preceding Years.	1889.
Average HCl in cubic foot of smoke.....	0.125	0.155
Average total acidity of cubic foot of smoke.	1.380	1.500

Tables are also given of the average exit gases of the different works, such as alkali and chemical manure, both as regards HCl and SO<sub>2</sub>.

It is stated that in one works where sulphate of ammonia was being made that the escape of hydrocyanic acid from the decomposition of cyanides present in the gas liquor was so great that on two occasions it was found to be necessary to stop work. 382 tons of sulphate were obtained from the ammoniacal liquor of the patent coke ovens.

In district No. III., including Widnes and Runcorn, there were 121 registered works made up thus:—

Alkali works.....	33
Sulphuric acid works.....	9
Chemical manure works.....	11
Gas liquor works.....	5
Nitric acid works.....	5
Sulphate of ammonia works.....	28
Chlorine works.....	2
Salt works belonging to the Salt Union, Limited...	27
Salt works belonging to independent owners.....	2
Cement works.....	1
	121

Most firms are now adopting the Chance sulphur recovery process. The amount of waste being treated in the St. Helens district is about 1,400 tons weekly. The total quantity of pyrites burnt in the district (excluding Widnes and Runcorn) amounts to 90,365 tons. No brimstone is burnt. Total sulphate of ammonia equals 4,160 tons. The amount of white salt produced is 1,154,649 tons. Very full tables of the various acid escapes are inserted.

In the Widnes sub-district there are 31 registered works, *i.e.*:—

Alkali.....	18
Sulphuric acid.....	2
Chemical manure.....	1
Sulphate and muriate of ammonia.....	4
Gas liquor.....	1
Chlorine.....	2
Nitric acid.....	1
Salt.....	1
Cement.....	1
	31

A cement works has been started for the utilisation of the lime mud from the caustic soda and Chance sulphur recovery processes. The following return is of interest:—

	Tons.
Pyrites burnt for sulphuric acid or salt cake...	132,426
Salt made into salt cake.....	209,587
Salt used in wet copper extraction.....	18,720
Bleaching powder made (including chlorate of potash).....	64,927

It has been found that, although the average of the various exit escapes is satisfactory, yet that there have been many cases of excessive escapes of usually short duration. In this district also the Chance process is making rapid progress, some 150,000*l.* having been already spent on it during the past 18 months, and 10 works are either erecting or now possess the necessary plant. Here again the main source of annoyance is not from the Chance process, but from the exit gases from the Claus kiln, these containing from 8 to 15 grains of sulphur per cubic foot of the waste gases, the loss being thus considerable. To minimise this

loss the temperature of the kiln should, as already stated, be kept as low as possible. The gases after leaving the *dry* flowers chamber should be passed through a *wet* scrubber to remove SO<sub>2</sub> and finely-divided sulphur, and thence through vessels containing milk of alkali waste to absorb the SH<sub>2</sub>, this solution then passing to the carbonators in the usual way. There are 10 Claus kilns 25 ft. in diameter in the district, and 18 or 20 more designed, and each capable of producing 15 to 20 tons of sulphur per week.

In district No. IV. tables of the various exit escapes are given. Still less brimstone than last year is used for acid making. The total amount of ammonia in its various salts manufactured during the year 1889 was 22,483 tons.

Of this amount 89 per cent. is made by the continuous process and 11 per cent. by the intermittent.

In district No. V. there are 134 registered works and 180 processes. Tables giving the averages of the various escapes are added. In the Chance process it is recommended that large kilns of 30 ft. in diameter should be employed, thereby securing a lower temperature of decomposition and a better yield of sulphur. In the manufacture of sulphate of ammonia most of the sulphuretted hydrogen evolved is treated by the open oxide of iron purifiers. In one works per ton of sulphate of ammonia produced 100 lb. of sulphur have been obtained: each ton of coal yielded 27 lb. of sulphate; thus, for every ton of coal carbonised, about 1½ lb. of sulphur have been recovered in the Claus kiln.

In district No. VI. it is reported that many complaints have been made of the fumes evolved, *i.e.*, arsenic, oxides of lead and zinc, &c., in metallurgical processes, which do not fall within the boundaries of the Alkali Act. On this point, therefore, some of the sanitary authorities have decided to petition the Local Government Board. A new process for the manufacture of ammonium sulphate is that of Mr. E. Bowen's. The ammonia evolved is passed into the waste pickle from tin works. Oxide of iron is precipitated, which may be used in the manufacture of Venetian red, and the filtrate on concentration deposits crystals of the sulphate.

In district No. VII. the results of the tests made and of improvements effected in the works are tabulated.

In sub-district No. VII. there were 108 works and 152 processes. In this district occurred the only prosecution under the Act. Six works burn brimstone and four use spent oxide as a source of sulphur. In the latter case the utilisation of the material appears to be very difficult, there being rapid and unaccountable changes taking place in the chambers. A table giving the yield of sulphate of ammonia from various coals is given in full:—

#### CONTINUOUS PROCESS.

No.	Yield of Sulphate in Pounds per Ton of Coals Carbonised (Sulphate 2½ per Cent. NH <sub>3</sub> ).	Description of Coal used.
1	25.48	Chiefly Ravensworth Pelaw with one-sixth South Yorkshire silkstones.
2	25.46	Ravensworth Pelaw, Pelton, Pelton Main, and Waldrige.
3	24.37	Chiefly Newcastle district coal.
4	23.00	Wharfedale silkstones.
5	22.80	Chiefly Aldwarke main, Stafford, Thorncliffe, Barrow and Dodsworth Collieries with one-sixth Madeley.
6	22.42	East Pontop (Newcastle).
7	21.47	Barnsley silkstones and North Staffordshire.
8	19.50	Hutton and Mandin seams, Bolden Pit Co., Durham.
9	18.00	New Pelton (Newcastle).
	22.50	Average yield.

## INTERMITTENT PLANTS.

No.	Yield of Sulphate in Pounds per Ton of Coals Carbonised (Sulphate 24½ per Cent. $\text{NH}_3$ ).	Description of Coal used.
1	24.00	Chiefly Tawkesley (Thorncliffe) with small quantity of Wigan.
2	22.00	One half Pelaw Main; equal quantities Aldwarke Main and Normanton.
3	19.00	Equal portions Ravensworth Pelaw, and South Yorkshire silkstones.
4	18.95	Equal portions Aldwarke Main and Pelaw Main.
5	18.88	Equal parts Orrell (Wigan) and Barrow (Yorks).
6	18.60	Rockingham Colliery (South Yorkshire).
7	18.50	Equal portions of Hoyland and Wharcliffe silkstones.
8	16.84	Madeley and Lyeett Collieries.
9	11.45	Equal portions of Staffordshire and Wigan.
10	9.72	Barnsley silkstones and North Staffordshire.
11	6.81	Warleigh gas coal (South Yorkshire).
	16.79	Average yield.

In Scotland the number of registered works was 129, of which 16 were alkali works, the number in 1888 being 131, of which 16 were, as before, alkali. Of separate processes there were 175, distributed thus:—

Alkali (Leblanc process) .....	11
Muriatic acid (cylinder process) .....	4
Muriatic acid (copper extraction process) .....	2
Sulphuric acid .....	32
Chemical manure .....	49
Nitric acid .....	7
Sulphate, &c. of ammonia .....	51
Chlorine .....	8
Salt .....	11
	<u>175</u>

During the year the visits paid were 567 and 280 tests were taken.

The following quantities of materials were used and produced:—

Salt decomposed:—	Tons.	Tons.
In alkali works.....	33,376	
In copper works.....	7,110	
		40,486
Pyrites burnt .....		79,665
Brimstone burnt. ....		2,180
Bleaching powder manufactured .....		8,950
Bones and phosphates used in chemical manure works.....		47,434
Sulphate of ammonia manufactured:—		
From gas liquor works .....	9,907	
From blast furnace gases .....	5,645	
From distillation of shale .....	23,953	
		39,505
Salt manufactured.....		10,600
Nitric acid manufactured.....		3,173

Whilst the production of salt and of bleaching powder has thus diminished the consumption of pyrites has increased

10 per cent., the acidity of the exit gases from the sulphuric acid works was 1.67 grains  $\text{SO}_3$  per cubic foot, or considerably less than one-half of the limit under the Act, whilst in the alkali works the average escape was 1.46 grains  $\text{SO}_3$ . The average escape of  $\text{HCl}$  per cubic foot of the chimney gases was 0.088 grains, a figure identical with that obtained for last year. From the manure works the escape was equal to 0.25 grains  $\text{SO}_3$  per cubic foot. The manufacture of sulphate of ammonia has increased by about 6 per cent., the sources whence the ammonia is derived being noteworthy when compared with the corresponding sources in England. In this report also the Chief Inspector insists upon the importance of devising means for the prevention of the production of black smoke, a source of annoyance over which the inspectors have no power. On examination it has been found that in many cases the damage done to vegetation has been in reality caused by the clouds of smoke constantly poured forth, not by any noxious gases present in that smoke.—S. G. R.

## PATENTS.

*Improvements in the Production of Magnesium Chloride and of Magnesium Oxychlorides.* F. M. Lyte, London. Eng. Pat. 6172, April 10, 1889. 6d.

THE object of the present invention is to provide a means of producing magnesium oxychloride without the usual drying and consequent loss of hydrochloric acid (see this Journal, 1887, 775—790). Anhydrous magnesium chloride is first prepared by igniting ammoniacal magnesium chloride, and is then mixed with the desired proportion of moderately calcined magnesia, which may be in powder or fashioned into balls or other shapes. By a second method, the dry double chloride of ammonium and magnesium is powdered and mixed with the dry magnesia, also in powder, and the mixture is heated carefully to a temperature not exceeding  $300^\circ \text{C}$ ., whereby all the ammonia is evolved in the free state, and the residue consists of anhydrous magnesia chloride or oxychloride, according to the proportion of magnesia added.—G. H. B.

*Improvements in and connected with the Distillation and Condensation of Ammoniacal and other Liquids, and in Apparatus therefor.* Solvay and Co., Brussels, Belgium. Eng. Pat. 8163, May 16, 1889. (Internat. Conv. October 19, 1888.) 8d.

IN the distillation of ammoniacal liquors with lime no provision has up to now been made for a preliminary separation of impurities such as carbonic acid and sulphuretted hydrogen and the like. On the contrary, all volatile products are distilled off together and then re-condensed. The apparatus shown in the figure has been devised to effect both a satisfactory elimination of the impurities and simultaneously to act as a concentrator. The working of the apparatus can be best gathered from a description of the plant itself. The weak ammoniacal liquor is run from the reservoir *h* by the pipe *n* through the coiled pipes *i* where it is heated by waste heat to about  $40^\circ \text{C}$ .; it passes thence to the washer *k* and then by the pipe *p* to the chamber *b*<sup>1</sup> and then by the pipes *f*<sup>1</sup>, *f*<sup>2</sup>, &c., to the lowest chamber *b*; from *b* it is carried by the pipes *r* and *v* to the distillation apparatus *a*; the vapours evolved now escape at *l* and then pass upwards through the coolers *c* to *c*<sup>1</sup>, where it will be best to leave them for the moment. Of the chambers *b*<sup>1</sup> to *b*, it will be clear that the lowest *b* must be the hottest, as the gases from the still are passing directly into it, and *b*<sup>1</sup> the coolest. Any carbon dioxide or sulphuretted hydrogen present in the liquors begins to be evolved in *b*<sup>1</sup> and the elimination is complete in *b*. The ammonia which is also given off in *b* is gradually re-absorbed, as it passes upwards through the cooler chambers by the "plunger caps" *e*<sup>1</sup> to *e*<sup>4</sup>. Finally the gases pass by the pipe *m* through the washer *k*, which removes the last traces of ammonia, whilst the residual gases, carbon dioxide and sulphuretted hydrogen, escape by *m*<sup>1</sup> to the exterior. Returning again to the ammoniacal distillate, this passes by

the pipes *w* and *l* to the cooler *g*. As it gives up its heat, so the weak liquors in the worms *i* as already mentioned are gradually warmed. The vessel *x* receives through the pipe *s* the purified concentrated ammoniacal liquor.—S. G. R.

*Process for the Manufacture of Chlorine which may be Employed in Combination either with the Ammonia-Soda Process or with the Leblanc Soda Process.* J. J. Alsberge, Ghent, Belgium. Eng. Pat. 8779, May 27, 1889. 6d.

THE mother-liquors of the ammonia-soda process are evaporated to dryness, the solid residue of the sodium chloride and ammonium chloride heated to 300° C. and the vapours of ammonium chloride are brought into contact with manganese dioxide at a temperature of 300° C. The chlorine combines with the manganese forming the chloride, oxygen and ammonia being evolved. The ammonia, together with the sodium chloride which was mixed with the ammonium chloride, is returned to the ammonia-soda process. The manganese chloride on gently heating with an excess of dioxide, manganese, and nitric acid yields its chlorine and is converted into manganese nitrate from which manganese dioxide and nitric acid are easily recovered by heating. In the Leblanc process the hydrochloric acid from the salt-cake furnaces may be led direct into stills containing manganese dioxide and nitric acid.—O. H.

*Improvements in the Manufacture of Nitrate of Ammonium and of a resulting Bye-product.* C. A. Burghardt, Manchester. Eng. Pat. 8841, May 28, 1889. 4d.

EQUIVALENT quantities of lead nitrate and ammonium sulphate are dissolved separately in water, and on mixing the solutions, lead sulphate is precipitated and ammonium nitrate is left in solution. The lead sulphate is separated by subsidence or other known means, and the solution is evaporated to the crystallising point, for the production of ammonium nitrate.—G. H. B.

*Improvements in the Method of and Apparatus for Condensing or Absorbing and Utilising Sulphuric and Sulphurous Acid Fumes.* W. Thorp, London. Eng. Pat. 8862, May 28, 1889. 4d.

CERTAIN sulphates and sulphides when heated evolve vapours of various sulphur acids. These are led together with a supply of air through a series of towers made of brick or stone or wood lined with lead, and filled with scrap-iron, down which water or a solution of sulphate of iron is kept running. In this way the iron is attacked by the vapours, and iron sulphate produced. When the towers are not working at a temperature of about 120°–160° F., a jet of steam must be introduced.—S. G. R.

*Improvements in or connected with the Manufacture of Sulphate of Ammonia, and Apparatus therefor.* T. and G. Wilton, Beckton. Eng. Pat. 19,225, November 29, 1889. 8d.

THE improvement consists in the employment of a steam jet pump of specified construction by which the deposit of crystallised sulphate of ammonia formed in the saturators is removed to the drainers or vessels for allowing the mother-liquor to drain away. The same form of pump is also used for circulating the absorbing liquid through the saturators, which may be of the ordinary construction.—G. H. B.

*Improvements in the Production of Solutions of Alkaline Silicate or Water-Glass, and in Apparatus therefor.* A. J. Boulton, London. From P. Sievert, Dresden, Germany. Eng. Pat. 4021, March 14, 1890. 6d.

WHEN water-glass is dissolved in water, the solution obtained is usually not clear, and must, therefore, be clarified before use. In order to avoid the inconvenience of this, it is usual to buy the material already in solution, and hence a loss arises from the increase of warehouse room required for storage. The inventor partly dissolves the lumps of alkaline silicate by the action of a current of steam, and then by washing with a spray of water or a suitable alkaline lye. The solution then flows over more of the material, and

when it has acquired the requisite strength, is constantly drawn off. The process is carried out in the apparatus shown in the figure. *a* is the outer reservoir, in which is

placed the perforated vessel *b*, within which are the lumps of water-glass. Steam is injected either by the pipe *c* or the rose *d*, and through this latter is subsequently run the water or alkaline liquid which, after passage over the silicate, issues by the pipe *e*.—S. G. R.

*Improvements in Purifying Brine.* J. C. Mewburn, London. From C. C. Peck, Warsaw, U.S.A. Eng. Pat. 4652, March 25, 1890. 8d.

Brine is first heated to boiling, to decompose the bicarbonates of calcium and magnesium. Sodium carbonate is then added to decompose calcium sulphate and the chlorides of calcium and magnesium. The precipitate is removed by filtration or subsidence.—G. H. B.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

### PATENTS.

*Improvements in and relating to Decorative Pottery Ware.* W. H. Hollinshead and H. Griffiths, Burslem. Eng. Pat. 7245, May 1, 1889. 4d.

AFTER the article has been glazed and fired it is covered with a ground layer of dry colour and again fired. In order to obtain a dull gold surface, "liquid gold" may now be applied instead of "best gold," and the article again fired. Further ornamentation may be secured by scratching away the gold to form a design and then filling in with various other colours.—S. G. R.

*An Improved Process for Depositing Metal on Glass, Porcelain, and other similar Ware.* O. P. Erard and B. J. Round, Birmingham. Eng. Pat. 7761, May 9, 1889. 6d.

IN carrying out this invention a flux of the following composition is first prepared: calcined borax, 7 parts; sand, 3 parts; oxide of lead, 4 parts; nitrate of potash, 1 part; phosphate of lime, half a part; and white arsenic, 2 parts. To every  $4\frac{1}{2}$  parts of the flux 10 parts of silver are added, the whole ground together and mixed with turpentine and

laid on as a "wash" in the ordinary way to form the required design. The whole is fired and thoroughly cleaned and the desired metal deposited electrolytically. The process is applicable to china, glass, porcelain, &c.; and not only is delicate glass strengthened by the metallic deposit, but a base is formed upon which other ornaments may be more or less easily soldered. Drawings of articles thus treated are given in the specification.—S. G. R.

## X.—METALLURGY.

*The System of Amalgamation of Gold Ores in use at the Massachusetts Institute of Technology.* R. H. Richard. Technology Quart. 3, 45—51.

See under XXIII., page 656.

*Physical Properties of Nickel Steel.* J. Hopkinson. Proc. Roy. Soc. 47, 138—139.

FROM experiments on samples of wire drawn from nickel steel containing 25 per cent. of nickel and 74 per cent. iron, by the Steel Company of Scotland, the author finds that nickel steel can exist in two states, magnetic and non-magnetic, over a range of temperature from below freezing to 580° C. The wire becomes non-magnetisable after heating to redness, whether cooled slowly or by being plunged into water, but when cooled by solid carbonic acid it resumes its magnetisable state. The electric resistance is very different in the two states, and the change in resistance effected by cooling with solid carbonic acid is almost as remarkable as the change in magnetic properties.

Of five non-magnetisable samples the highest breaking stress was 50·52 tons per square inch, the lowest 48·75; the greatest extension 33·3 per cent., the lowest 30. Of five magnetisable samples the highest breaking stress was 88·12 tons, lowest 85·76; highest extension 8·33 per cent., lowest 6·70. The broken fragments of both were magnetisable.—J. M. H. M.

*Liquation of Gold and Platinum Alloys.* E. Matthey. Proc. Roy. Soc. 47, 180—186.

IT is a well-known fact that when molten alloys of certain metals are cooled, some of the constituents separate and become concentrated either in the centre or in the external portions of the solidified mass; to this segregation the name of liquation is given. It is especially noticeable in the case of silver-copper alloys, and its importance is now being widely recognised in almost all branches of metallurgy. The author has studied the behaviour of alloys of gold and platinum. There are two methods of parting gold from silver, the one with nitric acid, the other with sulphuric acid. When platinum is present in the gold or silver, and the nitric acid process is employed, the platinum when existing in small proportions is dissolved out with the silver, leaving the gold free; sulphuric acid does not extract the platinum. As it has been found that in an ingot obtained from this residue different parts of it do not possess the same composition, it is evident that the platinum has been re-distributed by liquation. Spheres of gold containing platinum were cast in iron moulds. Parts were taken from different parts of the two hemispheres and assayed. Two alloys were treated in this way; one consisted of 880 of gold to 050 of platinum, and the other of 700 of gold to 120 of platinum. In the one case the maximum difference between the gold percentage is a variation of 032, viz., 887 on the outside against 883·8 at the centre of the alloy; and in the platinum 017·5 on the outside against 052·5 at the centre, an extreme variation of 005 is shown. In the other case the maximum difference between the gold percentage is a variation of 041, viz., 732·4 on the outside, against 694·1

at the centre of the alloy, and in the platinum 122 on the outside against 166 at the centre, an extreme variation of 0.44. The platinum, on cooling, therefore, liquates from the gold, and becomes concentrated towards the centre of the alloy. The following table represents the assays of portions cut from one end of ingots of gold and platinum, and the actual amount of fine gold obtained. The results prove that the percentage of gold in the outer portion of ingots of platinum-gold alloy does not represent the true percentage of gold in the alloy:—

Weight in Troy Ounces.	Platinum by Assay.	Gold by Assay.	Percentage of Gold by the Fine Gold actually obtained.
728.5	.111	.825	.812
355.0	.120	.660	.630
589.5	.120	.800	.780
435.0	.045	.850	.845
480.5	.086	.842	.830
473.0	.110	.830	.821

The results given were observed in platinum-gold alloyed with silver, with copper, and with both silver and copper; but, in order to prove whether or not such alloy had any tendency to carry the platinum to the centre of the mass, 900 parts of fine gold were melted with 100 parts of pure platinum, and, after repeated meltings, cast in the same mould as previously used. The result was as before, the ratio of gold to platinum on the exterior being 900 to 0.98 against 845 and 146 at the centre of the mass.—J. B. C.

*The Laws of Annealing, and its effect on the Mechanical Properties of Metals.* A. Le Chatelier. *Compt. Rend.* 110, 705—708.

THE author has observed that above a certain temperature every metal may be elongated to the point of rupture by the action of a constant load, the rate of extension depending on the magnitude of the load. This extension is produced at all temperatures in all metals, under the influence of a load sufficient to produce a permanent elongation.

From a large series of experiments on the tensile strength of metals at elevated temperatures, of which a few are given below, the following conclusions are drawn: (1) If a metal be kept at a constant temperature, the elastic strength and breaking load constantly decline towards definite limiting values at a gradually diminishing rate; (2) the limiting values are lower according as the temperature is more elevated; (3) the limiting values are higher when the initial values are high, but not to a proportionate extent.

From these generalisations it is further inferred that—

(A.) When the temperature remains constant, a metal is deformed by a given load at a gradually diminishing rate, and tends towards a determinate state of equilibrium. The magnitude of the deformation corresponding to the different states of equilibrium increases more rapidly than the loads which occasion it. The breaking load increases and the extension diminishes with the speed of loading. The deformation occasioned by shocks of the same intensity are inversely proportional to the rapidity of the shock.

(B.) When the temperature rises, without any other change occurring, the deformation increases and the resistance to breaking diminishes.

L = elastic strength in kilos. per millimetre of original section. R = breaking-load.

Copper wire hardened by drawing.

At the ordinary temperature L = 42 kilos. and R = 43 kilos.

After Heating.	At 300°.		At 350°.		At 430°.

—S. B. A. A.

*The Annealing of Metals.* Faurie. *Compt. Rend.* 110, 738.

A TEMPERATURE (A) exists for every metal beyond which the resistance continues to diminish without any further increase in malleability; another temperature (B) exists at which the malleability commences to diminish. The difference between these temperatures appears to be a function of the residual effects of previous annealings.—S. B. A. A.

*On the Use of Carbon and Coke Bricks in Blast-Furnace Hearths.* F. Burgers. *Stahl und Eisen*, 10, 112; *Proc. Inst. Civil Eng.* 1890, 56.

THE maintenance of the hearth and bottom in the blast furnace is to most smelters a troublesome and anxious task. Even in a new furnace, with the corrosive slags required by modern methods of working, the tendency is, according to the author, for the refractory brickwork of the hearth to melt and flow like butter in the summer sun; hearths with 3 or 4 feet thickness of walls, being reduced in a short time to a few inches, and necessitating the use of continuous cooling with water, which, by rendering the bricks brittle, is often attended with grave dangers from escape of molten metal through the weakened structure. This corrosive action may be well studied on the cinder-fall of the furnace, the best fire-bricks being eaten out into a gutter in an hour or two if the current of molten cinder is allowed to flow over them. These circumstances led the author to seek for a more resisting material, and finding that the lining of a furnace when blown out was often found to be protected in the hearth by a mixture of coke-dust and graphite, cemented by lime and cinder; and also that practice showed that the best lining for the cinder-channel was formed of coke-dust and ashes, he was induced to experiment with bricks containing coal- or coke-dust, graphite, and other substances in

admixture with fire-clay. The first trials were made in 1882, and the bricks made by Dr. Otto and Co., although partly defective owing to the carbon being considerably diminished in the burning, stood remarkably well against slag-corrosion. A patent was, however, refused in Germany, owing to the fact that mixtures of coke-dust and clay had been in use for a long time in the Harz lead-furnaces. In 1885, on the publication of Mr. Poncelet's paper on the manufacture of ferro-manganese (Proc. Inst. C.E., Vol. LXXXI. 408), stating that at La Voulte and Tamaris the hearths and bottoms of the furnaces were built of bricks made of gas-retort carbon, containing 1 to 2 per cent. of ash, mixed with tar and burnt, the author tried finely-ground coke, with a low proportion of ash instead of retort-carbon, and obtained equally good results. The hearth of the No. 2 furnace at Gelsenkirchen was in that year rebuilt with these bricks, and has stood the wear of a large daily make up to the present time. They have also been applied in the new furnaces at the Rhenish steel works at Rombach, and in the lead-smelting furnaces at Mechernich. The principal advantages are the suppression of water-cooling, the maintenance of the original shape of the hearth from the beginning to the end of the period of blowing, and the prevention of furnace bears on the bottom. The hearth may also be completely isolated from the foundation, as has been done by Mr. Lürman at Ruhrort and Rombach. Other advantages are to be found in the circumstance that carbon, even at the highest temperatures, expands but slightly, if at all, and that it is an exceedingly bad conductor of heat. The cost of these bricks is about 5*l.* per ton. The manufacture, which is accompanied with the production of a great quantity of soot and smoke—the first experiments, according to the author, having been comparable to lump-black making—has been carried out at the Mechernich works, which, being surrounded by barren moors, is not liable to interference from the sanitary authorities for nuisance. Mr. F. W. Hupertz, the manager of the works, has, however, devised means for rendering the soot harmless to the works and the neighbourhood, and under his management the bricks for the furnaces mentioned above, and some others, have been produced.

#### PATENTS.

*Improvements in Hydro-Metallurgical Processes.* J. H. Selwyn, London. Eng. Pat. 843, January 16, 1889. 6*d.*

THE object of the patent is to cheapen wet metallurgical processes chiefly by dispensing with the roasting of the ore generally necessary. The finely crushed ore is added to a solution consisting of nearly saturated brine, to which has been added 5 per cent. of hydrochloric acid, 10–15 per cent. of sodium or potassium nitrate or nitrite, and 1–30 per cent. of sulphur chloride, according to the nature of the ore. The mixture is kept hot and extraction is complete in from 1–8 hours, after which the liberated sulphur is collected, and the liquors containing dissolved metals syphoned or filtered off, and the gold, silver, copper, &c. which they may contain successively precipitated by known methods, electrolytical or chemical. The process may also be used for obtaining sulphur from pyrites. The chlorine evolved is collected and used to make chloride of sulphur afresh.

—B. B.

*Improvements in the Treatment of Ores for the Recovery of Metals and in Apparatus therefor.* E. B. Parnell, London. Eng. Pat. 2931, February 19, 1889. 8*d.*

THIS is a combination of appliances for raising ores to a high temperature and then quenching them in water, thereby rendering their disintegration easier. The ore is caused to pass through a chamber by means of a helix or screw-conveyor, the shaft of which is hollow and conveys air heated to 1,600 F. The ore when sufficiently heated falls into a tank from which it is removed by means of an elevator, and passes through a second chamber where it is dried by means of the waste heat from the first chamber. It then passes to rollers or stamps.—H. K. T.

*Improvements in the Wet Method of Extracting Gold.* J. H. Pollok, Glasgow. Eng. Pat. 5578, April 2, 1889. 8*d.*

THESE improvements relate to a process described in the Eng. Pat. 17,495 of 1887 (this Journal, 1889, 444) for the treatment of auriferous material by means of chlorination under hydraulic pressure. The crushed and suitably prepared ore, together with the necessary reagents, are placed in a cylinder capable of being rotated on a horizontal axis. The air in the cylinder is removed and replaced by water. The cylinder is then closed and made to rotate, hydraulic pressure being applied by means of a pipe passing through the centre of rotation at one end of the cylinder. After a sufficient time the contents of the cylinder are run out and treated in the usual way.—H. K. T.

*Improvements in the Method of and Means for Treating or Washing Crushed Ores, Coal, and Similar Materials.* O. Bilharz, Freiberg, Germany. Eng. Pat. 7500, May 4, 1889. 1*s.* 1*d.*

CRUSHED ore is sorted by means of sieves, and is then fed into one end of a channel or trough provided with funnels which collect the ore as it settles. The funnels are grouped into three sets. The first set communicate with a series of settling apparatus, each of which consists of a funnel-shaped box containing a jigger-sieve charged with granulated ore of a given grade. The boxes are connected with receptacles for receiving the classified ores. The second set of funnels of the trough are connected with similar settling apparatus from which the graded ore passes to washing tables. The aprons of the latter are provided at their edges with studs which engage in notches or recesses in the rollers. A stream of water passes to their under side to prevent adhesion with the table. The ore from the third set of funnels is treated similarly to that from the second set. Finally, the ore passing from the channel or trough is caught on a band or apron, from which it is discharged by a screw-conveyor and fed to sorting and washing apparatus. —H. K. T.

*Improvements in the Manufacture of Steel or Steel-like Compounds.* J. Riley, Glasgow. Eng. Pat. 8492, May 22, 1889. 6*d.*

THE improvements consist in the use of nickel and aluminium in the manufacture of steel. When crucible steel is being made, nickel in the form of bars, cakes, or grains is melted with iron or steel scrap. A suitable proportion of ferro-manganese is then added and finally aluminium or an alloy thereof. When a converter is used the metal is deoxidised with ferro-manganese in the usual way and then nickel is added. Finally, more ferro-manganese is added and immediately afterwards aluminium. In the open-hearth process pig iron with a rather large proportion of scrap is decarbonised in the usual way, ferro-manganese is added, next nickel in the form of bars, then more ferro-manganese, and finally aluminium or its alloy. Instead of nickel alone a compound of nickel, copper, or iron is sometimes used, preferably the matte produced in the smelting of ores from Sudbury, Ontario, America. The usual proportions in 1,000 parts of steel are: nickel 5 to 500 parts; the above matte (containing 10 per cent. of nickel and 25 per cent. copper) 25 to 250 parts; and aluminium 1 part. —H. K. T.

*Improvements in Effecting the Re-carburisation of Steel or Ingot Iron.* T. Twynam, London. Eng. Pat. 8543, May 22, 1889. 6*d.*

THIS process has for its object the re-carburisation of low carbon steel or ingot iron produced in the open hearth or Bessemer process. For this purpose the charge of metal in the furnace having been sufficiently purified is tapped and allowed to flow over sticks of wood charcoal arranged in a chute leading to the ladle. In order to prevent the charcoal from being carried forward by the metal some of the bricks in the sides of the chute are made to project. Where a high percentage of carbon is required it is advisable to employ some of the charcoal in the form of small pieces placed in the forepart of the chute, so as not to unduly

arrest the flow of the metal, and it is preferred to have the chute curved at a considerable angle or arranged in two sections so that the second section is at right angles to the first and can be readily detached from it.—H. K. T.

*Improvements in the Distillation of Sodium and Potassium and their Alloy.* W. White, Cheshunt. Eng. Pat. 9784, June 14, 1889. 6d.

SODIUM vapour as ordinarily evolved from the retort is liable to considerable oxidation during condensation, and the patentee proposes as an improvement to collect it by downward distillation. The exit tube passes through the bottom of the crucible or downwards from the end of the retort, according as one or the other is used, into a vertical receiver provided at its upper part with an opening for the escape of the accompanying carbon monoxide.—B. B.

*Improvements in the Conversion of Crude Iron into Malleable Iron and Steel, and Apparatus therefor.* H. A. Becker, Blaenavon. Eng. Pat. 9905, June 17, 1889. 8d.

This invention relates to a form of converter which, instead of being vertical and supported on trunnions, is placed with its long axis in a horizontal position, and is capable of being rotated on this axis. By this means the contents can be discharged without it being necessary to raise the mass of metal. The tuyers are placed in a line in the side opposite to the mouth of the converter, and are thus simultaneously submerged on rotating the converter. They are directed towards its closed end. By suitably placing the converter, the pressure of metal to be overcome by the blast can be easily adjusted.—H. K. T.

*An Improvement in Regenerative Gas Furnaces.* R. S. Casson, Brierley Hill. Eng. Pat. 10,050, June 19, 1889. 6d.

This invention relates to regenerative furnaces for open-hearth furnaces in iron and steel making. The improved furnace is placed *above* the melting chamber instead of below. It is claimed that there is not only a saving in cost of erection, but that it will be easier to repair and cheaper to maintain, as from its position the furnace will not be subjected to injury from slag, melted brickwork, or fluid metal.—D. A. S.

*Improvements in obtaining Precious Metals from their Ores, and in Means or Apparatus employed therein.* D. Dennis and T. K. Rose, Denver, Colorado, U.S.A. Eng. Pat. 11,788, July 24, 1889. 8d.

AN apparatus for the extraction of precious metals by the wet chlorination or bromination processes. It consists of two vessels placed one above the other, the lower ends of each being provided with filter beds of canvas and sand or other porous material, which can be lowered at will to enable the residues to be removed. Material from a mixing vessel is charged into the upper vessel, from which, after the lapse of a suitable period, the clearer portion is run into the lower vessel. Fluid pressure is now applied, the liquid in the upper vessel passing into the lower one, and thence through the lower filter bed into a suitably disposed collecting vessel. The liquid, if not sufficiently clear, can be returned into the upper vessel. The clear filtrate is now treated in the usual way.—H. K. T.

*Improvements in the Manufacture of Steel.* M. F. Coombes and A. W. Hyde, Louisville, Kentucky, U.S.A. Eng. Pat. 2981, February 25, 1890. 4d.

MALLEABLE cast iron or low-carbon steel is heated to whiteness and plunged into a solution of a carbohydrate (sugar, molasses, or honey) or of an acid resulting from the oxidation of a glycol (lactic, tartaric, or oxalic acid) with or without the addition of acids or alkalis.—H. K. T.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

*Electrolytic Separations.* E. F. Smith and L. K. Frankel. J. Frank. Inst. 1890, 129, 236—237.

See under XXIII., page 656.

### PATENTS.

*Improvements relating to Electric Accumulators or Secondary Batteries, and to the Manufacture of Plates or Electrodes therefor.* C. Pollak, Paris, France. Eng. Pat. 7428, May 3, 1889. 8d.

THE lead plates are passed between rollers made up of steel discs, suitably grooved or notched at their peripheries in order to indent the surface of the lead in a suitable way for the reception of the active material. Spongy lead is preferably made by coating the indented plate with a paste of sulphate of lead and sodium or potassium chloride, immersing the whole when dry in a solution of the same chloride, and then passing an electric current through it. A special box-like form of plate is described as suitable for railway work.—B. T.

*A Process and Apparatus for Extracting Precious Metals from Ores or Quartz.* R. L. Cousens, Johannesburg, South Africa. Eng. Pat. 8608, May 23, 1889. 8d.

THE ore or quartz is pulverised and passed over magnetised rollers, whereby iron is removed. It is then placed in a rotating barrel provided with metallic ends, together with a quantity of lime, salt, water, and sometimes a little acid, and an electric current is passed between the terminals. After a sufficient time mercury is introduced, and the rotation continued. The mixture is next run into an agitator and thence through an electrolysis vessel. The latter contains a metallic plate embedded in sand saturated with an acid or alkali. On this is placed a porous diaphragm, and on this, mercury. The latter is connected with the negative terminal of a battery, the metallic plate being connected with the positive terminal. The ore and water flow over the mercury, contact being ensured by a vertical partition extending nearly to the surface of the mercury. From the electrolyser the ore passes over an amalgamated copper plate, kept bright by felt-covered metallic pads continually passing over it, the pads and plate being connected with opposite terminals. The ore passes through several electrolysis vessels similar to the above, and finally between two metallic plates connected with the opposite terminals of a dynamo or battery, the lower plate being covered with a blanket.—H. K. T.

*Improvements in Secondary Batteries.* V. H. Ernst, Jersey, U.S.A. Eng. Pat. 13,818, September 2, 1889. (Internat. Conv. February 12, 1889.) 8d.

THE plates are such as might be made by placing a number of lead tubes horizontally and side by side, and burning the sides of contiguous tubes together. At regular intervals the tubes are cut into from the faces of the plate so as to expose the interior. The active material is packed into the tubes, a core of some loose and preferably absorbent material occupying the centre of each tube. This core allows the electrolyte to penetrate into the active material, and at the same time allows contraction and expansion of the latter to go on with safety. The plates may be arched, if desired, for greater strength, and are perforated at frequent intervals to allow of the escape of gas. (See Eng. Pat. 1281 of 1890.)—E. T.

*Process of Manufacturing Metallic Electrodes for Galvanic Batteries.* F. Marx, Berlin, Germany. Eng. Pat. 20,217, December 16, 1889. 4d.

THE inventor states that if electrodes be used, made from precipitated or electro-deposited metal, instead of from smelted metal, the voltage is increased, and a cell of the same size is able to give a much larger current. For this purpose the loose porous metal obtained by precipitation or by electrolysis is washed carefully, and then rolled or hammered into one concrete mass, from which the electrodes are formed. With zinc, a little mercury, or suitable mercury salt, is added before the mechanical treatment.

—E. T.

*Improvements in Secondary Batteries.* V. H. Ernst, Jersey City, U.S.A. Eng. Pat. 1281, January 24, 1890. (Internat. Conv. September 28, 1889.) 6d.

THE frames of the plates are cast with a number of parallel longitudinal holes through them, and other holes are made opening into these longitudinal ones in the face of the plates. Cores of suitable size are inserted in the longitudinal holes, and in the annular space round them is pressed the active material. When this material is dry the cores are removed and the plate is ready for use. These centre holes expose a much greater surface of active material to the electrolyte, and thus give greater capacity to the cell. (See Eng. Pat. 13,818 of 1889.)—B. T.

*Improvements in Portable Galvanic Batteries, and in Glow Lamps connected therewith.* A. L. Davis, Twickenham. Eng. Pat. 2364, February 13, 1890. 6d.

THE battery is made up as a drum with polygonal ends. This drum is partially filled with a suitable electrolyte, and has electrodes of semicircular shape, parallel to the ends of the drum. The drum always rests with its axis horizontal, the sides of its polygonal-shaped ends forming secure bases. In one position the plates are out of the liquid, but by rolling the drum to other positions, the whole, or part of the plates can be immersed. The drum can be divided by transverse divisions into two or more independent cells. An incandescence lamp is so attached to the centre of one end of the drum, that it can be made to throw its light in any desired direction.—E. T.

*An Improved Electrolytic Solution for Galvanic Batteries.* C. Lütke, jun., Berlin, Germany. Eng. Pat. 2819, February 21, 1890. 4d.

IN order to prevent polarisation a certain quantity of nitrate of mercury is added to the exciting fluid, consisting of a saturated solution of one or several chlorides such as those of iron, zinc, copper, &c., whereby the zinc is kept amalgamated and the electrolyte is to a certain extent regenerated.

—B. T.

## XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

*Experiments on the Preparation of Boiled Linseed Oil.* F. H. Thorp. Technology Quart. 3, 9—17.

THE particular changes which take place in the so-called "boiling" of linseed oil have received little attention. The drying of this oil is due to its oxidation, and the oxidation is greatly hastened by the "boiling." The dryer or substance added to the raw oil partially oxidises the oil during the boiling, and when a thin layer of the boiled oil is exposed to the air it rapidly hardens owing to further oxidation. The dryers most commonly used are litharge, pyrolusite, borate of manganese, and zinc white. Recently the use of oxalate of manganese has been proposed for this purpose. According to Mulder, some of the linoleic acid is converted into linoleic anhydride during the boiling. This anhydride is a tough elastic body. At the same time, some of the metal of the dryer forms a salt with the remainder of the acid, and this salt gives hardness to the varnish. Hazura and Bauer find that the rate of oxidation, and consequent hardening, of the oil, depends on the ratio of linoleic and linolenic acids present. When linseed oil is oxidised it undergoes very marked changes in its physical properties, the colour becomes darker, the oil becomes more viscous, and there is an increase in weight sometimes equalling 8 per cent. Some carbon and hydrogen are also given off. These changes occur also during the process of boiling. The present paper contains a series of experiments by the author on the effect of temperature and of the substances added in producing the essential properties of an oil varnish. The oil used was a very light yellow, cold-pressed, raw, Calcutta linseed oil. 50 cc. were used in each experiment (45·7 grms.). The measured volume was heated in a glass beaker of 150 cc. capacity or a sand bath, several beakers being heated on the same sand bath. The sand was raised round the beakers to about one-half the depth of the oil, and the oil was frequently stirred during the heating. The substances added were dried previously, and the best results were obtained with temperatures between 230° and 275°. After heating the character of the film produced was determined by coating small plates of glass with the oil and leaving them in a light room to dry. The films were considered to be dry when they could be handled without leaving finger-marks upon them. The chief points looked for were the colour and hardness of the film. The following table gives the results of these experiments:—

Dryer.	Quantity of Dryer used.	Time of Boiling.	Temperature.	Time required for Drying.	Character of the Film.
	Grams.	Hours.	°	Hours.	
Litharge.....	1.0	2½	220	6	Almost colourless.
Litharge.....	0.2	2½	250	10	Almost colourless.
Litharge.....	0.8	1½	Above 250	10	
Lead peroxide .....	1.072	1½	220	Several days.	Deeply coloured.
Lead chloride.....	1.247	2½	250—300	24	Somewhat coloured.
Red lead.....	1.024	2½	220—285	24	Deeply coloured.
Lead oxalate.....	1.323	2½	over 300	Did not dry.	
Lead tartrate .....	1.6	2½	270	24	Deeply coloured.
Lead acetate .....	1.46	2½	..	12	Somewhat coloured.
Lead borate .....	1.105	1½	220 and 300	20	Slightly coloured.
Lead carbonate.....	1.197	2	225	10	Slightly coloured.
Zinc oxide .....	0.5	2½	250	45	Nearly colourless.
Zinc sulphate.....	1.987	2½	285	15	Nearly colourless.
Zinc sulphate .....	1.5	2	Below 230	45	Yellow in colour.
Zinc acetate .....	1.0	2½	235—280	10	Colourless.
Zinc borate .....	1.0	2	240	40	Nearly colourless.
Zinc borate.....	0.5	1½	210	46	Nearly colourless.
Zinc borate.....	0.5	1½	240	46	Nearly colourless.
Zinc citrate.....	1.5	2½	230	36	Nearly colourless.
Manganese acetate.....	1.0	2½	225—250	20	Nearly colourless.
Manganese borate .....	1.625	2½	220	20	Colourless and hard.
Manganese sulphate .....	1.72	2	240	40	Colourless.
Manganese oxalate.....	1.64	2	230	40	Colourless.
Manganese acetate.....	0.5	2	225—250	20	Deeply coloured.
Manganese borate.....	0.5	1	230	20	Colourless.
Manganese acetate.....	.5	1½	225—250	20	Colourless.
Manganese oxalate.....	1.5	2½	230	36	Colourless.
Manganese sulphate .....	1.5	2½	240	36	Colourless.
Manganese oxalate.....	1.0	2½	..	48	Yellow in colour.
Manganese citrate .....	1.5	1½	230	24	Dark coloured.
Manganese tartrate .....	1.0	2½	230	24	Colourless.
Manganese formate .....	1.0	1	200	24	Somewhat coloured.

The oil after boiling was examined. For the determination of the lead a weighed amount of the oil was carbonised in a small evaporating dish and then ignited over a Bunsen lamp until all the carbon was burned off. The residue was digested with hot dilute  $\text{HNO}_3$ , filtered, the lead precipitated as sulphate, and weighed.

very similar results, but the third oil dried in half the time required by the fourth, although the latter contains more lead.

The following results were obtained in the case of the manganese salts:—

Boiled Oil.	Quantity of Dryer added.	Per Cent. of Lead in the Boiled Oil.		
		Calcu- lated.	Found.	
			I.	II.
Lead carbonate.....	1.197	2.03	1.392	1.477
Lead acetate.....	1.466	2.23	1.396	1.338
Litharge.....	0.200	0.406	0.244	..
Lead borate.....	1.105	2.03	0.982	0.998

Boiled Oil.	Quantity of Dryer added.	Per Cent. of Manganese in the Boiled Oil.		
		Calcu- lated.	Found.	
			I.	II.
Manganese sulphate ....	Grams. 1.72	1.37	0.045	0.038
Manganese borate.....	1.62	2.06	0.208	0.190
Manganese acetate.....	0.5	0.317	0.248	0.256
Manganese oxalate.....	1.5	1.034	..	0.030
Manganese tartrate.....	1.5	0.670	0.049	0.043

From the drying tests it will be seen that the first two oils in the above table dried in nearly the same time, and gave

The conclusions at which the author arrives are as follows:—

Lead dryers always give the oil a deep colour, which shows more or less in the film. Zinc dryers do not appear to act on the oil to any degree, as oils thus prepared dry slowly and do not give very hard films. Manganese dryers give the best results in all respects. Litharge gives the best results of the lead dryers, the oil being quick drying and the film hard, and if not overheated the oil is but moderately coloured. Of the zinc salts, the acetate seemed to give the best result, although the borate and citrate were nearly as good. The borate and acetate of manganese gave the best results. The acetate requires careful use, for, if heated much above 230°, it gives a deep colour to the oil, owing apparently to the formation of tar. The borate undoubtedly gives the best boiled oil for all purposes. The chlorides, nitrates, and sulphates do not make good dryers. The first two have too violent an action on the oil, while the last are very difficult to decompose, requiring a high temperature. There appears to be no advantage in the use of formates, citrates, or tartrates.—J. B. C.

#### PATENTS.

*Improvements in the Manufacture of White Lead, and in the Apparatus employed therefor.* W. Thompson, London. Eng. Pat. 4056, October 6, 1880. (Second Edition.) 11d.

THE inventor converts metallic or "blue" lead into white lead by exposure in a closed chamber to the combined action of acetic acid vapour and atmospheric air at a temperature of from 80°—120° F., for one-sixth to one-fourth of the time required for completing the conversion. Carbonic acid gas and air are subsequently supplied to the closed chamber, in addition to the acetic acid vapour.

—E. G. C.

*Improvements in the Production of White Lead or Carbonate of Lead.* R. W. E. MacIvor and F. A. Darlington, London; G. Paul, Edinburgh; and J. Allan, Harringay. Eng. Pat. 6815, April 23, 1889. 8d.

HYDRATE of lead is formed by the action of ammonium acetate on oxide of lead, and the hydrate is converted into carbonate by the injection of carbonic acid.—E. E. B.

*Improvements in and relating to the Manufacture of India-rubber or Waterproof Textile Fibres and Fabrics.* C. Dreyfus and J. Robinson, Manchester. Eng. Pat. 7090, April 29, 1889. 6d.

THE patentees ascribe the disagreeable smell of waterproofed fabrics to the use of solvent naphtha containing such impurities as naphthalene. (Ordinary solvent naphtha becomes dark brown or even nearly black when shaken with a quarter its volume of sulphuric acid at 168°—170° Tw., at the same time diminishing in bulk, proving that considerable quantities of impurities are present.) The use of pure hydrocarbons of the aromatic series, or of purified solvent naphtha, is claimed to obviate this objection.—B. L.

*Method of Preparing Iron Oxides from Ferrous Solutions.* A. J. Ramage, Widnes. Eng. Pat. 10,412, June 21, 1889. 4d.

THE ferrous solution is partially oxidised by a current of air, and lime added gradually. The ferrous-ferrie hydrate, consisting of about one-third of Fe<sub>2</sub>O<sub>3</sub> and two-thirds FeO, is filter-pressed and well washed, and then heated in a reverberatory furnace in a reducing flame. At the end of two hours it is drawn out, quenched in water, and ground. This method produces a scarlet oxide; for an Indian red, furnacing must be continued for about four hours.—F. H. L.

*Improvements in Lacquers and Varnishes.* I. M. Lamb and D. Boyde, Manchester. Eng. Pat. 10,428, June 27, 1889. 6d.

SUITABLE resins are dissolved in a solvent consisting of from 20 to 80 per cent. of fusel oil, mixed with a volatile hydrocarbon, preferably benzene or its homologues. The proportion of fusel oil is governed by the rapidity of drying desired; the smaller its proportion the faster the lacquer will dry. As an example of good lacquer the following proportions are given:—Gum damar, 1 lb.; gum benzoin, 6 oz.; solvent (as above) 6 lb.—F. H. L.

*Improvements in Preparing the Surface of Zinc Plates for Lithographic Purposes.* C. G. B. Brocklehurst, Bowdon. Eng. Pat. 12,130, July 1, 1889. 4d.

ZINC plates are faced with lead by treatment with a solution consisting of 1 oz. of sugar of lead,  $\frac{3}{4}$  oz. of nitric acid, and  $\frac{1}{2}$  pint of water, and can then be drawn or written upon by lithographic ink, and used for ordinary lithographic printing.—B. B.

*Improvements in Ink for Printing and like Purposes.* N. Browne, London. From I. Prowattain, Philadelphia, U.S.A. Eng. Pat. 15,839, October 9, 1889. 6d.

THE object of this invention is to replace the expensive oils usually employed in the manufacture of printing ink by the natural product "maltha" or semi-fluid bitumen. When applied to paper by means of type, &c., maltha has a rich dark golden colour, which imparts to bright-coloured inks a peculiar brilliancy and warmth of tone. The proportion of pigment employed varies with the shade of ink required, but with 20 per cent. lamp black a jet black is produced.

If the maltha be too thin the more volatile constituents may be removed by heat, by adding less fluid bitumen, or by the addition of powdered magnesite or resins.

For "news" inks, the maltha should have a specific gravity of from 30° to 36° B., with 20 per cent. pigment.

For "book" ink the gravity should be from 22° to 28° B., and for lithographic ink from 15° to 20° B., with 25 per cent. pigment. Only about one-half the amount of pigment used with ordinary linseed oils is necessary for mixing with the bitumen. Owing to the homogeneous character of maltha, less grinding than usual is required, and inks made therewith are practically indelible, no solvent being able to remove the impression entirely. The drying qualities are equal to the best commercial inks, and one grade of ink is equally suitable for different classes of work.—F. H. L.

*Improvements in the Manufacture of White Lead.* P. Brommer, Stuttgart, Germany. Eng. Pat. 16,706, October 22, 1889. 6d.

THIS method of manufacturing white lead is based upon the discovery made by the inventor that lead sulphate can be "very readily decomposed by heating it together with a certain quantity of soda-lye, if this quantity be determined so that the product will be, not hydrated oxide of lead, but a basic salt." If the compound formed be 2 PbSO<sub>4</sub>, Pb(HO)<sub>2</sub>, it can be at once transformed into excellent white lead, 2 PbCO<sub>3</sub>, Pb(HO)<sub>2</sub>, by heating with a suitable quantity of sodium carbonate. The by-product obtained is glauber salt. The equations representing the above changes are:—

By the improved process a very beautiful and extremely fine product is said to be obtained, having excellent covering power, while grinding and pounding are unnecessary. The cost of the process is also stated to compare favourably with that of the so-called stack or chamber process.—E. G. C.

*Improvements in Paints.* A. J. Boulton, London. From N. A. Bibikov, Albuquerque, U.S.A. Eng. Pat. 1684, January 31, 1890. 4d.

The object of this invention is to supersede the use of mineral or vegetable oils, glue, &c., in paints, by a material which is fire, water, and acid proof, and which is a non-conductor of electricity. Silicate of potash or soda is dissolved in six or eight parts of water and 25 per cent. of ground mica added. After the surplus water has evaporated a combination similar to oligoclase and andesite is formed, which may be used either alone or with various pigments.

For certain purposes 3—8 per cent. of lime may be added. —F. H. L.

*Process for the Production of Resin-acid Esters, and the Manufacture of Lacquers and Varnishes therefrom.* H. Beck, London. From E. Schaal, Germany. Eng. Pat. 2308, February 12, 1890. 4d.

ALL acid-resins may be converted into esters in the manner described in Eng. Pats. 12,807 of 1884 and 9027 of 1886 (this Journal, 1886, 523), or in the following manner.

When alcohols of high boiling point, phenols or hydrocarbons are employed, they may be allowed to flow into the melted resin-acids, the aqueous vapours being removed by means of a partial vacuum. For the conversion of the abietin acid glycerin-ester the following method is suitable. 100 kilos. rosin are heated in a copper still to from 180° to 210° C., and from 10 to 11 kilos. glycerin added in a thin stream with constant stirring, a vacuum of about 10 centimetres being maintained. When all the glycerin is added, the temperature is raised to 280° C. and the mass distilled, under as low a pressure as possible, for the purpose of separating the product into softer and harder portions.

To purify the crude esters they may be distilled in a current of benzene vapour, or in an atmosphere of carbonic acid or nitrogen. For the production of rapidly drying lacquers, from  $\frac{1}{2}$  to 2 per cent. of the ordinary lead or manganese dryers may be mixed with the esters at the end of the distillation and the mixture allowed to cool in thin layers. Suitable proportions for the preparation of such lacquers are: resin-acid ester 12 parts, turpentine oil 12 parts, linseed oil varnish 8 parts, the ester being dissolved at a temperature of 120° C.—F. H. L.

*Improvements in Apparatus for Vulcanising Dental Plates and other Rubber Articles.* C. A. Davis, Rochester, New York, U.S.A. Eng. Pat. 3399, March 4, 1890. 8d.

THE improvements consist in modifications of the boiler in which vulcanising flasks are heated. The boiler is carried by a flange resting on a ledge near the top of the stout casing or support which surrounds it, and is closed by a cover dependent from a yoke-piece by a screw passing vertically through the latter. A ball-and-socket joint at the point where the screw is attached to the cover allows it to bed fairly on to the faced top of the boiler. The yoke-piece swings in a horizontal plane, permitting the removal of the lid bodily from the boiler, making it easy to get at its contents or replace it altogether. The rubber in the flasks is subjected to an even pressure throughout the process of vulcanisation by a spiral spring confined between them and the lid of the boiler.—B. B.

#### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

*Liquid Kino.* J. H. Maiden (Curator of the Technological Museum, Sydney). Proc. Roy. Soc. Victoria, 1890, 82—83.

*Angophora intermedia* (D.C.), the narrow-leaved apple-tree, is a tallish tree, which extends from Victoria to Queensland, and is the only species of the genus which is found in the southern colony. In the following respect it is perhaps unique amongst Australian trees. Frequently, when an

incision is made into the bark, and more particularly when the knobby excrescences sometimes found on this tree are cut, there exudes a watery liquid which occasionally is almost as clear and as colourless as water, and at other times of an orange-brown or reddish-brown colour, and of the consistency of a thin extract, or even as thick as treacle. This is doubtless the substance which was sent from New South Wales to the Paris Exhibition of 1867, labelled "apple-tree juice," with the statement that it is used as a varnish; but this is not correct, as the liquid is aqueous. It is used by fishermen for tanning their nets. Mr. Kirton informed Baron von Mueller that a single tree will yield as much as two gallons of liquid, which is generally called "liquid kino." This is a modest computation, for the tree which yielded the Bangle Creek sample (*infra*) yielded from 8 to 10 gallons. The quantity is in any case by no means small, and is dependent on a variety of circumstances.

Two samples of this "liquid kino" having recently been forwarded to the Technological Museum, the author has had an opportunity of examining it.

1. From Bangle Creek, Cambewarra, N.S.W., of a clear reddish-brown colour, and in order to give precision to the tint, it is very like raw linseed oil, Strasburg turpentine, or dark balsam of Copaiba, but redder than any of them. It has a specific gravity of 1·008 at 60° F., and an acridulous smell (owing to the presence of acetic acid), accompanied by an odour not so pleasant, and reminding one somewhat of spent tan liquors. It deposits a quantity of sediment of a buff colour, consisting almost entirely of catechol. It contains tannic acid 77·2 per cent., "non-tannin" 50·8 per cent. (Löwenthal's process). The water amounts to no less than 98·3 per cent. The catechol was not estimated in this sample.

2. This was obtained from Cambewarra, but from a different locality. It is darker in colour than the preceding sample, being of a rich ruby colour. Like No. 1, it deposits a small quantity of sediment (catechol). This liquid kino had a specific gravity of 1·022 at 60° F., when received in April 1888.

The following results were obtained in December to January 1889:—Tannic acid, 3·048 per cent. (of the liquid kino, without evaporating), "non-tannin" 1·27 per cent. (a portion of liquid kino, kept in agitation so as to obtain a fair proportion of sediment, was added to water to make up the strength of one grain of liquid kino to the litre), water 96·7 per cent. (after filtration from deposited catechol). The catechol and a little phlobaphene filtered off, were found to be in the proportion of 4·95 per cent. of the original liquid kino. Ether agitated with the filtrate took up 15 per cent., of which one-third was estimated to be catechol and the rest resin.

Mr. Kirton has recorded liquid kino from the Illawarra district of New South Wales, but since there appears to be no reason why it should be found in one colony more than another, it will doubtless also be obtainable in Victoria, most likely on application to fishermen.

#### XV.—AGRICULTURE, MANURES, Etc.

*Nitrogen: Its Uses and Sources in Agriculture.* C. M. Aikman. Reprint of Lecture before the "British Chemical Manure Manufacturers' Association," London.

1. *The Relation of Nitrogen in its Different Forms to Plant Life.*—Boussingault showed that free nitrogen was not used by plants, but he was directly controverted by the experiments of Ville. Lawes, Gilbert, and Pugh, however, confirmed Boussingault's results, and the question was considered as decided till recently, when it was again brought to the front by the experiments of Hellriegel and Wilfarth. From these later experiments, the author feels justified in concluding as follows: (a.) That leguminous plants can draw their nitrogen supplies from the free nitrogen of the air in a way not possible to other plants. (b.) That this

absorption of free nitrogen is not effected directly by the plant, but is the result, so to speak, of the joint action of certain micro-organisms present in certain soils and the plant itself. (c.) That this fixation is connected with the formation of minute tubercles on the roots of the plants of the leguminous class, and that these tubercles may be the home of the fixing organism. (d.) That these fixing micro-organisms are not present in all soils.

In 1876 Berthelot discovered that free nitrogen was being continually fixed by minute organisms in certain soils under the influence of silent electrical discharges. As much as 25 lb. per acre per annum may be so fixed. This fixation does not occur during the winter (compare Appendix).

Although plants, under favourable circumstances, may absorb ammonia and simple forms of organic nitrogen (e.g., urea), nitric acid must undoubtedly be considered as practically the final form of nitrogen for the plant, and into this all other nitrogen must be converted before it becomes available as plant food. Nitrification is, therefore, of the utmost importance. The nitrifying organism will only work in the upper layers of soil, where oxygen is sufficient. Warmth, moisture, organic matter (compare Appendix), lime, and certain other mineral matters are also necessary for its growth. Much organic matter, ferrous oxide, and sulphides, by appropriating oxygen, are fatal to nitrification.

2. *Natural Sources of Gain of Nitrogen.*—These are:—(a.) In the air; free nitrogen (available only in some cases), ammonium nitrate and nitrite, and ammonia; about 4 lb. of nitrogen per acre per annum, in the form of these compounds, are washed down in the rain, according to Warrington. (b.) In the soil; organic compounds containing nitrogen, ammonia, and nitrates; the organic nitrogen is rarely much less than 0.1 per cent. (= 3,500 lb. per acre to 1 ft. deep), and in rich soils may be more than double this amount; the ammonia rarely exceeds 0.0006 per cent.; the nitrates vary, as much as 55 lb. per acre have been found in the first 20 in. of cultivated soil left fallow.

3. *Natural Sources of Loss of Nitrogen.*—Drainage is the chief of these. Nitrates are incapable of being retained by the soil, and are rapidly washed out. The amount of loss may be imagined by the amount of nitrates removed by the rivers. According to Storer (Agricultural Chemistry, 1, 318) the river Rhine discharges daily 220 tons of saltpetre, the Seine 270 tons, and the Nile 1,100 tons (compare Appendix).

Loss of free nitrogen is constantly occurring where large quantities of organic matter decay and oxidation is incomplete, but it amounts to very little.

Retgression of the nitrogen of nitrates to an organic form by the agency of a denitrifying organism may take place; this would probably explain the action of nitrate of soda as a manure in the second year, an action which has been noticed in some cases.

4. *Artificial Sources of Supply and Loss of Nitrogen.*—(a.) *Losses.*—The following table shows, approximately, the amount of nitrogen removed from the soil by the total produce of wheat, barley, and oats in Great Britain according to the last agricultural returns:—

		Containing Nitrogen.	Equal to Sulphate of Ammonia.	Equal to Nitrate of Soda.
Wheat.....	Bushels. 76,224,940	Tons. 37,432	Tons. 176,465	Tons. 227,296
Barley.....	69,948,266	27,324	128,813	165,896
Oats.....	150,789,416	56,835	267,936	341,010
Total.....	296,962,622	121,591	573,214	734,172

It is impossible to estimate how much of this nitrogen is lost to the land. The straw, which is always returned to the land, contains less than one half the nitrogen in the grain. This loss is almost entirely due to our present system of disposal of sewage; taking the amount of nitrogen in the excreta of each individual as  $\frac{1}{2}$  oz. per diem (according to Heiden 1.7 lb. in the solid excreta and 9.7 lb. in the liquid excreta = 11.4 lb. per person per annum), 365,000,000 lb.

of nitrogen per annum will be voided by the entire population (in 1878) of the British Isles, "91,000,000" of which will be lost in London alone. The amount of nitrogen returned to the land as seaweed and fish is very small. Much free nitrogen has been shown to escape from sewage.

The nitrogen of explosive compounds is entirely lost, as it is ultimately converted into free nitrogen; it amounts to some 10,000,000 lb. per annum.

Loss of nitrogen in badly-kept farmyard manure undoubtedly occurs. In milk, sold off the farm, there is another loss of nitrogen. In the milk of a cow giving 2,000 quarts (American quarts, each of which = 57.75 cub. in.) per annum there are 22 lb. of nitrogen, the 2,450,444 cows in milk in Great Britain in 1888 would thus remove 54,000,000 lb. of nitrogen.

(b.) *Supplies.*—Our total consumption of bones is estimated at not less than 100,000 tons per annum; if the percentage of nitrogen in them be taken at 3—4, there will be 3,000—4,000 lb. of nitrogen applied in this form to the soil per annum. 60,000 out of the 100,000 tons are produced at home, and of this some 22,000 are obtained in and around London.

The following table gives the importation of guano into this country; the earlier shipments contained 13—14 per cent. nitrogen, but now they contain not more than 6 per cent. :—

PERUVIAN GUANO IMPORTED INTO UNITED KINGDOM.

Year.	Tons.	Year.	Tons.
1865	213,024	1880	58,631
1870	247,028	1881	33,333
1871	144,735	1882	27,382
1872	74,964	1883	36,713
1873	135,895	1884	15,802
1874	91,346	1885	..
1875	86,042	1886	28,733
1876	158,674	1887	5,784
1877	111,835	1888	16,446
1878	127,813	1889	17,000
1879	45,475		

*Nitrate of soda* is formed in beds at a depth of 10 in. to 16 ft. in layers 6 in. to 3 ft., often quite near the surface, but generally covered with a layer of "costra," a conglomerate rock. The crude stuff, known as "caliché," contains 20—60 per cent. of NaCl and other impurities. No beds occur nearer than 15 miles to the sea; the most distant are about 90 miles; the districts are rainless and without vegetation. They probably result from the decay of vast quantities of seaweed. Legrange estimates the quantity in the beds as some 100,000,000 tons. Nitrate was first exported in 1830, when only about 800 tons were sent out.

IMPORTS OF NITRATE OF SODA INTO THE UNITED KINGDOM, 1873—1889.

Year.	Tons.	Year.	Tons.
1873	124,000	1882	96,000
1874	108,200	1883	103,700
1875	161,900	1884	103,700
1876	160,800	1885	109,400
1877	69,600	1886	75,100
1878	104,400	1887	83,100
1879	55,500	1888	103,100
1880	48,300	1889	120,000
1881	54,800		

The above table represents the total imports; the quantity used last year in agriculture may be roughly estimated at 100,000 tons, which is less than some 15 years ago, the nitrate containing 15—16 per cent. of nitrogen.

*Sulphate of ammonia* has been rapidly increasing in production:—

SULPHATE OF AMMONIA PRODUCED IN THE UNITED KINGDOM FROM 1870 TO 1889.

Year.	Tons.	Year.	Tons.
1870	10,000	1880	60,000
1871	41,000	1881	65,000
1872	42,000	1882	72,000
1873	43,000	1883	75,000
1874	45,000	1884	87,000
1875	46,000	1885	97,000
1876	48,000	1886	106,500
1877	52,000	1887	113,700
1878	55,000	1888	122,800
1879	57,000	1889	132,000

80,000—90,000 tons are exported and 30,000—40,000 are consumed at home. The sources and respective quantities produced for the last four years are given below. (Compare L. Mond, this Journal, 1889, 506.)

	1886.	1887.	1888.	1889.
Gas works .....	82,500	85,000	93,000	100,000
Iron works .....	4,000	5,000	5,300	6,000
Shale works .....	18,000	21,000	22,000	23,000
Coke and carboursing works ..	2,000	2,700	2,500	3,000

*Fish guano*.—Some 5,000 tons containing about 9 per cent. nitrogen are probably annually imported, and about 10,000 tons containing about 8 per cent. nitrogen are produced at home.

*Meat meal and dried blood* are imported to the extent of about 5,000 tons, at 7—8 per cent. nitrogen, and about 10,000 tons at 12 per cent. nitrogen, are produced at home per annum. (Compare Appendix.)

The production of *shoddy* in this country is—

1,200 tons containing 8—12 per cent. nitrogen.
6,000 " " 6—8 " "
5,000 " " 5—6 " "

*Scutch*, the waste products of glue and leather factories, contains about 7 per cent. nitrogen.

*Horns, hair, bristles, and hoofs*, all of which contain about 14 per cent. of nitrogen, and *leather* are probably but little used.

*Oil-seeds and oil-cakes* for cattle feeding of course supply much nitrogen, the former containing about 3—4 per cent., and the latter 3—6 per cent. In 1889, 256,296 tons of oil-cake, about 370,000 tons of linseed, 80,000 tons of rapeseed, and 289,413 tons of cotton-seed were imported.

There were also used for cattle feeding in 1887: wheat, about 2,800,000 tons; maize, 1,560,000 tons; peas and beans, 870,000 tons; oats, 720,000 tons.

The *straw* imported in 1887 amounted to 52,393 tons; of *peat moss litter* there are no statistics.

In discussion the President (Mr. Voss) remarked on the decrease in the consumption of nitrogen in artificial manure during the last 15 years. In 1873 the total nitrogen used in the various manures mentioned in the paper amounted

to 34,000 tons; at present, however, only 28,000 tons are used. The great fluctuations in the prices of manures, and the increased use of cakes for cattle, explains this to a great extent. Dr. Sibson thought that the chief supply of ammonia in vegetation comes from the subsoil, where it is held absorbed by the clay, &c., having been collected and stored by the rain for thousands of years. Mr. Brown had tried experiments on the growth of leguminous plants and found that they grew well in the absence of any source of nitrogen except the atmosphere. Mr. Bernard Dyer pointed out that if the moderate dressings of  $\frac{3}{4}$  cwt. and 2 cwt. per acre of nitrate of soda were applied to the whole area of wheat and mangel crops respectively in the United Kingdom, about 350,000 tons of that manure would be used. He found it difficult to understand why the use of nitrogenous manures had fallen off; much land was undoubtedly under-farmed, owing to lack of instruction to the farmers.

An appendix contains letters which the author has received from several agricultural chemists. Sir J. B. Lawes estimates the loss of nitrogen on our soils at from 15 to 20 lb. per acre per annum. He is of opinion that the fact may be accepted that leguminous plants do, under certain conditions, obtain nitrogen from the atmosphere through the agency of germs; on the other hand, it is certain that these plants do take enormous quantities of nitrogen from the soil, so that the agricultural question becomes more complicated than it was before. There is no reason to think that the soil of the permanent wheat field at Rothamsted has obtained any appreciable amount of nitrogen from the atmosphere; but soils covered with vegetation undoubtedly do gain nitrogen slowly. Mr. Warington urges that Berthelot has not yet proved that a naked soil can gain nitrogen under the influence of electricity, but has simply shown that certain vegetable substances can do so, and has argued that soils should do the same. That free nitrogen is absorbed by an uncovered soil can hardly be concluded at present, for Schloesing has repeated Berthelot's experiments and found no evidence of such absorption. It is doubtful whether nitrification requires organic matter, and certain that it takes place in solutions to which no organic matter has been added. The loss of nitrogen by drainage in England is somewhere about 8 lb. per acre per annum. Dr. Stutzer thinks the estimate of nitrogen lost as nitrates in rivers, given in the paper, excessive. Messrs. R. D. Steele and Co. fix the imports of meat meal and dried blood at 2,500 tons per annum, and the home production at 7,000 tons. Ground hoof is a good deal used now. Fish guano should be estimated at 7,000—8,000 tons per annum. —A. G. B.

*New Experiments on the Question of the Fixation of Free Nitrogen.* Sir J. B. Lawes and Dr. J. H. Gilbert. Proc. Roy. Soc. 47, 85—118.

EXPERIMENTS similar to the well-known ones of Hellriegel, which were commenced in 1883, have been made by the authors at Rothamsted in 1888 and 1889. The results fully confirm Hellriegel's statements, and show large gains of nitrogen over that contained in seed and manure in many cases of leguminous plants grown in prepared sand or soil containing known percentages of nitrogen. The cases showing this luxuriant growth and increase in nitrogen were those in which root tubercles were well developed, and this was brought about by adding a little aqueous extract of the crushed tubercles to the prepared pots, or by watering them with the washings of soil in which similar leguminous crops, provided with root tubercles, had grown. The authors therefore are now prepared to endorse the conclusion drawn from Hellriegel's experiments "that although chlorophyllous plants may not directly utilise the free nitrogen of the air, some of them at any rate may acquire nitrogen brought into combination under the influence of lower organisms, the development of which is apparently, in some cases, a coincident of the growth of the higher plant whose nutrition they are to serve."—J. M. H. M.

*The Assimilation of Carbon by Green Plants from Certain Organic Compounds.* E. H. Acton. *Proc. Roy. Soc.* 47, 150—175.

THE observation of A. Meyer that starch is formed in the dark when solutions of glucose, glycerin, saccharon, or inulin are supplied to growing shoots, holds true when these solutions are supplied to roots or direct to the leaves. Starch is also formed when "soluble starch" is supplied direct to the leaves, but not when it is supplied to the roots, and when "humus extract" is supplied to roots, but not when supplied direct to leaves. It is not formed at all from acrolein or its compounds, allyl alcohol, dextrin, glycogen, aldehyde or its compounds, levulinic acid, or artificial humus made by action of alkalis on sugar. Glucose is more readily taken up from a 0.5 per cent. solution than saccharon. All the glucose can be withdrawn from a 1 per cent. solution if the roots are left in sufficiently long.

—J. M. H. M.

*Catalytic Formation of Ammonia from Nitrates.* O. Loew. *Ber.* 23, 673—680.

THE reduction of nitrates to ammonia is performed readily by moulds, and, as the author has proved, if ethyl alcohol (0.2 per cent.) be added, and the access of air cut off by means of a mercury joint, the reduction is carried on at the expense of the alcohol. The author submits that this result can only be explained if it is accepted that the reduction is caused by an atomic motion of the living protoplasm, that the dormant power of the living cell is converted into active, the atomic motion being transferred to the potassium nitrate as also to the alcohol.

In order to prove the correctness of this assumption, the author conducted a series of experiments with platinum black in place of the moulds. He holds that the oxygen of

the platinum black is not merely condensed on the surface of the platinum, but that the peculiar power it possesses is due rather to an atomic motion. In confirmation of this may be cited the fact that if oxygen be merely compressed it will not spontaneously oxidise alcohol and hydrogen.

Pure crystallised dextrose (5 grms.) and potassium nitrate (0.5 grm.) dissolved in water (100 cc.) were warmed to 60°—65° for six hours with 50 grms. of very active platinum black. The resulting acid liquid was filtered, concentrated, and treated with slight excess of milk of lime, which caused an immediate evolution of ammonia. Another, and at the same time quantitative experiment not only confirmed this result, but also showed that 45.6 per cent. of the nitrogen of the potassium nitrate was thus reduced to ammonia.

Experiments were also made to show that the reduction was not caused by any aldehydes, possibly formed from the dextrose; and these gave a negative result. Indeed, the reducing power of formic aldehyde was tried on nitrates and proved itself to be without any such power.

Other experiments, in which the platinum black was omitted, showed that it is undoubtedly the agent by means of which this reduction is brought about, and the author concludes that although the acids, chiefly gluconic and saccharic, are formed by the oxidation of the dextrose by the oxygen of the platinum black, yet another part of this causes a certain atomic motion in the nitrate and dextrose molecules resulting in the reduction of the nitrate.—J. W. L.

*Truffles.* A. Chatin. *Compt. Rend.* 110, 376—382; and 435—440.

THE author gives analyses of truffles from several localities, together with that of the soils in which they were found. In the following table the most complete analyses of the truffles are given. The localities are shown in the headings:—

	Saygnac les Eglises (Dordogne).	Souillac (Lot).	Dégagnac (Lot).	Chamont (Haute-Marne).	Dijon.	Tullins (Isère).

The trace of iodine is appreciable by comparison with titrated and coloured liquids at about  $\frac{1}{20}$  mgrm. (per 100 grms.?).—J. M. H. M.

*Absorption of Ammonia from the Air by Soil.* T. Schloesing. Compt. Rend. **110**, 429—434; 499—504.

FROM 1886—90 the author has made a number of experiments proving the absorption of ammonia from the air by soils of very different character, in quantities representing a gain of nitrogen to the soil of from 15 to 50 kilos. per hectare of surface per annum. The experiments were made by exposing known weights of soil in glass dishes in a wooden flue opening into a chimney through which a current of air was maintained by gas burners. The air was filtered before entering the flue through a sheet of perforated metal, to prevent access of birds, insects, &c.; and the amount of nitrogen carried in by fine dust was estimated by placing an empty jar of the same size as the others in front of them, and determining the nitrogen contained in the dust deposited in this jar at the termination of the experiment. The increase of ammonia absorbed, owing to the constant current maintained, over that which would have been observed with air subject only to the ordinary disturbance, was allowed for by exposing two vessels of dilute acid, with known surface, one inside the flue and subject to the current of air, and the other outside the apparatus altogether. Thus the nitrogen contained in the dust amounted to 1.9 kilos. per hectare per annum, and the extra ammonia due to agitation of the air amounted to from 0.534 to 0.637 of the net gains of the soils after deducting the 1.9 due to dust. After making allowance for both of these sources, the various soils gained, as stated above, nitrogen to the extent of 15—50 kilos. per hectare per annum. That this gain was not from free nitrogen brought into combination was shown by the fact that some of the soils experimented with were the very same samples with which the author has obtained so many negative results as to the fixation of free nitrogen, but still more conclusively by a check sample of soil, placed amongst the others, but fitted with a cover to prevent access of the current of air, the crown being pierced with a little hole so that ordinary diffusion could take place. This sample gained in 495 days only 0.5 mgrm. of nitrogen per 100 grms. of soil, whilst the other uncovered samples exposed with it gained from 3.6 to 12.9 mgrms. of nitrogen per 100 grms. The nitric nitrogen, ammoniacal nitrogen, and total nitrogen were determined in each sample of soil before and after the exposure. The absorption of ammonia is greatest when the soils are frequently moistened, because then the ammonia is nitrified as fast as it is absorbed, but it takes place even when the soils are kept so dry that no nitrification occurs. The absorption is shown by subsoils as well as surface soils, by soils poor and rich in nitrogen, and by those containing as much as 37 per cent. of calcium carbonate as well as by those nearly free from lime.

—J. M. H. M.

*A Coleopterous Insect attacking the Tunisian Vines.*

A. Laboulbène. Compt. Rend. **110**, 539—540.

AN addition to the 130 species of insect enemies of the vine figured in V. Mayet's "*Les Insectes de la Vigne*" (Paris, 1890). It proves to be *Ligniperda fransisca* (Fabricius), and attacks the pith of the stems after the harvest, in October, leaving hollow stems of bark. The shoots attacked should be cut off and burnt before the insects escape.

—J. M. H. M.

*Presence of Boric Acid in Plants.* E. Bechi.

Bull. Soc. Chim. 1890, **3**, 122.

WITH regard to the communications of Lippmann and of Crampton (this Journal, 1889, 569) relating to the presence of boron in plants, the author points out that he discovered this fact long ago in plants grown on Boroniferous

soils, and showed that the ash of beeches from Vallombrosa, Tuscany, contained as much as  $\frac{1}{100000}$ th of boric acid. He intends publishing his results.—D. A. L.

*Manurial Experiments with Beans.* H. Patensen. Hildesheimer landw. und forstw. Vereinsblatt, **29**, 85—89, and 95—98.

BEANS were grown on a heavy undrained loam, given to forming weather-pan, and in a level, moist situation; during the preceding years it had grown sugar beet with artificial manures, and the immediately preceding crop was oats with ammonia superphosphate and Chili saltpetre, which had yielded a very good harvest. These experiments were conducted to test the value of farmyard manure for beans. The farmyard manure employed contained per cent. N, 0.5;  $P_2O_5$ , 0.26;  $K_2SO_4$ , 0.63; CaO, 0.7, and the manuring and results were as follows:—

Manuring.	Average Yields from Two Sets of Experiments in Centners per Morgen.	
	Seed.	Straw, &c.
Unmanured .....	5.3	11.3
8 fuder (160 centners) farmyard manure..	11.5	18.0
3 ctrs. Thomas' powder and 2 ctrs. kainite	6.0	12.7
1 ctr. Chili saltpetre .....	5.1	11.1

The farmyard manure only, yielded a profit, which demonstrates its efficiency for the purpose. The partial manuring was not successful. The plants developed about the same on all the plots, but on the farmyard manure plots the beans were longer and the leaves were nearer together, although they were neither larger nor more numerous. The number of blossoms was about the same on all plots, but on the unmanured and mineral manured plots the blossoms to a large extent fell off without fertilising. Again, the mineral manured plots fell victims to the attacks of parasites (*Erysipe Martii*, *Peronospora viciae*, and *Uromyces fabae*), but the farmyard manure plots were free. The author points out that perhaps in many instances where failure of crops is attributed to these pests, it may be to some extent due to want of proper manure. The plants on all the plots had the healthy blue green colour, and showed no signs of want of nitrogen.—D. A. L.

*Hildesheim Manurial Experiments with Beet in 1889.*

K. Müller. Hildesheimer landw. w. forstw. Vereinsblatt, 1890, 2—5.

SINCE 1885, experiments have been conducted annually on various farms to ascertain the suitability of various manures for the Hildesheim soils. The reliable experiments last year gave the following results per morgen, taking the beet at a value of 1.25 marks, and Chili saltpetre at 10 marks per centner:—

Manuring.			Nett Profit Marks per Morgen.	Percentage of Sugar.
Centners Chili Saltpetre.	Pfund, $P_2O_5$ .			
	Soluble.	Thomas Slag.		
0	0	0	..	15.8
2	0	0	16.87	15.7
2	15	0	28.35	15.9
2	30	0	25.08	16.1
2	0	30	31.90	16.0
3	30	0	..	15.8

The results agree with those of the previous year in showing that, under the prevailing conditions, twice as much nitrogen as phosphoric acid produces a better result than applying twice as much phosphoric acid as nitrogen. In one case, Chili saltpetre alone produced no result, but yielded a great increase with 15 pfd. of phosphoric acid, and even in this case the use of 30 pfd. of phosphoric acid did not increase the profit. The Thomas slag acted well, although sown in the spring; better results would be obtained by sowing in the autumn. It is pointed out that since the commencement of the experiments Chili saltpetre has acted always in dry and in wet seasons, while the phosphoric acid was more active in wet than in dry seasons. The use of

potash in addition to the nitrogen and phosphoric acid gives a further increase in yield, although the nett profit is not so large, owing to the cost of potash.

Other experiments are in progress.—D. A. L.

*Results of Manurial Experiments on Mangels, Maize, and Meadow Grass.* J. Samek. Tiroler landw. Blatter, 1890, 42—43.

THE following are the results obtained with "mammoth" mangel on a tenacious deep soil derived from the weathering of clayey limestones and poor in potash; the second year after a liberal manuring with dung.

Manuring in Kilos. per Hectare.				Yield per Hectare, M.-Ctr.		Profit from Manuring.	
18 per cent. Superphosphate.	Ammonium Sulphate.	Chili Saltpetre.	48 per cent. Potassium Sulphate.	Roots.	Leaves.	Fl.	Kr.
0	0	0	0	320	54	..	..
400	0	0	0	428.8	44	38	5
400	115	0	0	512	58	63	7
400	0	150	0	563	65	92	72
400	115	0	75	537	71	70	9
400	0	150	75	572	72	89	24
400		220 blood meal		468	60	42	47

The nitrate was applied in two lots. The potash is necessary even if not profitable.

The results of growing maize on a shallow sandy medium soil rich in potash, consisting of Adige river alluvium, are given in the following table. The experiments were

made the second season after farmyard manure; the phosphates and potash were sown in the furrows before the seed, the nitrate half before the seed, half when banking up, as in the case of the mangels.

Manuring, kilos. per Hectare.				Yields.		Profit.			
Superphosphate.	Ammonium Sulphate.	Sodium Nitrate.	Potassium Sulphate.	Maize Grain per Hectare.	Hay M.-Ctr. per Hectare.	Maize.		Hay.	
						Fl.	Kr.	Fl.	Kr.
0	0	0	0	27.5	53.5	..	..	..	..
300	115	0	0	36.1	..	6	10	..	..
300	0	150	0	43.2	65.0	46	70	47	..
300	60	60	0	40	..	30	30	..	..
300	0	0	0	..	55.1	..	..	34	50
300	0	150	100	..	81.9	..	..	81	75

The meadow experiments were conducted on a shallow calcareous loam poor in potash, which in the previous year had been well manured with farmyard manure, and for which the present wet season was favourable. The herbage on the manured plots was chiefly leguminous, on the unmanured gramineous. Both the potash and phosphate acted well. Both on the roots and on the maize the nitrate proved better than the ammonium salts.—D. A. L.

*The Nitrifying Process and its Specific Ferment.* Percy F. Frankland and Grace C. Frankland. Proc. Roy. Soc. 47, (289) 296—298.

THE process of nitrification has been practically studied for centuries, but it was first in the year 1878 that it was shown by Schloesing and Müntz to be dependent upon the presence of certain minute forms of life, or micro-organisms, or in other words to be a fermentation change.

The authors have been engaged during the last three years in endeavouring to isolate the nitrifying organism,

and the present memoir gives in detail an account of the numerous experiments which were made in this direction.

Nitrification, having been in the first instance induced in a particular ammoniacal solution by means of a small quantity of garden soil, was carried on through 24 generations, a minute quantity on the point of a sterilised needle being introduced from one nitrifying solution to the other. From several of these generations, gelatin-plates were sown and the resulting colonies inoculated into identical ammoniacal solutions, to see if nitrification would ensue; but, although these experiments were repeated many times, on no occasion were they successful.

It appeared, therefore, that the nitrifying organism either refused to grow in gelatin, or that the authors had failed to find it, or that, growing in gelatin, it refused to nitrify after being passed through this medium.

Experiments were, therefore, commenced to endeavour to isolate the organism by the dilution method. For this purpose a number of series of dilutions were made by the addition to sterilised distilled water of a very small quantity

*The Reduction of Acids of the Sugar Group.* E. Fischer.  
Ber. **23**, 930—938.

THE reduction of oxy-acids rich in oxygen by means of sodium amalgam, which was described in a previous paper (this Journal, 1889, 994) furnishes a ready means for the synthesis of numerous sugars and allied bodies. Only those acids which form lactones are susceptible to this mode of reduction, and the ease with which reduction takes place seems to be proportional to the stability of the lactone. In fact, any body which prevents the formation of the lactone, also hinders the progress of the reduction. In the case of acids which form no lactones, reduction may, in some instances, be effected by employing an ether of the acid. The anides of oxy-acids are not affected by sodium amalgam. The mono-basic acids all yield sugars on reduction, whilst the di-basic acids are converted into aldehyde acids. In conjunction with Kiliani's reaction for the preparation of cyanogen addition compounds, this reduction process renders possible the building-up of sugars richer in carbon from other known sugars. For instance, from the carboxylic acids of mannose, galactose, and glucose, three well characterised sugars,  $C_7H_{14}O_6$ , are obtainable. By the addition of HCN, &c., they yield three acids,  $C_8H_{16}O_7$ , from which, by reduction, three sugars,  $C_8H_{16}O_6$ , may be prepared. The process is also applicable to those saccharoses which contain an aldehyde group. The author proposes to name the new sugars thus obtained, heptose, octose, nonnose, &c., their corresponding alcohols, heptite, octite, nonnite, &c., and so on. In order to indicate their origin, the name of the sugar from which they are derived is prefixed, thus: manno-heptose, manno octose, manno-heptite, gala-heptose, &c.

The following is a brief account of the results actually obtained by the reduction of sugar acids:

The reduction products of the three (*d*, *i*, and *l*) *mannonic acids* have already been described (this Journal, 1890, 527—528).

*Galactonic acid* yields galactose.

*Mannose carboxylic acid* yields, according to Passmore, *manno-heptose*, which is crystallisable and dextro-rotary. Its phenylhydrazone is difficultly soluble in cold water and melts at 188°—190° C. Its osazone forms fine yellow

needles, insoluble in water, melting at 198°—200° C. On further reduction the sugar is converted into an alcohol,  $C_7H_{16}O_7$ , which is identical with *Persëit*, for which Maquenne has established the same formula.

By means of the cyanogen reaction *manno-heptose* is convertible into *manno-octonic acid*, which forms a crystalline lactone melting at 167°—170° C., and possessing the optical activity,  $[\alpha]_D = -43.58^\circ$ .

Manno-octose, prepared from the acid, is dextro-rotary and forms a difficultly soluble phenylhydrazone melting at 212°—213° C.

*Glucose-heptose*, prepared from the corresponding acid, crystallises from water in beautiful plates, which melt at 190° C. with decomposition. Its phenylhydrazone is easily soluble in water, and its osazone forms golden yellow needles melting at 197° C. The sugar readily combines with HCN, and the *gluco-octonic acid* thus obtained yields a crystalline barium salt.

*Gala-heptose*, from *galactonic acid*, yields a difficultly soluble hydrazone, melting at 199° C. with decomposition. The osazone melts at 220° C. The sugar combines readily with HCN.

According to Piloty, *rhamnose carboxylic acid* yields on reduction *methyl-herose*,  $CH_3(CHOH)_5CHO$ , which melts at 180°—181° C. Its hydrazone is easily soluble. With HCN it forms *methyl-heptonic acid*, the lactone of which is crystalline. *Methyl-heptose* forms a difficultly soluble hydrazone.

*Levulose carboxylic acid* gives two peculiar sugars which are being further examined.

According to Reinbrecht, milk sugar yields with HCN an acid which has one carbon atom more than *lacto-bionic acid*. On reduction the acid is converted into a sugar probably possessing the formula  $C_{13}H_{24}O_{12}$ .

*Saccharic acid* by careful reduction is converted into an aldehyde acid, which has not been obtained in a crystalline state. It reduces Fehling's solution and is very similar in all respects to *glucuronic acid*.

*Mucic acid* is not itself reducible, but its ethyl ether is converted by sodium amalgam into an aldehyde acid, which forms a pale yellow syrup, reduces Fehling's solution, and on oxidation is converted into mucic acid.—H. T. P.

Formula for calculating the above table:  
 (Initial specific gravity × initial degree Brix) = (specific gravity of the syrup × degree Brix of the syrup) × 100 = per cent. syrup obtained.  
 100 - per cent. syrup = per cent. water evaporated.

## ERRATUM.

In the May number of this Journal, page 528, line 34 from top, for "König" read "Hönig."

## XVII.—BREWING, WINES, SPIRITS, Etc.

*Diminution of the Fermenting Power of Saccharomyces Ellipsoideus by Copper Salts.* A. Rommier. Compt. Rend. 110, 536—538.

THREE to four mgrms. of copper, added as sulphate to 40 cc. of sterilised grape juice seeded with pure cultures of *S. ellipsoideus* greatly retarded the development of the fermentation. As it is this ferment which communicates certain qualities to high-class vintages, the spraying of vines with copper preparations to prevent mildew may thus have an injurious influence.—J. M. H. M.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

### (A.)—CHEMISTRY OF FOOD.

#### PATENTS.

*Composition for Coating Coffee.* F. W. Moore, Wilmington, Delaware, U.S.A. Eng. Pat. 5033, March 22, 1889. (Internat. Conv. August 25, 1888.) 4d.

THE mixture consists of the following ingredients:—Milk or condensed milk, ground or powdered glue, "liquid glycerin," and refined lard, and in some cases bicarbonate of soda, fine table salt, and vinegar are also added.—F. W. T. K.

*Improvements in the Method of Preserving Milk.* A. Vászrhelyi and J. Jámhor, Budapest, Hungary. Eng. Pat. 6984, April 26, 1889. 8d.

FRESH and sound milk not later than one hour after milking is placed in jars made of a suitable material.

The jars are made in three parts. The bottom part, in which eventually the milk is preserved, is first filled; the other two parts together form what is called the mediator. This is screwed into the bottom can and acts as a filler. For this purpose, even after the bottom can is filled, the top filler is kept three parts full.

When a number of cans and mediators have been fixed in a tray they are filled and then the whole is lowered into water in a suitably arranged boiler. The milk is heated up to 76°—77° K. As soon as the mediator and can are full, by the milk expanding, a tap at the top of the mediator is turned and the whole is thus hermetically closed. The water in the boiler is then raised "to an intense heat, and this will keep the milk for another 50 minutes at a somewhat high temperature." The jars are next deposited upside down in a cooler, and left in this position for 60—80 minutes. This ensures the mixing of the milk, as it is in the nature of the milk that its fatty particles, and therefore the butter milk, will rise to the surface. The cans are finally placed in an upright position. The vacuum above the milk in the mediator is caused by the contraction of the milk. The air-tight stopper between the can or mediator is now turned, and as the ordinary temperature is rather higher, the can will be full, and there is little chance of the fat coagulating should the cans be shaken. The mediator is opened, and the milk in it having been run off, it is taken off and the process is complete. The milk is said not to lose its freshness, pureness, and sweetness even after 18 months or two years in hot countries, and when opened tastes like new milk, fresh and sweet.—F. W. T. K.

*Improved Apparatus for and Method of Purifying and Preserving Milk.* J. T. Appleberg, Knoxville, Tennessee, U.S.A. Eng. Pat. 1328, January 25, 1890. 8d.

THE apparatus consists of a box with hinged cover or lid and a hinged side. These can be closed air-tight. There is a central aperture in the lid which admits of the insertion

of a thermometer. The closed bottom of the box is provided with a grating or support on which rests a steam coil. As many of these boxes as may be found convenient may be connected with each other, either side by side, in tiers, or otherwise. The fresh milk, after straining, is poured into cans of the usual shape and construction. The lid of a can having been removed it is placed on the coil in a box and the lid and door of the box closed. The thermometer or indicator is then inserted through the aperture in the lid with its bulb projecting into the milk. Steam is then admitted into the coil and the temperature raised to 160° F. This initial heating is carried out rapidly so as to prevent separation of the milk. The temperature is then raised slowly to 185° or 190° F. (never to the boiling point). After the cans with their contents have been subjected to this treatment for a sufficient length of time, the steam is turned off, and the cans withdrawn and closed, after which they are ready (when cooled off sufficiently) for shipment and sale. The temperature of 185°—190° is sufficiently high to sterilise the milk, cans, and lids.—F. W. T. K.

*Improvements in the Manufacture of Butter and in Apparatus therefor.* F. R. C. Strüver, Pine Creek, Queensland. Eng. Pat. 1428, January 27, 1890. 8d.

THE cream from which the butter is to be made is enclosed in a bag made of a sheet or sheets of moleskin or other material which will allow of the escape of the butter milk but not of the cream. The mouth of the bag so formed is held tightly closed by means of a metal clasp or ring, specially devised for the purpose. When a number of these bags is ready, each is placed between suitably perforated plates (one above the other) enclosed in a perforated cylinder, and subjected to pressure for from 15 to 30 hours, according to the ripeness of the cream, by placing a heavy weight on the top of the whole.

The butter obtained is finally worked up by means of a butter-worker, the main portions of which are a cylinder, having inwardly projecting bars, and a central hollow spindle having radiating bars which can be made to revolve between the former. The butter-worker or the perforated cylinder which holds the bag is introduced into a vessel or cylinder which is covered with damask or other woollen material. This is kept damp and by the evaporation of the moisture the temperature of the whole apparatus is kept comparatively low. A low temperature is essential.

—F. W. T. K.

*Improvements in Apparatus for making Butter.* H. H. Lake, London. From C. H. F. Wilhelm Ove Ramel, Veile, Denmark. Eng. Pat. 2561, February 17, 1890. 6d.

TWO square frames, the corners of each of which are connected with each other by diagonal arms, serve as supports for eight vertical axes which are provided with beaters and which are set in motion by a tooth gearing, worked from a vertical central shaft, the central part of each frame forming a bearing for this shaft. Four vertical partitions in the apparatus serve to break the current of the milk. The whole is made of Britannia metal or some other suitable material, and is enclosed in a receptacle of sheet-metal provided a short distance from its bottom with a cock through which the butter milk is let out. With this apparatus the cream can be separated from the milk in about half a minute, and butter can be obtained in three minutes more.—F. W. T. K.

### (B.)—SANITARY CHEMISTRY.

*Recent Experiments on the Removal of Bacteria from Drinking Water by Continuous Filtration through Sand.* W. T. Sedgwick. Technology Quart. 3, 69—75.

THE present paper deals with the results of Dr. Fraenkel's investigations published in the *Deutsche Med. Wochenschr.* Dec. 12, 1889. The experimental filter beds consisted of barrel-shaped wooden tanks two metres high and 0.75 m. in average diameter, having at the bottom a sieve-like perforated support. This was filled precisely like the tanks

in actual use, *viz.*, with 150 mm. of stones of the size of the fist, 80 mm. of coarse gravel, 100 mm. of fine gravel and 600 mm. of finer sand. The surface was thus 1 m. below the top of the tank and was provided with an overflow. Special means were provided for avoiding sudden changes in pressure, so that the flow was perfectly regular and under control. Experiments were first begun with *Bacillus violaceus*, a harmless bacterium. It was cultivated in a very weak solution (1 part of ordinary bouillon in 20 parts of distilled water). Small doses of this fluid were added to the unfiltered water from time to time and usually at regular intervals of six hours. The supernatant water was then stirred in order to secure an even distribution of the bacillus all over the top of the tank. Samples of the water standing on the surface of the sand as well as of the effluent were examined bacteriologically every day from June 1st to the end of July. The results established the fact that, contrary to the prevailing opinion, the Berlin continuous sand filters are by no means germ-tight. The least efficient periods are those in which the filters are "young," *i.e.*, not yet covered on the top with a layer of organic material accumulated from the water previously passed through, or on the other hand "old," *i.e.*, so covered with organic matter that water passes through only under the compulsion of high pressure. It was observed that after prolonged running the number passed out increased somewhat even under no marked increase of pressure, and Fraenkel suggests that possibly some other cause than mere pressure is at work in such cases; such, for example, as the effect of the steady accumulation of food material within the tank, giving support finally to an undue number of bacteria in the lower layers. It appears that the number of germs in the effluent is directly dependent on the number in the unfiltered water. Moreover, the rate of flow seemed to be of the utmost significance. The filter which was run at the higher speed always showed the more bacteria, and, indeed, so uniformly that Fraenkel declares the results proportional. He lays down the rule that the qualitative efficiency of a continuous filter is inversely proportional to its quantitative efficiency. From the end of July to the middle of October Dr. Fraenkel experimented with the same filters as before, now using pathogenic germs. The results showed that the germ of cholera and typhoid may also pass through the sand filters. He points out, however, that the reduction in the number of germs by an effectively working and intelligently operated sand filter is astonishing; but any such system as is necessary for a large city requires the most skilful and intelligent supervision if the results are to be of the best. The rate of filtration is also, obviously, extremely important, and requires constant attention. If it be allowed that the germs may multiply in the filter, or that they are hardy—as increasing evidence seems to be indicating in the case of typhoid fever—the way is at once open for filters to become breeding places as well as passages for germs. For sewage disposal, continuous filtration fails utterly, since there is no free oxygen in sewage, and hence, no nitrification or other purification except the purely mechanical effect of the straining out of suspended matters, which lead to speedy stoppage of the filter. In drinking-waters there is an abundance of free oxygen, so that continuous filtration might, theoretically, allow the complete nitrification of the suspended matter mechanically held back. That this does not take place is probably due partly to the fact that the arrival of fresh material for oxidation takes place more rapidly than its removal by nitrification, and partly because nitrification appears to require a more or less prolonged contact between bacteria and the substances to be oxidised. It appears, therefore, that in the case of drinking water rich in oxygen, as well as of sewage destitute of oxygen, the process of continuous filtration is effective chiefly in the removal of suspended matters, and of these the finest particles (bacteria) are imperfectly separated. Intermittent filtration, on the other hand, readily effects the nitrification of the organic matters in sewage, by allowing the entrance of oxygen into the sand between the flooding periods and the purification of drinking-water by similar oxidation of the matters mechanically held back.—J. B. C.

*Experiments on the Efficacy of Filtration through Sand.*  
C. Fränkel and C. Piefke. *Zeits. für Hygiene*, 8, 1890, 1; and *Proc. Inst. Civil Eng.* 1890, 37—40.

IN the early months of 1889, Berlin was visited by an epidemic of typhoid fever which extended over a wide area, and which, from the middle of January to the middle of April, caused some seven hundred cases to come under the notice of the authorities. By reference to a map it is shown that this outbreak must have been wholly unconnected with the levels of the sub-soil water, as in lieu of extending over a district parallel with the course of the river, which would follow the lowest levels of the sub-soil water, it took a direction exactly the opposite, and attacked the western portions of the town, leaving the east end of Berlin untouched. For this reason the water-supply became suspected, and Virchow, at the meeting of the Berlin Medical Society on the 19th June, pointed to this as a possible cause of the epidemic. The authors mention several matters which may have contributed to the evil. The waterworks near the Stralau Gate possesses eight open and three covered filtering-beds. During the long-continued frosts of the winter months the open basins become frozen over, and in time become useless, so that the whole of the effective filtration has to be carried out in the three covered basins, which in consequence are worked at far too great a pressure. Thus, in February last, a rise in working speed took place of from 130 millimetres to 160 millimetres per hour, and on the 12th of March the maximum rate of filtration of 224 millimetres per hour was attained. The formation of a layer of bacteria on the surface of the sand is found to greatly retard the rate of filtration, and when the head of water is increased, it tends to drive the micro-organisms through the pores of the filtering material, and ultimately into the filtered water. This state of things is, of course, attained all the more quickly when the water to be filtered is very impure. By reference to a graphic diagram, the numbers of germs present per cubic centimetre of filtered water during the period in question are indicated. These rose rapidly from about one hundred in the middle of January to over ten times the amount in February, and attained, during March, the enormous total of upwards of four thousand per cubic centimetre. At the beginning of April, when the whole of the filter-beds were again in operation, the numbers of germs at once sank to the normal level. During these months the waters of the Spree were highly charged with bacteria, the numbers of germs, from January to March, often exceeding one hundred thousand per cubic centimetre. Though the presence of typhoid germs has not been demonstrated therein, the water supply of Berlin was manifestly extremely impure.

Much suspicion was expressed respecting this state of things, and the authors were commissioned by Dr. Koeh to investigate whether it might be possible to spread the germs of infectious diseases through the mains of the water company. For this purpose they undertook a series of experiments, all the necessary assistance being given to them by the company. It has hitherto been assumed by experts that the sand filter, carefully and properly managed, yields a germ-free, hygienically perfect filtrate. If this theory were thoroughly sound, investigations of the character of those here recorded would have been useless, but it soon became evident that complete experiments touching the fate of pathogenic micro-organisms passing through the sand filter had not hitherto been attempted. It was decided to employ small sections of the actual filter-beds, the apparatus being explained by reference to a diagram. Two tubs were used, each 2.1 metres (6.7 ft.) high and 0.75 metre (2.5 ft.) in mean diameter, at the base of which was a sieve-like collecting channel. The filtering material was disposed in these tubs in the same thicknesses as in the actual sections of the beds; *viz.*, 100 millimetres (3.9 in.) of pebbles of the size of hazel-nuts, 80 millimetres (3.1 in.) of coarse gravel, 100 millimetres (3.9 in.) of fine gravel, and 600 millimetres (2 ft. nearly) of fine sand. The surface of this sand was about 1.2 metre (4 ft.) below the top of the vessel, which was provided with an overflow-pipe.

The outlet-pipe from the filters was curved upwards to above the level of the sand, and the inlet-pipe was adjusted

to supply the water at any given rate. It was thus possible to work the filters at the required speed, and to avoid all disturbance of the contents. Having completed all these preparations, and formed two distinct filters, the authors were enabled to commence their observations, and they deemed it advisable to study, in the first instance, the behaviour of a bacillus of a non-dangerous character and of strongly marked features, and for this purpose the *bacillus violaceus* was selected. It was cultivated in very dilute nutritive bouillon, so as to render it impossible for the bacteria, when they were exposed to the still further dilution in the filter, to find the requisite supplies of food-stuff. This liquid, which had a pale bluish tint, was added every six hours to the contents of the unfiltered-water reservoir, in quantities of about 100 cubic centimetres at a time. Samples were taken daily for bacteriological examination, both of the unfiltered and of the filtered liquids, and they were cultivated on gelatin plates in the usual way. The filters were worked, the one at the rate of 300 millimetres (11·8 in.), the other at the rate of 100 millimetres per hour. The results are set forth in tabulated form, and prove that, throughout the whole period of observation, the bacteria passed through the filter, the numbers being in general accordance with the rate of filtration. About three times as many colonies were formed in the former filtrate as there were in the latter. When the speed of filtration was reduced in the second filter to 50 millimetres per hour, the relative abundance of the colonies of blue bacteria was about as 6 to 1. The proportion of the blue bacteria in the unfiltered water to those in the filtrate was, roughly speaking, 1,000 to 1. The slower rate of filtration produced, unquestionably, the better results. Similar experiments with cholera and typhoid fever bacteria gave corresponding results, which are set forth in tables, and the authors conclude that the sand filter is not a germ-proof apparatus, and is incapable of retaining the spores of the ordinary water-bacteria, as also those of a pathogenic character. The numbers of germs passing through the filter are in proportion to those in the unfiltered liquid, and in accordance with the speed of filtration. Both at the beginning and at the end of each periodic use of the filter, there is an interval of danger when the germs pass through the beds in greater abundance (see this Journal, 1889, 998).

*On the Passage of the Spores of Fungi and of Bacteria through Cloth used for Air-Filters.* K. Möller. Zeits. für Hygiene, 7, 1889, 379; Proc. Inst. Civil Eng. 1890, 40.

The author combats the conclusions of Dr. Petri on the above subject, and, as a member of the firm engaged in the production of air-filters, and as the first who undertook to filter air upon a commercial scale for industrial purposes, he points out certain mis-statements and erroneous deductions.

Air-filters are of two kinds; and for "germ-proof filters" he employs an ante-filter and ten layers of a specially thick, closely woven, and very much roughened material; for "dust-proof filters," only one thickness of a much less closely-woven fabric is used. Filters of the latter kind, though capable of excluding very large proportions of germs, are obviously not germ-proof. By the author's arrangement of the filter in the form of a series of pockets, the cloth moreover is used in a direction very oblique to the air-current, forming an angle with it of from 3° to 5°, whereas Dr. Petri tested the cloth at right angles to the air-current. By reference to enlarged sections of the fabric, the vast difference in the degree of permeability due to this change in the direction of the movement of germs is explained. It is shown also that Dr. Petri considerably strained the filter-cloth by subjecting it to the passage of abnormal volumes of air. Moreover, the author asserts that a woolly surface is one capable of entangling large numbers of germs, and that Dr. Petri actually neglected the obvious precaution of sterilising his cloth before the commencement of his experiments. He thus, doubtless, was led to regard a vast number of germs as having passed through the cloth, which, as a matter of fact, had been simply blown off its surface

by the air-current. The experiments of Dr. Petri are discussed in detail, and certain of them, for various reasons, are shown to be untrustworthy.

*On the Disinfection of Latrines by means of Lime.* E. Pfuhl. Zeits. für Hygiene, 7, 1889, 363; Proc. Inst. Civil Eng. 1890, 41.

HAVING by previous experiments demonstrated that the excreta of typhoid and cholera patients could be disinfected by means of relatively small quantities of milk of lime, the author resolved to investigate further whether the experience gained in the laboratory could be used in actual practice for the disinfection of fecal matters in tubs, cesspools, and night-stools. Lime can be procured on a commercial scale in such a pure state, as only to contain 1 per cent. of foreign matters, as has been found in the case of Wiesbaden, where from 2,000 to 3,000 kilogrammes of lime are used every 24 hours for the treatment of the sewage-water. The precautions to be taken in slacking and preparing the milk of lime are described. It is advisable to use double the quantity of water theoretically needed, viz., 60 parts of water to 100 parts of quicklime. It may be assumed with sufficient accuracy that 1 litre of slaked lime weighs  $\frac{1}{2}$  kilogramme; and in preparing a mixture of lime for use as a disinfectant, 1 litre of slaked lime is to be mixed with 4 litres of water. To test the action of the lime on the fecal matters, the author advocates the use of red litmus paper, coloured blue to various shades by solutions of lime of different known strengths. For cesspool-matters, as the result of a series of experiments on a cesspit of large size, details of which are given, as also full particulars of trials carried out on tubs used daily by soldiers in a barracks, the author recommends the use of from 1 to 1½ litre of slaked lime to each 100 litres of excreta contributed daily. The larger quantity being that advocated for tubs or pails. As the results of actual measurement, the daily increment of cesspool contents was found to be 400 cubic centimetres per head. The disinfection can best be effected when carried out daily. No reliance can be placed on any hand-mixing of the excreta with the lime. There is, therefore, no other course than to depend upon automatic admixture, or to arrange for some system of mechanical stirring of the cesspool contents, such as is accomplished by the apparatus of Thiriart, which is described.

(C)—DISINFECTANTS.

*The Action of Hydrogen Peroxide upon Infusoria.* J. Paneth. Chem. Centr. 1890, 174; and Proc. Inst. Civil Eng. 1890, 43.

THE infusoria with which these experiments were made were produced by inoculating a hay infusion with stagnant water and mud. The liquid thus obtained contained at least six different varieties of infusoria. The hydrogen peroxide was used in the form of a carefully neutralised solution of known strength. When the solution contained one part of hydrogen peroxide in 10,000 parts of water all ciliate infusoria were invariably killed in one quarter to half an hour. With a dilution of one in 20,000, parts of the organisms were destroyed, but some survived. The hydrogen peroxide was decomposed, either through the substances dissolved in the infusion or more probably by a catalytic action of the organisms. Hydrogen peroxide is therefore a violent poison for some forms of animal protoplasm. The author concludes from his experiments that the oxidising effect of such infusoria cannot be due to the presence of hydrogen peroxide in their cells, and from other experiments he is of opinion that they do not contain active oxygen to any considerable amount.

*The Disinfecting Action of Chloride of Lime.* F. Nissen. Zeits. für Hygiene, 8, 1890, 62; and Proc. Inst. Civil Eng. 1890, 42.

THE first bacteriological tests of the action of chloride of lime were given in Koch's work "On Disinfection," and it was shown therein that anthrax spores, dried on to silk

threads, were destroyed by a five days' exposure to the action of a 5 per cent. solution of the salt. Subsequently Sternberg and Jaeger have published the results of observations which differ in certain indicated particulars from those of Koch, and it therefore appeared advisable to undertake a fresh inquiry, which the author has carried out under the guidance of Dr. Koch. Samples of chloride of lime were procured from various dealers, and in all cases the material used was taken from the bottom of the jar or cask. The disinfecting action was tested by exposing the bacilli of typhoid fever, Asiatic cholera, anthrax, and two other species, immersed in alkaline bouillon, containing 1 per cent. of peptone and 0.5 per cent. of common salt, to equal volumes of the solution of chloride of lime. The liquids were well shaken, and samples, withdrawn after the lapse of 1, 5, 10, 15, and 20 minutes, and at longer intervals, were submitted to cultivation. The results of the observations are set forth in a series of tables, as also those of a further set of experiments directed to test the deadening powers, as respects the development of micro-organisms, of the chloride solution. In this latter respect, the influence of calcium chloride is insignificant. A third series of experiments was carried out with polluted liquids and human excreta, and from these it was ascertained that a 5 per cent. solution was capable of destroying the germs present in diarrhetic faeces within less than 10 minutes. From the first set of tests it was shown that the bacilli of cholera, typhoid fever, and anthrax\* were destroyed by a solution containing not less than 0.12 per cent. of chloride of lime in one minute. The germs of *staphylococcus* and *streptococcus* were rendered incapable of further development by exposure for one minute to a 0.2 per cent. solution of the chloride in bouillon.

#### PATENTS.

*Improvements in the Manufacture or Preparation of Disinfectants or Antiseptics.* W. Black, Newcastle, and W. L. Rennoldson, Jarrow. Eng. Pat. 8527, May 22, 1889. 4d.

In a previous patent (Eng. Pat. 1969, of 1888; this Journal, 1889, 131) the manufacture of antiseptics is described, wherein perchloride of mercury is incorporated with glauber salt or equivalent absorbing salt. The efficiency of the disinfectant or antiseptic is now further enhanced by the further incorporation of free sulphuric or hydrochloric acid, which makes the action of the perchloride more energetic, as well as of eucalyptus oil or thymol or some similar disinfecting oil or essence. The proportions preferred are: Perchloride of mercury four parts by weight, sulphuric or hydrochloric acid four parts, eucalyptus oil (or its equivalent) one part, indigo (or its equivalent) one part, and glauber's salt (sulphate of soda), either anhydrous or crystallised, or both together, 90 parts, by weight respectively. The colouring matter is merely added for the sake of convenience, as it is an advantage in practice to have the material or its solution of a distinct colour. The disinfectant is manufactured in the form of a liquid or solution or in a dry state, and made up, if so desired, in impervious packets containing any proper quantities for use.

—F. W. T. K.

*A New Method of Producing and Liberating Aërial or Gaseous Disinfectants.* G. T. Moody, F. W. Streetfield, London. Eng. Pat. 19,309, December 2, 1889. 4d.

This invention consists in the production of free haloids for disinfection, inhalation, and similar purposes by incorporating a certain quantity of the haloid compound with a convenient medium such as paraffin, wax, fats, oils, and other combustible substances, and making candles, tapers, night lights,

matches, or pastilles out of the mixture or using it in lamps. Iodoform, bromonaphthalene, and chloronaphthalene are stable and give very satisfactory results, but the patentees do not restrict themselves to the use of these halogen compounds. On combustion a considerable portion of the halogen is liberated in the free state. For general hygienic purposes combustible material containing a quantity of haloid compound equal to 1 or 2 per cent. of the free haloid is employed. The amount of halogen evolved can be regulated with great exactness by dissolving a known weight of the halogen compound in the combustible and by burning the candle, &c. for a definite time.—F. W. T. K.

*Improvements in Toilet or Sanitary Paper.* R. Hannan, Glasgow. Eng. Pat. 19,638, December 6, 1889. 4d.

To ensure the sanitary treatment of drains, closets, &c., the toilet paper is impregnated with antiseptic substances which have no injurious effect on the human body. Any ordinary variety of soluble antiseptic matter may be employed, such as carbolate of soda, sulphate of zinc, and the like. A mixture of boracic acid with borax to which a small proportion (say one-fortieth of its weight) of salicylate of sodium or other soluble salicylate has been added, is preferred. The liquid or dissolved antiseptic is either added to the pulp, or the finished tissue paper is run through a trough containing the solution, or is passed through a spray of the antiseptic and then dried.—F. W. T. K.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Synthesis of Alcohol Acids of the Pyridine Series.*

A. Einhorn. Ber. 23, 219—224.

SINCE cocaine has been found to be a derivative of  $\alpha$ -pyridyl- $\beta$ -lactic acid, the author has paid particular attention to the condensation product prepared from  $\alpha$ -picoline and chloral, which was discovered by him in conjunction with A. Liebrecht (Ber. 20, 1592).

The following bodies were obtained from  $\omega$ -trichlor- $\alpha$ -hydroxypropylpyridine as raw material. By treatment with phosphorus pentachloride the corresponding hydrocarbon pyridyl- $\omega$ -trichlorpropylene,  $C_5H_4CH:CH.CCl_3$ , was produced with elimination of water, forming prismatic needles, melting at 97°. By means of a boiling solution of caustic soda the raw material was converted into pyridyl- $\alpha$ -lactic acid,  $C_5H_4N.CH_2.CHOH.CO_2H$ , and thereby converting the group  $CCl_3$  into  $COOH$ . A particularly characteristic copper salt of the acid was prepared. The free pyridyl- $\alpha$ -lactic acid, which represents the carbon acid of  $\alpha$ -picolyl-alkine of Ladenburg (Ber. 22, 2584; this Journal, 1890, 100), and crystallises from alcohol in transparent prisms, melting between 202°—204° C. Methyl and ethyl ethers, as well as platinum and gold double salts of the were acid, obtained.

Pyridylacrylic acid (m.p. 202°—203° C.) resulted from the treatment with alcoholic potash, which does not only eliminate the chlorine from the  $\omega$ -trichlor- $\alpha$ -hydroxypropylpyridine, but at the same time splits off water and also forms some pyridyl- $\alpha$ -lactic acid. A number of ethers and double compounds of this acid were also prepared.

Pyridyl- $\beta$ -lactic acid,  $C_5H_4N.CH_2.CHOH.CO_2H$ . This acid is obtained along with pyridine-ethylene,  $C_5H_4N$ , (Ladenburg's vinylpyridine, Ber. 22, 2583; this Journal, 1890, 99), and undecomposed pyridyl-acrylic acid, by heating the latter compound with anhydrous acetic acid in a sealed tube to 100° C. The hydrobromide of pyridyl- $\beta$ -bromopropionic acid, which thus results, is carefully

\* In a note appended by the author he states that some anthrax spores recently received, with such high powers of endurance as to be capable of resisting a four hours' exposure to a 0.1 per cent. solution of corrosive sublimate had succumbed in 4½ hours to a 5 per cent. solution of chloride of lime.

decomposed by soda, yielding above bodies. The free pyridyl- $\beta$ -lactic acid is extremely soluble in water, and forms a beautiful copper salt, the hydrochloride crystallises from alcohol in white prisms, melting at  $145^{\circ}$ — $146^{\circ}$  C.

Pyridylglyceric acid,  $C_5H_5N \cdot CHOH \cdot COOH$ , is formed by oxidation of the sodium salt of the acrylic compound

with potassium permanganate; the hydrochloride, which contains one molecule of water of crystallisation, melts at  $189^{\circ}$ — $190^{\circ}$  C.

The importance of the relation which exists between cocaine and its compounds and the bodies prepared by the author may be seen from the following table:—

Anhydro-cocaine.

Ecgonine.

Benzoyl-ecgonine.

Cocaine.

Pyridylacrylic acid.

Pyridyl- $\beta$ -lactic acid.Benzoyl-pyridyl- $\beta$ -lactic acid.Benzoyl-pyridyl- $\beta$ -lactic methylate.

—O. J. S.

On *Apiol*. J. Ginsberg. Ber. 23, 323—325.

REFERRING to previous investigations on the subject (Ber. 21, 2516; this Journal, 1888, 399 and 583; 1889, 1007), author gives further particulars of an acid obtained by the action of sulphuric acid and manganese dioxide on iso-apiol, to which he gave the name *aponic acid*.

The yield of the acid being a very bad one, author, after trying various methods, found the following to be the best. A mixture of 240 grms. of water, 60 grms. of sulphuric acid, and 6 grms. of iso-apiol are brought to the boil, and 60 grms. of commercial manganese dioxide gradually added, and boiling continued for four hours. On extraction with ether, evaporation of the latter, conversion into ammonium salt and decomposition with hydrochloric acid, the free acid is obtained from water in small colourless needles, melting at  $252^{\circ}$  without decomposition. Apiol treated in the same manner does not yield an oxidation product. From the formula obtained,  $C_{14}H_{10}O_3$ , aponic acid might be identical with one of the oxybenzoic acids, which however is not the case, the formula, therefore, may also be  $C_{14}O_{12}O_6$  or  $C_{14}H_{10}O_6$ .

Iso-apiol tested after Zeisel's test proved to contain two  $(OCH_3)$  groups, whereas aponic acid does not contain any. Aponic acid is an extremely stable compound, which is not acted upon by hydrochloric or bromic acid under pressure,

and is not even attacked by a mixture of nitric and sulphuric acid. Phenylhydrazine nor hydroxylamine do form a condensation product with the acid. The calcium, silver, and barium salts were also prepared, the latter for instance having the formula  $C_{14}H_{10}O_6Ba$  or  $C_{14}H_8O_6Ba$ . The silver salt and ethyl iodide yielded an ethyl ether.—O. J. S.

Some Derivatives of *Cantharidine*. F. Anderlini.

Ber. 23, 485—486.

THE author, after mentioning work which had been done by Piccard and Homolka in order to throw some light upon the constitution of cantharidine, describes some investigations made by him in that direction.

His attempts to oxidise cantharidine by means of fuming nitric acid, were not successful, as he could not obtain the product free from undecomposed cantharidine. According to experiments made by Homolka (Ber. 19, 1082) it was to be foreseen that cantharidine would enter into a combination with phenylhydrazine, which was confirmed by author. On heating 1 part of cantharidine with 4 parts of phenylhydrazine and 2 parts of acetic acid (50 per cent.) to  $130^{\circ}$ — $140^{\circ}$  C. two bodies were obtained, which were separated by crystallisation from benzene. The more

soluble part which was purified by recrystallisation from alcohol melts at  $237^{\circ}$ — $238^{\circ}$  C. and is cantharidphenylhydrazine ( $C_{16}H_{12}O_4 \cdot C_6H_5N_2H$ ). The second compound melts at  $130^{\circ}$ — $131^{\circ}$  C. and has the formula  $C_{16}H_{21}N_4O_2$ . On heating cantharidine with 10 parts of strong alcoholic solution of ammonia in a sealed tube for eight hours small prisms were obtained which gave figures corresponding to the formula  $C_{10}H_{12}(NH)O_2$ , melting at  $200^{\circ}$ — $201^{\circ}$  C. In this compound one of the oxygen atoms of cantharidine is substituted by an imido group.—O. J. S.

*Catalytic Formation of Ammonia from Nitrates.* O. Loew. Ber. **23**, 675—680.

See under XV., page 634.

*$\gamma$ -Coniceine, Conyrrine, and Inactive Coniine.* E. Lellmann and W. C. Müller. Ber. **23**, 680—684.

THE authors have confirmed the identity of the substance coniceine obtained by the action of alcoholic potash on coniine chlorinated at the nitrogen atom (this Journal, 1889, 636) with the base obtained by Hofmann by the action of bromine and sodium hydrate on coniine, and called  $\gamma$ -coniceine. Pure coniceine is optically inactive. The constitutional formula for this body previously proposed by the authors, viz. :—

Coniceine.

is confirmed, for by distillation of its zinc double chloride with zinc dust it is completely converted into  $\alpha$ -propylpyridine, the identity of which was established by an analysis of its platinum double chloride. This salt was found to melt at  $172^{\circ}$ , whilst Ladenburg gives  $159^{\circ}$ — $160^{\circ}$  as its melting point. The crystalline form of the two preparations agreed, and by distilling coniine hydrochloride with zinc dust and converting the propyl-pyridine obtained into the double platinum chloride, this was also found to melt at  $172^{\circ}$ . It appears therefore that two distinct modifications of this salt exist. Some  $\gamma$ -coniceine seems to be formed together with conyrrine when coniine hydrochloride is distilled with zinc dust. Tin and hydrochloric acid reduce coniceine to coniine—a further confirmation of the above formula. The product obtained, like Ladenburg's synthetically-prepared coniine, was inactive.—C. A. K.

*New Method for Preparing Ethylsulphonic Acid.*

F. Mayer. Ber. **23**, 908—912.

THE author has found that on heating concentrated solutions containing molecular proportions of sodium sulphite and sodium ethylsulphate from  $110^{\circ}$ — $120^{\circ}$  in a closed vessel, sodium ethylsulphonate is obtained according to the equation :—

For the purpose of identifying the acid obtained in this manner the following salts were prepared and examined :—

The sodium salt  $C_2H_5SO_3Na + H_2O$  forms small lamellar crystals, which lose water on heating. The double salt  $4 C_2H_5SO_3Na \cdot Na_2H_2O$  was obtained by dissolving two parts of anhydrous sodium ethylsulphonate and one part of sodium iodide in hot alcohol, 96° Tr. On cooling the mass crystallises in fine silky needles. Although this salt contains water it does not lose weight when heated to  $100^{\circ}$ , but decomposes at a higher temperature. The barium salt  $(C_2H_5SO_3)_2Ba + 2H_2O$  was prepared by decomposing the sodium salt with sulphuric acid, extracting the resulting ethylsulphonic acid with alcohol, saturating with barium carbonate, filtering, evaporating the filtrate to a small bulk,

and adding alcohol to the evaporated mass. On standing the barium salt crystallises out in the form of colourless lustrous needles. The chloride  $C_2H_5SO_3Cl$  was obtained by mixing the anhydrous sodium salt with phosphoric pentachloride, adding water and subjecting the resulting oily product to fractional distillation. It boils at  $171^{\circ}$ — $173^{\circ}$ .

—D. B.

*A By-product in the Synthetical Method of Preparation of Cocaine.* C. Liebermann and F. Giesel. Ber. **23**, 926—929.

IN a previous communication (this Journal, 1890, 543) the authors described a by-product obtained in the preparation of cocaine, which appeared closely allied to the dextrorotatory cocaine obtained by Einhorn and Marquardt (this Journal, 1890, 513). There were, however, some points of difference in the two products and their derivatives, and in order to establish the identity or otherwise of the two bodies the authors have prepared dextro-rotatory cocaine according to the directions of Einhorn and Marquardt, and compared its properties with the base obtained by themselves. The two bodies appear identical in every respect; both the bases were obtained in a crystalline condition, and the slight solubility of their nitrate in water, which had previously appeared to distinguish the two products, is characteristic of them both. The by-product is therefore isomeric with cocaine.—C. A. K.

*Preparation and Properties of Aricine.* H. Moissan and E. Landrin. Compt. Rend. **110**, 469—471.

THE authors have extracted 2 kilos. of the alkaloid aricine, first discovered by Pelletier and Coriol in the bark known as *Cusco cinchona*, or *arica* bark. The bark used by the authors contained neither quinine nor cinchonine, but from 3 to 3.5 per cent. of aricine, a much larger proportion than that recognised by previous experimenters. To extract it the powdered bark is mixed with 10 per cent. of lime and the same quantity of strong caustic soda, and the mixture nearly dried on a water-bath. The residue is repeatedly extracted with ether, and the ethereal solution precipitated by addition of sulphuric acid, when a cheesy yellow sulphate of aricine separates. This is dissolved in boiling water, and the crude alkaloid precipitated by ammonia as a resinous substance. This is powdered, and crystallised two or three times from boiling alcohol. Analysis leads to the formula  $(C_{23}H_{26}N_2O_4)$  which is that already adopted by Gerhardt. The pure alkaloid is insoluble in water, soluble in 90 per cent. alcohol (which dissolves 10 grms. per litre at  $15^{\circ}$  and 90 grms. at the boiling temperature), and soluble in ether (30 grms. per litre at  $15^{\circ}$ ); it melts at  $188^{\circ}$ — $189^{\circ}$ . The rotatory power in alcoholic solution is  $[\alpha]_D = -58^{\circ} 18'$  and in ethereal solution  $[\alpha]_D = -92^{\circ} 30'$ . The hydrochloride in alcoholic solution has a rotatory power of  $[\alpha]_D = +14^{\circ} 30'$ . The melting point and optical properties thus differentiate the alkaloid from its isomer *cusconine*.—J. M. H. M.

*Fluoroform.* Meslans. Compt. Rend. **110**, 717—719.

IODOFORM (2 parts), silver fluoride (2 parts), and chloroform (1 part) are mixed in a flask kept well cooled by iced water and connected with a lead worm (cooled down to  $-23^{\circ}$ ) leading to a U-tube containing dry silver fluoride heated to  $100^{\circ}$ . When the temperature of the water around the flask is slightly raised a colourless gas is steadily evolved and may be collected in glass jars over mercury. It is freed from chloroform by prolonged contact with dry caoutchouc, and from a trace of carbon monoxide by cuprous chloride. Fluoroform has an agreeable odour resembling chloroform; it burns with some difficulty, forming hydrogen fluoride, and imparting a blue colour to the flame. It is sparingly soluble in water, chloroform, and benzene, but dissolves in about one-fifth its volume of alcohol.

It may be liquefied by a pressure of 40 atmospheres at  $20^{\circ}$ , and if more strongly compressed and released, it solidifies. When heated in a sealed tube with alcoholic potash, it is decomposed into potassium fluoride and formate.

Sodium burns with brilliancy when heated in this gas, carbon, sodium fluoride, and methane being formed.

The action of dry silver fluoride on iodoform containing no admixture of chloroform gives rise to a gaseous fluoriodoform which is now under investigation.—S. B. A. A.

#### *Sulpho-conjugated Phenols derived from Camphor.*

P. Cazenave. *Compt. Rend.* **110**, 719—722.

THE action of concentrated sulphuric acid on camphor is known to result in the formation of camphorone, but the simultaneous formation of sulphonic derivatives has hitherto been overlooked. When camphor is heated with concentrated sulphuric acid, the camphorone removed, and the largely diluted acid liquid saturated with barium carbonate and filtered, the solution is coloured faintly violet by ferric chloride, and yields on evaporation small quantities of a difficultly crystallisable barium salt of a sulphonic acid.

By heating camphor monochloride (100 grms.) with concentrated sulphuric acid (500 grms.) to 30°, a solid (A) and three liquid syrupy compounds (B, C, D) may be isolated, all of which dissolve in water, are inactive to light, give the phenol reactions with ferric salts and acetic anhydride, and contain sulphur in the sulphonic state, only removable by fusion with potash.

The formula found for (A) is  $C_9H_{12} \cdot SO_2 \cdot (OH)_2 \cdot O$ , both of the hydroxyls being alcoholic; for (B)—

for (C),  $C_{10}H_{14}(SO_2OH)_3 \cdot OH \cdot O_5$ . No formula has yet been determined for (D).

The author points out that the formation of these compounds is a proof that the terebene series contains the benzene nucleus.—S. B. A. A.

#### *Some Compounds of Chlorides of Mercury with Ammonia.*

G. André. *Bull. Soc. Chim.* 1889, **2**, 145—153. (See also this Journal, 1889, 915 and 916.)

WHEN the compound  $NH_2HgCl \cdot HgCl_2$  is heated to 130° in a vacuum, nitrogen is slowly evolved, and between 160° and 230° it is accompanied by ammonia. Beyond this temperature nitrogen is mainly given off. Mitscherlich succeeded at one stage in isolating the compound  $2 NH_2Cl$ .

The action of potash and dilute sulphuric on the compound  $NH_2HgCl \cdot HgCl_2$  decomposes it, and in both cases the same amount of nitrogen, in form of ammonia (4.3 per cent.), evolved. If treated with sulphuretted hydrogen all the nitrogen is evolved as ammonia. Potassium chloride dissolves the compound, and this solution may be readily analysed. It is treated with sulphuretted hydrogen, the mercury separated as sulphide, and the filtrate boiled with caustic alkali, and the ammonia collected and titrated. The chlorine may be determined by heating with lime to redness, or by dissolving the compound in ammonium sulphate, adding acetic acid, precipitating the mercury with sulphuretted hydrogen, and, after getting rid of the gas, titrating the chlorine.

Ammonium chloride dissolves the compound, forming an addition product  $NH_2HgCl + NH_4Cl = (NH_3)_2HgCl_2$ .

The chloramide is decomposed by boiling water, giving a compound  $NH_2(HgOHg)Cl$ , which dissolves in cold ammonium chloride, but not in a hot solution.

If the equivalent of potash is first added to mercuric chloride before the addition of ammonium chloride, the chloride of tetramerenammonium,  $NH_2Cl$ , forms part of the precipitate. On the other hand, ammonia has a tendency to react with mercuric chloride and to form the chloramide, which again is decomposed by water, forming  $NH_2(HgOHg)Cl$ . The precipitate may consist, therefore, of the three compounds,  $NH_2Cl$ ,  $NH_2HgCl$ , and  $NH_2(HgOHg)Cl$ . This result appears from the analyses, which do not correspond to any simple formula.

On adding ammonium chloride solution to freshly precipitated mercuric oxide, formed by adding caustic potash to mercuric chloride, the yellow tint of the oxide becomes paler, and, after two hours' shaking, the precipitate is perfectly colourless. The precipitate, when washed and

dried, contains three-fifths of the nitrogen of the ammonia salt. The following reaction may occur—

Whenever ammonium chloride is present with tetramerenammonium chloride, the former disappears according to the reaction  $NH_2Cl + NH_4Cl = 2 NH_3HgCl$ .

This being the case, and the chloramide undergoing decomposition with water forming dimerenammonium chloride, the formula of the precipitate may be represented as follows, which agrees with the analyses—

But if the ammonium chloride is first added, and subsequently the potash, then the light yellow precipitate remains unaltered, and the precipitate has the formula—

When less ammonium chloride is employed in the first reaction, it requires longer for the precipitate to become white, and only one quarter of the nitrogen is taken up. The precipitate corresponds to the formula—

If the reaction occurs at the boiling point of water, the compound  $NH_2Cl$ , being stable, and the chloramide being converted into dimerenammonium chloride, the product will consist of equal molecules of the bodies—

When ammonia is allowed to act upon a mixture of freshly precipitated mercuric oxide and chloride, the filtrate contains no nitrogen. The reaction takes place as follows:—

This compound of equal molecules of the two salts is very stable.

If a mixture of mercuric chloride, ammonia, and potash be made, the two former being in excess, the precipitate, which changes, on shaking, from yellow to white, takes up two-thirds of the nitrogen in the form of ammonium chloride. The compound appears to have the formula—

If the ammonia alone is in excess, the amount of mercury in the precipitate increases and the chloramide disappears. The formula here is  $NH_2HgCl + 2 NH_2(HgOHg)Cl$ .

When potash is added to the chloramide there is no change of colour in the precipitate. From the quantity of ammonia found in the filtrate, the following reaction probably occurs:—

—J. B. C.

#### *The Alkaloids of Cod Liver Oil.* A. Gautier and L. Mourgues. *Bull. Soc. Chim.* 1889, **2**, 213—238.

IN pursuance of the work of one of the authors on the prevalence of leucomaines in the animal economy, a research was begun on the question of the presence of alkaloidal bodies in cod-liver oil, and their therapeutic value. The oils to which most attention was paid were the light brown samples which are generally admitted to be the most active. Such oils are not obtained by extraction from the perfectly fresh livers, but are produced after a certain fermentative change, distinct from putrefaction, has taken place which causes them to contain biliary products. The sample worked upon came from Bergen, and its purity was assumed from the evidence afforded by its direct origin, its specific gravity (0.928 at 15° C.), its rise of temperature with sulphuric acid (89.3° C.), and by its remaining fluid at 0° C. After many experiments and the qualitative proof of the presence of alkaloids, the following plan was adopted for their extraction: 100 kilos. of the oil were extracted with an equal volume of 35 per cent. alcohol containing 3 grms. of oxalic acid per litre, by shaking in 20 bottles of a capacity of 15 litres each. Oxidation was prevented by replacing the air by carbon dioxide. The extract was

nearly neutralised with milk of lime, filtered, and distilled *in vacuo* at 40° C. When the bulk of the solution had been reduced to one-twentieth, lime was added to complete neutrality and the evaporation finished *in vacuo*. The residue was treated with 83 per cent. alcohol, the solution filtered, distilled *in vacuo*, potash added to the residue and the bases thus freed shaken out with ether. From their ethereal solution they were precipitated by powdered oxalic acid, the oxalates washed with ether and dried. By this means 53 grms. of oxalates were obtained, and subsequent examination of the extracted oil showed it to be almost free from basic constituents. It appears, therefore, that the light brown oil contains as much as 0.5 gm. of mixed alkaloids per kilo., equivalent to about 6.5 mgrms. in a spoonful weighing 13.5 grms., whereas the almost colourless specimens gave no ponderable quantity when as much as 10 kilos. were treated. From 52 grms. of the crude oxalates 26.5 grms. of free dried alkaloids were obtained. By fractional distillation and crystallisation of the chloroplatinates, there were separated and identified:—

(1.) Butylamine, consisting chiefly of normal butylamine, but having its boiling point raised by the presence of a little amylamine. Its physiological action was tried on a young guinea-pig, 0.025 gm. being injected, producing stupor and increasing the secretion of urine.

(2.) Amylamine, found to be chiefly iso-amylamine, corresponding to fermentation amylalcohol. It was extremely poisonous, 4 mgrms. of the hydrochloride subcutaneously injected into a greenfinch causing death in three minutes; smaller doses increase the flow of urine.

(3.) Hexylamine, having a physiological action similar to, but weaker than that of amylamine.

(4.) *Dihydrolutidine*, a new base forming about one-ninth of the total quantity of alkaloids extracted from the oil, being obtained from the fraction boiling between 198° and 200° at 770 mm. Analysis gave the figures C = 77.31, H = 10.47, N = 12.52 parts per cent. respectively, instead of the theoretical values C = 77.07, H = 10.09, N = 12.84, which correspond to the formula  $C_7H_{11}N$ , lutidine being  $C_7H_9N$ . Its vapour density determined by Victor Meyer's method, using a bath of diphenylamine vapour, was 3.3 instead of 3.8. It is a colourless somewhat oily liquid, alkaline and caustic, with a pungent but not disagreeable odour. It absorbs carbon dioxide from the air and is slightly soluble in water. Its boiling point is 199° C. (corr.). The hydrochloride crystallises in ill-defined needles or plates, has a bitter taste, is very soluble in water though not deliquescent, and in aqueous solution is partially dissociated at 100° C. The nitrate reduces silver nitrate just as the dihydropyridines do (Hofmann). The sulphate is somewhat bitter, odorous, and deliquescent, and crystallises in needles arranged in stellate groups. The chloroplatinate is a canary-yellow salt crystallising in needles or lozenge-shaped plates, soluble in hot water, but sparingly in the cold; it loses hydrochloric acid when boiled with water. The double salt formed with gold chloride forms thin lozenge-shaped plates, or in needles disposed fan-wise. When dihydrolutidine is mixed with a slight excess of methyl iodide in the cold, a confused mass of crystals of methyl dihydrolutidine iodide separates out, from which weak potash liberates methyl dihydrolutidine, which is one of the dihydrocollidines already known. Unlike the products of the action of methyl iodide on most of the pyridine bases, methyl dihydrolutidine does not give a red colouration with strong hot caustic potash. From its behaviour on oxidation with potassium permanganate, and the nature of the products, the authors are of opinion that dihydrolutidine contains two side chains, and corresponds to the formula  $C_5H_3(11)(CH_2)_2NH$ , and may be regarded as a dimethyl dihydropyridine. Dihydrolutidine is fairly toxic; a dose of 0.07 gm. per kilo. first caused trembling and excitement, followed by depression and partial paralysis, when administered to a guinea-pig. Death commonly follows.

(5.) *Aselline*,  $C_{25}H_{22}N_4$ .—After the separation of the above-mentioned bases by distillation, a new fixed base, yielding a sparingly soluble chloroplatinate, is obtained as a greyish amorphous non-hygroscopic mass, becoming yellowish when exposed to air and light. It has a density

of 1.05, and fuses to a brown liquid with an odour recalling that of certain ptomaines. It is only slightly soluble in water (yielding an alkaline, slightly bitter solution, from which it is precipitated by potash), but is easily soluble in ether and alcohol. Concentrated sulphuric acid gives a faint red colouration, soon becoming brown. Its salts are partially dissociated by water, the base being precipitated. The hydrochloride crystallises in small confused crosses, and is rather bitter. It forms a double salt with gold chloride, sparingly soluble, and depositing metallic gold on heating its solution, a white one with mercuric chloride, and a yellow easily alterable compound with platinum chloride. Aselline constitutes about one-fifteenth of the total bases; with regard to its physiological action, a small dose produces stertorous breathing and stupor; a large one, convulsions and death.

(6.) *Morrhaine*,  $C_{19}H_{27}N_3$ .—The chloroplatinate of this new base is more soluble than that of aselline and is obtained after the removal of the latter. The base is a yellowish oily liquid with an odour of *Seringa flowers*. It is slightly soluble in water, freely soluble in alcohol and ether, strongly alkaline, and absorbs carbon dioxide from the air. It precipitates cupric salts but does not redissolve the precipitate. Its hydrochloride crystallises in needles forming stellate groupings and is very deliquescent; the double salt with gold chloride is easily reduced on heating its solution; that with mercuric chloride is soluble, while the chloroplatinate crystallises in feathery needles sometimes agglomerated with rounded masses. Its physiological action is of especial interest, inasmuch as it forms rather more than a third of the total bases, and thus any activity that it may possess would largely account for the therapeutic value of the oil. Its toxicity is slight but it is a powerful diuretic and sudorific. It greatly aids assimilation and increases the appetite. 29 mgrms. injected as hydrochloride into a guinea-pig weighing 235 grms. caused micturition no fewer than five times in 2 hours 12 minutes, the animal losing 12.5 grms. This corresponds to the passage of 3,872 grms. in the case of a man, the normal maximum being 1,400 grms. in two hours. Morrhaine then is the characteristic active constituent of cod-liver oil.

Besides these alkaloids there are found in the alcoholic extract from cod-liver oil several complex *lecithins* and other organic bodies containing phosphorus, which doubtless add to the medicinal properties of the oil by presenting that element in an easily assimilable form. In the original extraction of the oil by alcohol, certain acids are removed from it as well as the bases, and remain as potassium salts after the latter have been shaken out by ether in the scheme of extraction detailed above. They can be obtained by acidulation by sulphuric acid, and comprise formic and butyric acids, phosphoric and glycerin-phosphoric acids, and *morrhaine acid*, the most important in therapeutic effect. *Morrhaine acid*,  $C_7H_{13}NO_5$ , is probably contained in the oil in the form of lecithins or similar bodies, from which it separates on evaporating the acidulated alcoholic extract. When purified it crystallises in dirty yellow prisms or plates. It is slightly soluble in water, freely soluble in alcohol, and behaves both as an acid and base, combining with both alkalis and acids. It forms double salts with platinum and gold chlorides. From its behaviour on distillation with alkalis and oxidation with permanganate the authors believe it to contain the pyridine nucleus, and one carboxyl group united with that nucleus *indirectly*, and assign to it the formula—

The *Gadaine* of De Jongh seems to be identical with morrhaine acid, although stated by him to contain no nitrogen. The physiological action of morrhaine acid was found to be to increase the appetite and renal secretion. The latter property is particularly striking when a guinea-pig is used for experiment, as normally the urine of that animal is turbid and scanty, becoming clear and abundant after the administration of the dose.

Cod-liver oil may, therefore, be regarded as a vehicle and storehouse for quite a number of active principles tending to increase excretion and appetite, while presenting a certain quantity of food substances in a highly assimilable form.—B. B.

*On p-Hydroxyquinolinesulphonic Acid.* A. Claus and M. Posselt. J. prakt. Chem. **41**, 158—160. (See Monatsh. **10**, 804, and J. prakt. Chem. **41**, 41.)

THE authors describe briefly the above-named acid and its salts—*p*-hydroxyquinolinesulphonic acid—

In yellow needles decomposing at  $270^\circ$ , with difficulty soluble in water, soluble in alcohol, dilute hydrochloric acid and glacial acetic acid. Insoluble however, in ether, benzene, &c. The acid forms no dyes with diazo-compounds. It forms basic and normal salts of the alkalis. The normal sodium (1 mol.  $\text{H}_2\text{O}$ ) and potassium (1 mol.  $\text{H}_2\text{O}$ ) salts are described. A *mono-* and *di-bromo derivative* were obtained with 1 and 2 mols. respectively of bromine, both occur in needle-shaped crystals, the latter being insoluble in water but soluble in alcohol.—D. A. S.

*Action of Ammonium Formate on Ketones.* R. Leuckart. J. prakt. Chem. 1890, **41**, 330—340.

AROMATIC aldehydes and ketones, on heating with ammonium formate, are first reduced, owing to the liberation of carbon monoxide, and then converted into the corresponding base. Benzophenone, for example, gives benzhydramine,  $(\text{C}_6\text{H}_5)_2\text{CH.NH}_2$ , whilst acetophenone yields phenylethylamine,  $\text{C}_6\text{H}_5.\text{CH}(\text{CH}_3).\text{NH}_2$ . The reaction is in some cases rather complicated; benzaldehyde, for example, gives not only benzylamine, but also formylbenzylamine, dibenzylamine, formyldibenzylamine, and large quantities of tribenzylamine.

Benzil, phenanthraquinone, and benzoin, yield nitrogenous condensation products on heating with ammonium formate, whilst anthraquinone is simply reduced to anthracene.

Three bases are formed when acetone is heated with ammonium formate ( $1\frac{1}{2}$  parts) at  $200^\circ$ — $210^\circ$  for five hours. These compounds can be isolated as follows:—The crude product, which is a yellowish brown oil with a powerful coniine-like smell, is mixed with excess of soda and the bases distilled with steam; the distillate is acidified with hydrochloric acid, concentrated by evaporation, then rendered strongly alkaline with soda, the liberated bases extracted with ether, dried over caustic soda, and fractionated.

The fraction boiling at  $155^\circ$ — $156^\circ$ , which represents about 9 per cent. of the acetone employed, is a colourless strongly basic oil, with a slight alkaloid-like odour; it has the composition of a tetrahydrocollidine,  $\text{C}_{10}\text{H}_{15}\text{N}$ .

The fraction boiling at  $195^\circ$ — $200^\circ$  is a yellow strongly basic oil, with a very powerful disagreeable smell; it has the composition,  $\text{C}_{10}\text{H}_{15}\text{N}$ .

The fraction boiling at  $260^\circ$ — $270^\circ$  is also a yellowish-brown, strongly basic oil with a very powerful disagreeable smell; its composition is  $\text{C}_{10}\text{H}_{15}\text{N}$ .

These three compounds are probably members of a homologous series of bases nearly related to the pyridine bases or their reduction products; this is shown not only by their composition, but also by their strongly basic character, and their peculiar coniine-like smell, which properties they have in common with the coniceines  $\text{C}_8\text{H}_{13}\text{N}$ , para-coniine, triacetone, and other bases of like nature. Their method of formation also shows that the bases described above are probably pyridine derivatives, as such compounds can be obtained by the action of ammonia on acetone. The bases containing oxygen, for example, which are obtained by heating acetone, or a mixture of acetone and an aldehyde with ammonia, are hexahydropyridine derivatives, as has been shown by Heintz and E. Fischer, whilst from acetone and aldehyde ammonia, and from mesityl oxide and ammonia trimethylpyridine is obtained.

The boiling point of the base  $\text{C}_{10}\text{H}_{15}\text{N}$ , described above is also very near to that of the isomeric  $\alpha$ -coniceine, with

which, however, it is not identical, as  $\alpha$ -coniceine solidifies at  $35^\circ$ .

These experiments show that ammonium formate and ammonia act on acetone in a similar manner, but that the former has, at the same time, a reducing action; the further investigation of the compounds described above is delayed owing to the difficulty of preparing them in large quantities.

—F. S. K.

*Pyridine and its Relations to Quinoline, Isoquinoline, and the Alkaloids.* A. Elinger. J. prakt. Chem. 1890, **41**, 341—359.

THE halogen alkyl additive compounds of certain alkaloids are, as is well known, by the action of freshly prepared moist silver oxide, under suitable conditions, converted into quaternary bases, which are soluble in water, combine with carbon dioxide, and form, with acids, salts which are identical with the corresponding halogen alkyl additive product of the alkaloid, are not decomposed by dilute ammonia, and form crystalline, anhydrous, very stable double salts, identical with the corresponding double salts of the halogen additive products. These double salts, when treated with alkalis, yield a base which is quite different to that obtained by means of silver oxide, and which behaves in all respects like a tertiary base; it is almost insoluble in water, does not combine with carbon dioxide, and its halogen salts are not identical with the corresponding alkyl halogen additive compound.

Isoquinoline behaves in this respect like many alkaloids, so that an isoquinoline nucleus is probably present in many of these compounds; quinoline, on the other hand, does not show a like behaviour as the bases, obtained by decomposing its halogen alkyl additive compounds with alkalis, yield with acids, salts which are identical with the original alkyl halogen additive products. These salts do not give quaternary bases with silver oxide, but bases, the halogen salts of which are identical with the halogen alkyl additive compounds of quinoline.

The behaviour of pyridine has been investigated in this direction, and the author finds that pyridine behaves exactly like the alkaloids and isoquinoline. It would seem, then, that the so-called pyridine ring in quinoline is differently constituted to that in pyridine itself.—F. S. K.

*On the Germination of the Seed of the Castor-Oil Plant* (*Ricinus communis*). J. R. Green. Proc. Roy. Soc. **47**, 146—147.

A FERMENT exists as a zymogen in the resting seed, which is readily developed by warmth and weak acids into an active condition, and splits up the fat into glycerin and (chiefly) ricinoleic acid. Further changes, brought about by the protoplasm of the endosperm cells, form from the latter a lower carbon acid, soluble in water, and crystalline. The proteids of the seed, globulin and albumose, are split up by another ferment, with formation of peptone and asparagin. The reserve materials absorbed by the endosperm are a crystalline acid, sugar, asparagin, and, perhaps, some peptone. The mode of absorption is always dialysis. During the germination, a rennet ferment of considerable vigour is liberated in the endosperm.—J. M. H. M.

*Recent Discoveries in Fine Chemicals.* Chem. Ind. **13**, 177—182.

*Monochloral-antipyrine.*—If concentrated solutions of equal weights of chloral hydrate and antipyrine are mixed, an oily layer is formed, which soon crystallises. If for 4.7 parts of chloral hydrate, 5.3 of antipyrine be taken and each be dissolved in 5 parts of water by the aid of a gentle heat and mixed, large crystals may be obtained of this compound. When re-crystallised from alcohol it has the formula  $\text{C}_{13}\text{H}_{13}\text{N}_2\text{Cl}_2\text{O}_2$ . Its m.p. is  $67^\circ$ — $68^\circ \text{C}$ , and it dissolves in water at  $140^\circ \text{C}$ . to the extent of 7.85 grms. in 100 grms.; it gives, with ferric chloride, the blood-red colour

characteristic of antipyrine, and yields chloroform when heated with potash solution. It also reduces Fehling's solution when warm.

**Dehydrated Compound.**—When this compound is kept for a certain time heated to its melting point, crystals are deposited of a *dehydration compound*, first prepared by Reuter. It is insoluble in water, melts at  $186^{\circ}$ – $187^{\circ}$  C., and is easily distinguished from monochloral-antipyrine by not giving the ferric chloride reaction.

**Bichloral-antipyrine.**—This is obtained if instead of taking equal molecular proportions, a concentrated solution of chloral-hydrate be used in excess. An oily layer is formed from which prismatic needles are obtained containing 2 mols. of chloral to 1 of antipyrine. The melting point of bichloral-antipyrine is also  $67^{\circ}$ – $68^{\circ}$  C., but this compound is more soluble than the monochloral-antipyrine, the proportion being 9.98 grms. in 100 of water at  $14^{\circ}$  C. It gives with ferric chloride the red colouration of antipyrine and reduces Fehling's solution when heated. In water it seems to undergo some dissociation. (*Béhal et Choay, Journ. Pharm. Chim. May 15, 1890, 539. Pharm. J. 1890, 977.*)

**Incompatibility of Antipyrine and Carbolic Acid.**—Millard and Stark first pointed this out (*Pharm. J. 1890, 861*). It has been confirmed more recently by Tardy (*Répertoire, May 10, 209*), who shows that a solution of antipyrine to which a solution of carbolic acid was added, separated after some hours into two layers. The upper layer only contained antipyrine, the lower, an oily liquid containing both antipyrine and carbolic acid. The taste was piquant, and the colour a faint rose; it had a slight odour of phenol, and a specific gravity of 1.13. It was neutral, insoluble in water, but soluble in alcohol and in ether.

**Guaïacol carboxylic acid** has been found to possess extraordinary antiseptic powers. In its preparation, sodium guaïacolate is saturated with carbon dioxide under pressure in the cold, and the mixture is then heated (without changing the vessels) to  $100^{\circ}$  C. The reaction is—

The product is dissolved in water and decomposed by a mineral acid when the guaïacol carboxylic acid crystallises out in combination with 2 mols. of water. The substance melts in the anhydrous condition at  $148^{\circ}$ – $150^{\circ}$  C., gives in solution a blue colour with ferric chloride, and on being sufficiently heated is decomposed into carbon dioxide and guaïacol (*Pharm. J. 1890, 977*).

**Benzanilide**,  $\text{C}_6\text{H}_5 \cdot \text{NH} \cdot \text{COC}_6\text{H}_5$  has been recommended by Hahn (*Pharm. Zeit. 34, (72)*) as a powerful febrifuge in the use of which untoward accompaniments are not observed.

**Methacetin or Para-acetanisidine**—

(*Pharm. Zeit. 34, (55)*), forms small white, almost tasteless plates, melting at  $127^{\circ}$  C., and far more soluble in water than the analogously constituted phenacetin. Its reactions are very similar to those of phenacetin, and only differ in being less intense than those of that compound. 1 cc. of hydrochloric acid dissolves 0.1 grm. of methacetin very easily, whereas the same quantity of phenacetin would prove almost insoluble. Methacetin is useful in rheumatism in the joints, and completely transcends phenacetin in its efficacy in cases of neuralgia of the most varied kind.

**Formyl-para-phenactidine** ( $\text{C}_2\text{H}_5\text{O} \cdot \text{C}_6\text{H}_4 \cdot \text{NH} \cdot \text{CHO}$ ), though constituted analogously to phenacetin, appears to possess no antipyretic powers, but it serves as an antidote in cases of strychnine poisoning.

**Phenylurethane** ( $\text{C}_2\text{H}_5 \cdot \text{OCO} \cdot \text{NH} \cdot \text{C}_6\text{H}_5$ ) and **Pyrodine** (**Acetylphenylhydrazide**) have, neither of them, succeeded well. The latter is reported by Reubers (*Deutsch. med. Woch. 1889, No. 47*) to be a direct blood poison, the antithermic properties of which are really due to destruction of the red blood corpuscles. Guttman, Zerner, and Oestreich report deleterious intoxicating effects.

**Thalline**, though for similar reasons no longer used as an antipyretic, is still used somewhat considerably in the treatment of gonorrhœa.

**Amylene hydrate** has been proved by the researches of Laves and Jastrowitz (*Berl. klin. Woch. 1888, No. 21*) to be a valuable hypnotic, the employment of which is never dangerous and only seldom occasions unpleasant symptoms. Wildermuth (*Neurol. Centr. 1889, No. 15*) has obtained favourable results with epileptics by its employment.

**Rubidium-ammonium bromide** is, according to Lanfenauer and Rottenbiller (*Ther. Mon. 3, 348*, and *Gyogyosaz, 1889, No. 43*) a good anti-epileptic. Its high price is the only thing against it. Lanfenauer states the interesting conclusion that the anti-epileptic action of the alkaline bromides varies directly with their molecular weights.

**The Relative Antiseptic Powers of Isomeric Organic Compounds.** T. Carnelley and W. Frew. *Proc. Chem. Soc. 1890, 90.*

The authors have determined the relative antiseptic powers, in reference to ordinary aerial micro-organisms, of a number of isomeric organic compounds, more particularly di-derivatives of benzene, with the object of investigating the influence of atomic arrangement on this property.

A table of results is given which indicate that, so far as the compounds which have been tried are concerned (and with the exception of the hydroxybenzoic acids), para-compounds are more antiseptic than the corresponding ortho- and meta-compounds. On the whole, compounds containing the carboxyl-group are comparatively weak, while phenols and nitro-compounds are relatively strong antiseptics; para-nitrophenol being, with the exception of  $\alpha$ -naphthol, the most powerful of any of the compounds tried. These results entirely accord with those of Walcott Gibbs and Hare, who have recently investigated the poisonous action of di-derivatives of benzene on dogs.

**Note on the Preparation of Pyrocatechol.** W. H. Perkin, jun. *Proc. Chem. Soc. 1890, 90.*

THE very high price of pyrocatechol (catechol) renders it desirable to discover improved methods of preparing it; the author has, therefore, studied the action of iodhydric acid on guaïacol, which is easily procured at a moderate cost. He finds that an almost theoretical yield of catechol may be obtained by boiling guaïacol with a fuming solution of hydrogen iodide. Details are given in the paper.

## PATENTS.

**Improvements in Apparatus for Filtering Perfumes, Tinctures, Essences, Cordials, and other Liquids.** F. L. Johnstone, Henley-on-Thames. Eng. Pat. 1888, February 6, 1890, 6d.

THE object of this invention is to filter the insoluble matter held in various liquids, without the loss of strength or aroma by evaporation, by enclosing them whilst filtering in air-tight vessels and pipes. The liquid to be filtered is poured into a holder, made of any suitable material, having a biogged lid which can be closed air-tight. One end of a pipe is attached to this lid, and the other to an air-vessel connected with a vacuum pump. The pump on being set in motion draws air from the filtered-liquid receiver below it, which also has an air-tight lid, and compresses the air in the air-vessel above it. A tap under the air-vessel is then turned off and another at the upper part turned on, when the compressed air passes into the liquid-holder, forces the liquid through the filtering material it contains and through further materials, finally flowing through a spiral tube into the filtered-liquid receiver, from which it can be drawn off by a tap. There are three claims.—E. S.

## XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

### PATENTS.

*Process for Rendering Cardboard and the like Impervious to the Action of Photographic Chemicals, and suitable for Photographic Purposes.* W. F. Greene, London. Eng. Pat. 7747, May 9, 1889. 6d.

THE object of this invention is to prepare ordinary cards in such a manner that permanent photographic prints may be produced directly on them, thus avoiding the processes of mounting and rolling.

The cards are coated one or more times with—

Oxide of zinc.....	1 part.
Turpentine .....	3 parts.
Pale gold size .....	1 part.

With or without a preliminary treatment in dilute sulphuric acid (2:1). When dry the cards are sensitised and printed in the usual manner. There are ten claims.—F. H. L.

*An Improved Method of Deciding the Correct Exposure in Platinotype Printing, and Apparatus therefor.* C. R. Crawford, London. Eng. Pat. 10,504, June 28, 1889. 6d.

THE printing frame containing the negative to be printed on platinotype paper is exposed side by side with an actinometer, made by preparing a negative of a series of numbers or letters, each one of which is covered with one more thickness of tracing paper or other translucent material than the previous letter.

Under this negative is placed a piece of ordinary sensitised paper, and the printing is carried on till the platinotype paper is found to be correctly exposed. The last visible number on the actinometer is then noted, and the operation can be repeated with fresh papers, the exposure being continued till the same number is visible in the other frame.—F. H. L.

*Improvements in or relating to the Manufacture of Photographic Films.* A. J. Boulton, London. From George Eastman, Rochester, U.S.A. Eng. Pat. 19,897, December 10, 1889. 6d.

A SOLUTION is prepared by dissolving 9,000 grains of soluble gun cotton and 5,460 grains of camphor in 112 ounces of methyl-alcohol and filtering; to avoid shrinkage on drying it is preferable to add 28 ounces of "fusil" oil and 7 ounces of amyl acetate. The coating table, which may have either a polished or dead surface, is covered with a weak solution of mineral wax or bees-wax in "benzine" and a thin film of the solution of gun-cotton spread upon it by means of a longitudinal spreader. The thickness of this film should be from 3 to 5 thousandths of an inch.

The film is then washed with a 2 or 3 per cent. solution of sodium or potassium silicate, and when dry is coated with emulsion. When the sensitive film has dried, the whole is cut into pieces of suitable width and stripped from rigid support.—F. H. L.

*Improved Apparatus for Coating Photographic Plates.* F. Bishop and A. Cowan, London. Eng. Pat. 304, January 7, 1890. 8d.

THE trough for holding the emulsion is made of the usual V-shape, one side being bedded on to a hot-water chamber, the other being adjustable by means of screws, so as to enable the thickness of the film being easily regulated, and to ensure its absolute uniformity. The hot-water chamber is pivoted on balanced levers in such a manner that plates of varying thickness may easily pass underneath. For coating large plates, the trough is provided with a rubber lip which rides on the surface of the glass and compensates for its inequalities. The plates are supported in passing under the trough on knife-edged rails at their extreme edges, and guided by means of rollers; gutters are also provided to catch any superfluous emulsion, and prevent its soiling the back. The specification is accompanied by drawings of the trough.—F. H. L.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*The Annual Report (Fourteenth) of H.M. Inspectors of Explosives, for 1889.*

THIS report contains a full account of the working of the Explosives Act (1875) during the year 1889. The only modifications made by the Secretary of State were for the purpose of giving increased liberty in the method of packing the explosives to the manufacturers. The number of factories now licensed is 122, an increase of 10 on the previous year; the total number of magazines is now 357, being an increase of four on last year.

Increased facilities for storage of different explosives in the same magazine are now given. There were 132 accidents during the year, causing 39 deaths and injuring 102 persons. This shows a slight increase in the deaths over 1888, but is below the average for the last 10 years, and the number of deaths from accidents in manufacture was only seven. Dr. Duprè reports that the condition of the various authorised explosives examined during the year was, with two exceptions, highly satisfactory. The year has been characterised by continued activity among inventors, a great number of new explosives having been submitted for examination. A noticeable feature is also the gradual displacement of kieselguhr dynamite by the various gelatinised preparations. The new explosives examined were: Bronolith, 4 varieties; Diripsite, Trench's explosives, 2 varieties; Von Dahmen's dynamite; Fortis, 3 varieties; Fortisine; Stonite; Meganite; Blasting Matagnite; Forcite; Smokeless rifle powder; and Cycene. The last two are still under consideration, and all the others passed the tests satisfactorily except Diripsite, Meganite, 1 variety of Trench's explosive, 2 varieties of Bronolith, and 1 variety of Fortis. Bronolith is a picrate mixture, the samples passed were those rich in nitre; Diripsite is a chlorate mixture; Trench's explosive consisted mainly of gun-cotton and nitre, with the addition in one case of dinitrobenzene and in the other of picric acid, the latter being the one which failed to pass the test; Von Dahmen's dynamite (see this Journal, 1890, 105); Balistite is essentially a blasting gelatin, containing a very high proportion of gun-cotton; Fortis (this Journal, 1888, 401); Fortisine is a new name for fortis Nos. 3 and 4; Black Dynamite is essentially dynamite No. 1, containing, in place of ordinary calcined kieselguhr, kieselguhr only very partially calcined (this Journal, 1889, 818); Meganite is a gelatin dynamite containing sodium nitrate in place of potassium nitrate; Blasting Matagnite is a blasting gelatin containing nitrobenzene; Forcite is substantially a gelatin dynamite.

The importations of explosives during the year show a considerable increase as compared with those of 1888. The inspectors again express their views that "the capricious action of the railway companies in carrying some explosives and refusing to carry others (though sometimes identical in composition or practically so) led to much surreptitious conveyance."

Owing to "the way in which all explosives, whether manufactured in or imported into this country, are carefully watched as to their chemical stability, general safety, and method of packing," the inspectors consider that "no real reason exists why all authorised explosives should not be carried by the railways under suitable regulations," and they emphatically repeat that "all authorised explosives may be carried at least as safely as (and in several cases with considerably greater freedom from risk than) gunpowder."

There have been a few malicious attempts to destroy life and property by explosion, and several infernal machines had to be examined. An account is given of the principal foreign explosions, and the great Antwerp explosion of 6th September 1889, was specially investigated, and from the special report thereon large extracts are published in the present report. Experiments were also made as to the sensitiveness of blasting gelatin and gelatin dynamite when in the frozen and unfrozen condition, and although the results are not altogether concordant or conclusive, it would appear that blasting gelatin is more sensitive to explosion by percussion when frozen than when unfrozen. In the case of gelatin dynamite the sensitiveness of the variety known as "Gélinite" appears not to be appreciably affected by freezing. "Comparing blasting gelatin and gelatin dynamite it would seem that (a) of the unfrozen varieties blasting gelatin is the less sensitive; (b) of the frozen varieties blasting gelatin is very much the more sensitive; (c) unfrozen blasting gelatin is less sensitive than gelatin dynamite, whether in a frozen or unfrozen condition; and (d) frozen blasting gelatin is vastly more sensitive than gelatin dynamite in whatever condition." "It also appears that unfrozen dynamite is distinctly more sensitive to explosion than blasting gelatin or gelatin dynamite, in whatever condition; the sensitiveness of frozen blasting gelatin approaching it the most nearly. Both blasting gelatin and gelatin dynamite appear to furnish less effective results when exploded in a frozen condition than when exploded in a plastic condition."

The more important petroleum accidents, including the petroleum fire which resulted from the explosion of the ammunition factory at Antwerp previously noticed, are also referred to.—W. M.

*Notes on the Erosive Power of Compressed Gases.*  
Dauvrée. Mém. de l'Artillerie de la Marine, 2, 1889, 245; and Proc. Inst. Civil Eng. 1890, 53.

The author attributes the erosive action of powder to three distinct causes. First, there is the physical action, caused by the elevation of the temperature of the metal which is in contact with the superheated gases. It is this elevation of temperature which twists and contorts thin layers of the steel into tortuous forms. Secondly, there is the chemical action due to the combination of these small particles with the elements of which the gases are composed. The most noteworthy result of this combination is the production of iron pyrites. Thirdly, there is the mechanical action due to the impact of the gases against the walls which enclose them.

With dynamite, nitro-glycerin, and gun-cotton, this mechanical action is much the most marked, while the calorific and chemical effects of explosion are not always perceptible. In comparing the effects produced by the explosion of these agents with that of gunpowder, the much greater erosive effect produced by the former the author attributes to the rapid increase of the erosive power of gases as their pressure and temperature rise. He attributes

the pitting and distress in the surface of the metal in contact with the gases, to the fact that these are so highly compressed at the instant of explosion as to act like solid bodies.

*Smokeless Powder (Experiments made at Essen in July and August, 1889).* Revue d'Artillerie, 35, 1890, 486; and Proc. Inst. Civil Eng. 1890, 85—87.

These experiments were made to ascertain the ballistic effect of Nobel's powder, as regards maximum pressure and muzzle velocity in four guns, varying in calibre from 5 to 8½ centimetres, that is to say, from 1·968 to 3·317 in.

The article commences with a description of the powder taken from the specification of Nobel's patent of 31st January 1888. According to this it is a substance somewhat resembling horn in appearance, composed of nitro-glycerol, nitro-cellulose, and camphor, and is therefore a kind of explosive gelatin with camphor added, and with a considerable preponderance of nitro-cellulose. It may be made into grains of any form, and burns sufficiently slowly as to admit of its use in guns in lieu of ordinary powder, and it possesses the advantages of leaving very little residue and little or no smoke. The object of adding the camphor is to assist the dissolution of the nitro-cellulose, and also to moderate the rapidity of combustion. The proportion of camphor indicated is from 10 to 30 per cent. of the weight of the nitro-glycerol. When nitro-glycerol predominates it is recommended to make use of a volatile liquid capable of dissolving the nitro-glycerol and the camphor, such as benzene. When, on the contrary, nitro-cellulose predominates, a liquid such as acetic ether or acetone is used.

Two methods of preparation are described. In the first method 10 parts by weight of camphor are dissolved in 100 parts of nitro-glycerol, to which 200 parts of benzene are added. Into this mixture is introduced 50 parts of dried pulp of soluble gun-cotton. The benzene is then evaporated, and the materials thoroughly mixed by passing them between two hollow cylinders heated by steam to a temperature of 43·3° C. to 60° C. When the mixture is sufficiently homogeneous it is moulded into grains or rolled out into sheets, which are afterwards cut up into grains or pellets ready for use.

The other method is as follows:—Mix together 100 parts of nitro-glycerol, 10 to 25 parts of camphor, and 200 to 400 parts of acetate of amyl. Into this put 200 parts of dry pulp of soluble gun-cotton. This mixture is kneaded until the gun-cotton is completely dissolved. The pasty matter thus obtained is reduced into thin sheets, from which the moisture is expelled by heat, and the dry material is formed into grains or pellets fit for use.

The article then refers to a second patent of Nobel, dated 26th March 1889, in which there is no mention of camphor. The essential elements are as before, nitro-glycerol and nitro-cellulose, with the addition of nitrated starch, or of nitrated dextrine, and a certain quantity of an alkaline nitrate, chlorate or picrate.

The article then proceeds to give an account of experiments made at Essen with the Nobel powder in August 1889. The powder used was composed of a mixture in equal proportions of nitro-glycerol and nitro-cellulose kneaded together and made into cubical grains.

Experiments were made with cubical grains of four dimensions, viz., 0·1181, 0·1378, 0·1575, and 0·1969 in. of a side, as previous to these experiments nothing was known either as to the best weight of charge or the size of grain suitable to the calibre of the guns. The guns used on the experiments were as follows:—

No. 1—calibre, 1·968 in.; length of bore, 40 calibres; weight, 490 lb.

No. 2—calibre, 2·362 in.; length of bore, 40 calibres; weight, 862 lb.

No. 3—calibre, 2·952 in.; length of bore, 28 calibres; weight, 904 lb.

No. 4—calibre, 3·317 in.; length of bore, 40 calibres; weight, 2,310 lb.

The results are given in the following table:—

Description of Gun.	Date.	No. of Round.	Charge.	Size of Grain.	Projectile.	Velocity at 110 ft. from Muzzle.	Maximum Pressure.

### XXIII.—ANALYTICAL CHEMISTRY.

#### *A new Apparatus for Fractional Distillation in Vacuo.*

H. Gautier. Bull. Soc. Chim. 1889, 2, 675—676.

This apparatus consists of a cylindrical glass tube, to the bottom of which a number of narrower tubes are fused, each of which is connected with a separate receiver. Into the upper portion a second tube is ground, which may be closed

by a cork with two holes. Through one a tube passes connected with the distilling apparatus, while the tube in the other hole is connected with the vacuum pump. By turning the cylinder round the liquid may be led into any of the receivers.—J. B. C.

*Viscosimeter; for Observations of Oils under constant Temperature.* C. Engler and A. Kunkler. *Diagl. Polyt. J.*, 276, 42—47.

THE apparatus represented in Figs. 1, 2, and 3, has been designed to remedy the two defects of Engler's viscosimeter, viz., that in observations at high temperatures, the temperature of the oil varies sensibly during the running off,

Fig. 3.

Fig. 1.

Fig. 2.

and the extremity of the efflux tube undergoes a gradual cooling. It is an octagonal jacketed air bath, 35 cm. high, and 20 cm. broad. The feet *a* stand in the ring of a tripod in such a way that the level of the bath can be adjusted so as to control the level of the liquid in the viscosimeter itself contained in the upper portion of the bath. The heating surface *b* is arched; above this and supported by the stand *c* is the measuring vessel *e*, cut off from direct radiation from *b* by the asbestos plate *f*. Above this is the dividing plate *g* upon which the viscosimeter is supported, the flow of oil passing to *e* through the opening *h*. Circulation of hot air into the upper chamber takes place through *h* as also through the four oval tubes *i* (Fig. 2). Through the cover plate pass the thermometers *u*, *s*, the axis of stirring apparatus with the stop *t* for the efflux tube, and the funnel *r* for introducing the oil, heated to the required temperature in the apparatus II (Fig. 3.) In the sides and cover, windows are let in the bath for illuminating, the former to permit observations of the level in the viscosimeter and the efflux of the oil into *e*. The method of using the instrument for the observations in question need no special description; full details of manipulation are given in the original.

That the instrument fully satisfies the required condition of constant temperature, is stated by the authors in the following terms: Up to 100° the temperature in all parts of the bath—heated with no charge of oil in the viscosimeter—is equal and constant, excepting in the lower stratum of air in the viscosimeter itself, which is of course shielded from the general circulation. This difference disappears with the introduction of the oil. At temperatures higher than 100° the air above the viscosimeter is of somewhat lower temperature, but the difference at 150° did not exceed 4°.

—C. F. C.

*The Action of Nitric Acid on Aluminium.* A. Ditte. *Compt. Rend.* 110, 782—784.

WHEN aluminium is placed in dilute nitric acid, it appears to be unacted upon, but after some time small bubbles of

gas appear on the surface of the metal and it gradually dissolves; the evolution of gas and dissolution of the metal is much hastened by allowing the action to take place in vacuo. This shows that the slowness of the action under ordinary conditions is due to the formation of a protective layer of gas on the surface of the metal. The chief constituent of the evolved gas is nitrogen; nitric oxide is also present, and ammonia is retained in solution. If a little platinum chloride be added at the commencement of the reaction, the aluminium becomes coated with a slightly adherent coat of reduced platinum and dissolves with evolution of a mere trace of nitrogen. Large quantities of ammonia are found in the solution.

The action does not cease when all the free nitric acid is neutralised, for aluminium will dissolve in solutions of its salts forming basic compounds. The action is very slow in the cold, but on boiling aluminium in a solution of its nitrate, it dissolves with evolution of hydrogen, and a white precipitate is formed, having the composition—

These experiments elucidate the action of water on aluminium; in this case a double protective coat of alumina and hydrogen is formed; if the hydrogen be prevented from accumulating by boiling and the alumina dissolved immediately it is formed, the metal will dissolve. This is exactly what takes place when aluminium is boiled in a solution of one of its neutral salts, with the sulphate  $4\text{Al}_2\text{O}_3 \cdot 3\text{SO}_3$  is formed, with the nitrate  $2\text{Al}_2\text{O}_3 \cdot \text{N}_2\text{O}_5 \cdot 10\text{H}_2\text{O}$ , and with the chloride  $\text{Al}_2\text{Cl}_6 \cdot 10\text{Al}_2\text{O}_3$ . The truth of this explanation is borne out by the fact that solution of salts, such as sodium chloride, which do not dissolve alumina, have no such action. (This Journal, 1890, 547 and 549.)

—A. L. S.

*Reagent for Free Chlorine in Hydrochloric Acid.*

G. A. Le Roy. *Boll. Soc. Chim.* 1889, 2, 729.

THE author recommends the use of diphenylamine to detect minute quantities of free chlorine in hydrochloric acid. A few small crystals of diphenylamine in presence of free chlorine produces immediately a blue colouration.—J. B. C.

*Volumetric Estimation of Copper.* A. Etard and P. Lebeau. *Compt. Rend.* 110, 408—410.

A CONCENTRATED solution of cupric bromide, mixed with strong hydrobromic acid, becomes deep violet in colour, like potassium permanganate, and almost opaque. The colour is due to a compound of cupric bromide and hydrobromic acid, which is decomposed by addition of water with formation of the ordinary green, and then blue, of cupric solutions.

If a titrated solution of stannous chloride be run into the violet liquid the colour is discharged as fast as the cupric bromide is reduced to cuprous bromide, and the end reaction is as sharp as in the titration of ferrous salts by permanganate.

In practice the copper compound may be in solution, if concentrated hydrochloric acid and some strong hydrobromic acid be added before titration, thus effecting considerable economy in consumption of the latter reagent. Reducing and oxidising agents must be absent. The test analyses with pure cupric sulphate are satisfactory.

—J. M. H. M.

*Chrome Iron.* S. Meunier. *Compt. Rend.* 110, 424—426.

By the action of a current of hydrogen on a mixture of ferrous and chromic chlorides contained in a red-hot porcelain tube, a silver-white alloy or compound of iron and chromium is formed, magnetic, and not attacked by hydrochloric or nitric acid and very slightly by aqua regia. It contains 35.01 per cent. of iron, and 64.80 per cent. chromium. When this substance is oxidised at a red heat by a current of steam it is completely converted into chromite, having all the properties of the native mineral and giving on analysis, ferrous oxide 32.41 per cent., chromic oxide 63.06 per cent.—J. M. H. M.

*Determination of Free Halogens and of Codides in presence of Chlorine and Bromine.* P. Lebeau. *Compt. Rend.* **110**, 520-522.

*Determination of Iodides.*—To the solution of iodide, contained in a 200 c.c. flask, are added 30–40 c.c. of carbon disulphide and a few drops of sulphindigotie acid. A titrated solution of bromine water is then run in from a stoppered burette until the colour of the indigo is just discharged; the iodine, as fast as it is liberated, dissolves in the carbon disulphide. The bromine water is titrated from time to time against standard potassium iodide.

*Determination of Free Halogens.*—The free halogen is shaken in a stoppered flask with water and zinc powder. The solution of neutral zinc bromide, chloride, or iodide, thus formed is titrated with standard silver nitrate, with potassium chromate as indicator. The bromine solution used in the previous process may be checked against pure silver nitrate in this way.—J. M. H. M.

*Action of Sodium Thiosulphate on Silver Salts.* J. Fogh. *Compt. Rend.* **110**, 709–711.

The reaction—

$2 \text{AgNO}_3 + \text{Na}_2\text{S}_2\text{O}_3 = 2 \text{NaNO}_3 + \text{Ag}_2\text{S} + \text{SO}_3$  takes place quantitatively. In an actual experiment the reaction was accompanied by the liberation of 46 eals. of heat. Two stages are observed in this reaction, a thiosulphate of silver is first momentarily formed and then decomposed into silver sulphide and sulphuric anhydride. It is calculated that 5.2 eals. are liberated in the first stage and 40 eals. in the second.

When an excess of sodium salt is present the silver thiosulphate is dissolved as fast as it is produced with the formation of a double salt and liberation of 34.8 eals.

The action of sodium thiosulphate on the haloid salts of silver is thus explained, since the decomposition of silver chloride, bromide and iodide is accompanied by the absorption of -26, -34.6, and -48.4 eals. respectively. The first two of these numbers being less than the heat of dissolution of the silver thiosulphate formed in sodium thiosulphate, the respective decompositions can readily take place without the aid of external energy.

For this reason solutions of the double thiosulphate of sodium and silver are precipitated by potassium iodide, but not by the chloride or bromide.—S. B. A. A.

*Some Compounds of Mercury Chloride with Ammonia.*

G. Andre. *Bull. Soc. Chim.*, 1889, **2**, 145–153.

See under XX., page 647.

*Method of Analysis applicable to Water for feeding Boilers, to determine the amount of Anti-incrustation Agent necessary.* L. Vignon. *Bull. Soc. Chim.* 1889, **2**, 596–603. (See following Abstract.)

ROSSEL, in his report for 1888 to the Swiss Steam-Users Association (Zürich, Zürcher and Furrer, 1889), states that, theoretically, the best water for boiler use would be pure distilled water, rendered slightly alkaline. To render the water ordinarily available as suitable as possible, he recommends that sodium carbonate, and this substance alone, should be added to soften the water. The reactions which take place are—

The sodium bicarbonate formed is again decomposed at the temperature of the boiler and regenerates the carbonate. After the reaction the chlorides and sulphate of sodium remain in solution, while the carbonates of calcium and magnesium form a pulverulent and non-adherent precipitate.

An excess of sodium carbonate is dangerous as it would finally attack joints and taps.

We must therefore determine—

I. The quantity of carbonate necessary to combine with free carbon dioxide and to precipitate the bicarbonates of calcium and magnesium (this quantity being continually regenerated).

II. The quantity of carbonate necessary to precipitate magnesium chloride and calcium sulphate.

For this purpose a special method of analysis of the feed-water has been devised. The reagents required are—

(1.) A clear solution, containing 1.80 per thousand  $\text{Ca}(\text{OH})_2$  (saturated at 15° and decanted).

(2.) A solution containing 5 grms. of phenolphthalein in 100 cc. of 93 per cent. alcohol.

(3.) A neutral solution of calcium chloride containing about 5 per cent.

(4.) A solution of sodium carbonate containing 1 per thousand. The soda crystals to be used finally for softening the water may be employed instead of pure substance in making up this solution.

(1.) *Estimation of carbonic acid present in the free state, or combined with carbonates to form bicarbonates.*—50 cc. of distilled water and 10 drops of phenolphthalein solution are poured into a 100 cc. graduated cylinder provided with a glass stopper; 50 cc. of the feed-water, 10 drops of phenolphthalein and 5 cc. of the calcium chloride solution (to convert any magnesium bicarbonate into the calcium salt) are poured into a second cylinder, similar to the first.

The distilled water is then just coloured by adding 0.2 to 0.5 cc. of the lime-water from a burette, and lime-water is added gradually to the feed-water. The temporary colouration produced by each addition disappears quickly at first, but the reaction gradually slackens, and it is best to shake the solution well and to wait some little time between successive additions of the lime-water. When the colour of the feed-water has become constant (this takes place in less than an hour) and approximately equal in tint to that of the standard, the two are made exactly equal in volume and of the same colour by additions of water and lime-water.

The difference between the lime-water added to the standard and that added to the feed-water gives immediately the amount of free carbon or that combined with a carbonate to form a bicarbonate. If the analysis has been carried out precisely according to the above directions, and  $n$  be the number of cc. of the lime-water solution containing 1.80 per thousand  $\text{Ca}(\text{OH})_2$  required by the feed-water, the amount of pure  $\text{Na}_2\text{CO}_3$  per cubic metre required for purpose I. is theoretically 514  $n$  grms.; but the author recommends that this amount be augmented by 20 per cent. and increased to 616  $n$  grms., in order to allow for impurities in the commercial product and to make the water slightly alkaline. If  $V$  be the mean volume of water contained in the boiler while working, expressed in cubic metres, the weight of  $\text{Na}_2\text{CO}_3$  to be added once for all, after the boiler has been cleaned, is therefore 616  $nV$  grms. for purpose I.

(2.) *Determination of  $\text{Na}_2\text{CO}_3$  required to precipitate the metals present as chlorides and sulphates.*—100 cc. of the feed-water is poured into a 250 cc. graduated cylinder. The amount of lime-water necessary to neutralise exactly is added, then 5 cc. of the phenolphthalein solution. The liquid should remain colourless after being shaken up. It is then filtered and allowed to settle, and half the total volume (corresponding to 50 cc. of the feed-water) is introduced into a 500 cc. graduated cylinder. A titrated solution of sodium carbonate is then added till the colour becomes distinctly red; it is useful to compare with a standard made by adding the same quantity of phenolphthalein and 0.3 to 0.5 cc. of the  $\text{Na}_2\text{CO}_3$  solution to an equal volume of distilled water. As a rule, the results obtained are very definite; but when the water contains much magnesium chloride and magnesium sulphate (which rarely occurs) the end reaction is not well marked.

If  $V'$  be the average consumption in cubic metres per 24 hours, and  $x$  the number of grms. of sodium carbonate ( $\text{Na}_2\text{CO}_3$ ) required per cubic metre under head  $H$ , then each day  $Vx$  grms. of sodium carbonate must be introduced into the boiler before getting up steam.—P. J. H.

*On a new Method of Analysis applicable to Water for Manufacturing Purposes, and for feeding Boilers.*  
L. Vignon. Bull. Soc. Chim. [3], 3, 2—4. (See preceding Abstract.)

THREE notes have previously been published on this subject (Bull. Soc. Chim. [3], 1, 903; this Journal, 1889, 138, and above). Two improvements in the details of the analysis are now suggested.

(1.) Ordinary distilled water may contain as much as 5 cc. of  $\text{CO}_2$  per litre; it is advisable, therefore, to prepare the two standard-tint solutions with distilled water which has just been boiled gently for 15 minutes in a platinum or porcelain evaporating dish. The use of glass would vitiate the results by introducing alkali.

(2.) In operation (2) above, it is more convenient and expeditious to get rid of the excess of  $\text{CO}_2$  by boiling in the way just described, than to precipitate with lime water.

—P. J. H.

*Electrolytic Separations.* E. F. Smith and L. K. Frankel.  
J. Franklin Inst. 1890, 129, 236—247.

(1.) *Cadmium from Cobalt and Nickel.*—Cadmium may be completely separated from cobalt. On passing a current yielding 0.4 cc. of  $\text{O}_2$  gas per minute for 14 hours into solutions of these metals (0.1690 gm. of each in 200 cc. water) containing 4.5 grms. of potassium cyanide, the whole of the cadmium is deposited without any admixture of cobalt. The separation of cadmium from nickel was not found possible with any approach to accuracy.

(2.) *Mercury from Zinc, Nickel and Cobalt.*—Mercury may be satisfactorily separated from zinc; solutions of these metals (0.2440 gm. each in 200 cc. water) containing 3—4.5 grms. of potassium cyanide, deposit the whole of the mercury ( $\pm 0.2$  per cent.) when treated for 16 hours with a current yielding 0.5 cc.  $\text{O}_2$  gas per minute. The separation of mercury from nickel is only approximate; solutions of the same strength as before containing 4.5 grms. of potassium cyanide and treated for 16 hours with a current of 0.4 cc. gave results from 0.2 to 0.6 per cent. too low.

The separation of mercury from cobalt is attended with still greater difficulty; solutions of mercury (0.225 gm. in 200 cc. of water) and 25—75 per cent. of cobalt, containing 3 grms. of potassium cyanide gave the best results on treatment for 16 hours with a current of 0.5 cc., the error being from  $+0.26$  to  $+0.35$  per cent., with equal quantities of mercury and cobalt and 2.2 grms. of potassium cyanide, the error was  $-0.60$  per cent.

(3.) *Silver from Copper, Zinc, Nickel, and Cobalt.*—In these cases it is only by the use of extremely feeble currents that even an approximate separation can be effected.

In solutions of silver and copper (0.1788 gm. of each in 200 cc. water) containing 4.5 grms. of potassium cyanide, and heated for 16 hours with a current of from 0.15 to 0.40 cc.; the error varied from  $-0.33$  to  $+0.60$  per cent.

No difficulty is experienced in separating silver from zinc; in solutions containing zinc instead of copper and treated in the same way, the error varied from  $-0.05$  to  $-0.5$  per cent. Equally good results were obtained from solutions containing nickel.

The separation of silver from cobalt is approximately complete ( $\pm 0.33$  per cent.) if the amount of potassium cyanide is reduced to 3 grms. for the same amount of metal as before.

The success of the above separations depends upon the exact proportion of potassium cyanide to the metals in solution, and upon the use of the proper current strength.

(4.) *Copper from Cadmium in the presence of Sulphuric Acid.*—The best results were obtained when a solution of copper sulphate (0.1975 gm. of copper) and cadmium

sulphate (0.1828 gm. of cadmium) in 130 cc. of water and 15 cc. of sulphuric acid (sp. gr. = 1.09) is subjected to a current of from 0.2 to 0.3 cc. The error varies from  $+0.05$  to  $-0.65$  per cent. (See also this Journal, 1889, 639, and 1890, 108.)—S. B. A. A.

*The System of Amalgamation of Gold Ores in use at the Massachusetts Institute of Technology.* R. H. Richards.  
Technology Quart. 3, 45—51.

THE object of the system is to make exact quantitative experiments with a small stamp battery. The difficulties to be overcome were in the first place to avoid loss or gain of gold, which always occurs with amalgamated copper plates, a portion of the gold being always retained in the amalgam remaining on the plates. The copper plates first used were  $\frac{1}{32}$  inch thick, and after each operation the plates were dissolved up. This necessitated new copper plates for each operation. As new copper plates amalgamate badly at first until a certain quantity of gold has been taken up, this second difficulty is overcome by amalgamating the plates to begin with, by substituting a silver amalgam for the gold amalgam, and subsequently separating the silver. The silver amalgam is made by dissolving silver in nitric acid diluted with an equal weight of water, and then adding about ten times as much mercury as silver. The silver is all precipitated, forming a pasty amalgam. The amalgam is washed with water, squeezed through chamois skin until it has the consistence of soft putty, and is then applied to the bright surface of the plates with a hog's bristle brush. The author finds that the use of silver amalgam does away with the necessity of dissolving up the plates, as the gold is deposited only on the surface of the amalgam and can be completely cleaned off. The amalgam on the plates should not be allowed to get too hard or too soft. If too hard it may fail to catch the gold; if too soft, mercury will flow at the lower end of the plates. A quantity of mercury varying from 1 to  $1\frac{1}{2}$  oz. should be fed to the stamps for every oz. of gold contained in the ore under treatment. This mercury should be fed a little at a time every half hour. If the plates are inclined to stain, a lump of cyanide of potassium held a moment on the spot will remove it. If an ore contains  $\text{FeSO}_4$  or  $\text{CaSO}_4$ , as a result of oxidation of iron and copper pyrites a little lime should be added along with the ore. The use of oil in the mill should be restricted as this also causes the yellow stain.—J. B. C.

*Some Points in the Determination of Silica in Silicates by Fusion with Alkaline Carbonates.* J. P. Gilbert.  
Technology Quart. 3, 61—68.

THE author used a sample of blast-furnace slag containing alumina and lime and a little magnesia, and first determined the influence of temperature employed in evaporating off the  $\text{HCl}$  to render the silica insoluble after fusion. The temperatures employed were those of the water-bath,  $125^\circ$ , an iron plate over a Bunsen burner and  $280^\circ$ . The results show that the silica was practically rendered insoluble at the temperature of the water-bath, but the amount of foreign matter in the silica was in general perceptibly higher at the higher temperature of dehydration. This is probably due to the alumina being rendered partially insoluble in acid. The next point determined was the effect of salts such as magnesium chloride, which decompose easily, and which might form insoluble silicates at a comparatively low temperature. The slag used for these determinations contained 35 per cent. of lime, 45 per cent. of magnesia, and 15 per cent. of alumina. This series of results differs from the first, mainly in the large amount of impurity in the silica and the large amount of silica in the alumina when the dehydration is effected at a temperature of  $280^\circ$ . The best results were obtained at a temperature of  $120^\circ$ . The increase of silica in the alumina as the temperature increased would seem to be due to the magnesia, for the conditions were in all other respects the same as in the analyses of the other slag. These results indicate that there is no danger of the silica combining

with the magnesia at  $120^{\circ}$ , and that at this temperature the silica is almost completely dehydrated, the calcium chloride probably assisting in the dehydration.

Another series of analyses was made with orthoclase practically free from lime and magnesia. This series differs from the previous one in that the higher temperature is not accompanied with an increased amount of silica in the filtrate. This would seem to furnish a confirmation of the view, that there was a recombination of the silica and the magnesia at the temperature of  $280^{\circ}$  in the magnesian slag; and the fact that the amounts of silica found in the alumina are higher than those in the lime slag indicates the beneficial effect of the calcium chloride on the dehydration of the silica. The author further found that owing to incomplete separation of silica from an alkaline silicate at  $120^{\circ}$ , the amount of silica in a given sample decreases with each successive fusion. A series of experiments was made by Lindo's method. This consists in largely diluting after extracting the fused mass so that on the addition of HCl no precipitation occurs. In this way he obtained on evaporation what he called "vitreous silica." Samples of glass were analysed as follows:—The powdered glass (1 grm.) was fused with five parts of sodium and potassium carbonates and the mass treated with 400 cc. of boiling water, on acidifying with dilute HCl, a clear solution was obtained. This was evaporated to dryness on a water-bath, heated to  $125^{\circ}$ , and the silica thus obtained fused and treated as before. The silica obtained by the second fusion was weighed and treated with HF. The two filtrates were combined and evaporated to dryness, heated to  $125^{\circ}$  for one hour, and the residue insoluble in HCl filtered off. In this case it was found that a considerable portion of silica fails to be dehydrated by one evaporation and heating to  $125^{\circ}$ . The silica is very pure owing probably to it being easily washed, or it may be due to the absence of any large quantity of alumina.

The author has further made a series of determinations, which seem to justify the inference that in presence of much alumina it is not possible to get as pure silica as is easily obtained when only salts of the alkalis or alkaline earths are present. When evaporation is carried out in presence of free sulphuric acid the results are more satisfactory, but the amount of alkaline sulphates introduced seriously interferes with the determination of the bases present. These results seem to justify the recommendation that has been made, viz., that in the analysis of silicates the silica is best determined by dehydration with sulphuric acid when it is admissible, and that the bases should be determined after the decomposition of the silicate by hydrofluoric acid.

—J. B. C.

*A New Reagent for Cane Sugar, Grape Sugar, and Pyrogallol.* E. Mathieu-Plessy. Bull. Soc. Ind. Mulhouse, 1890, 69—72.

THE new reagent is prepared by heating together to  $200^{\circ}$  a mixture of 45 parts of ammonium nitrate, 34 of lead nitrate, and 21 of lead oxide. The fused mass is cast in slabs. Its melting point, namely  $102^{\circ}$ , is lower than that of any of its constituents. It contains lead para-nitrate, which, when the mass is melted, dissolves in the excess of ammonium nitrate. To apply the test, the reagent is gently heated till melted, and then a small quantity (say 5 mgrms.) of the substance to be tested dropped on to it. The following characteristic colourations are so obtained: with glucose a cherry red, with cane sugar a light brown, and with pyrogallol a chrome-green.—E. B.

*On Commercial Turpentine Oil.* A. Wilson. Chem. Trade J. 6, 316. (Compare this Journal, 1890, 330 and 557.)

ADULTERANTS of oil of turpentine are petroleum and shale spirit, coal tar naphtha, rosin oil and rosin spirit, while an equally dishonest addition is that of the inferior Russian oil of turpentine to the French or American product. The author records the limits within which the samples he has examined ranged. Sp. gr. varied between 0.862 and 0.870. The specific rotatory power is not conclusive, although a

sample giving a high value is certainly pure. The maximum value for the D line obtained during the examination of 20 samples was  $+15.29$ , and the minimum  $+12.05$ , the instrument used being a Laurent. French oil of turpentine is levo-rotatory.

Rosin oil may be detected by steam distillation and subsequent treatment of the residue with stannic bromide, which yields a violet colour, or with acetic anhydride and sulphuric acid, giving a red or reddish violet colouration. The halogen absorption of genuine oil of turpentine is about 215 for bromine and 331 for iodine, while petroleum and shale spirit absorb 30 and 70 per cent. of bromine respectively. The behaviour on distillation, especially when a dephlegmator is used, is useful in detecting shale and petroleum spirit, the boiling point of a genuine sample generally lying between  $156^{\circ}$ — $160^{\circ}$  C. Armstrong's method (this Journal, 1890, 557,) for the detection of petroleum spirit by polymerisation of the turpentine with sulphuric acid and distillation in a current of steam is useful, but not applicable for the recognition of rosin spirit, it being attacked by sulphuric acid.—B. B.

*On the Oxidising and Decolourising Properties of Charcoal.* P. Cazeneuve. Compt. Rend, 110, 788—799.

THE decolourising properties of charcoal, animal charcoal, resin charcoal, wood charcoal, &c., are generally attributed to the mechanical fixation of the colouring matter in their pores in somewhat the same way that silk takes a dye. The author has made experiments which tend to show that charcoal, and particularly animal charcoal, have powerful oxidising properties. Calcined and washed animal charcoal placed in solutions of  $\alpha$ -naphthylamine or *p*-phenylenediamine developed characteristic colours produced by the oxidation of these bases. Other similar experiments were made with the same result. Charcoal heated in a current of nitrogen and allowed to cool in that gas has much less powerful decolourising properties than the same charcoal allowed to cool in the air. The colour taken up from dark solutions by charcoal cannot be recovered if the action has taken place some hours prior; it is in fact destroyed by oxidation.

—A. L. S.

*The Colouring Matter of Wines.* Monnet. Bull. Soc. Chim. (1889) 2, 144.

MANY metallic sulphides extract the colouring matter from wine like charcoal. As a rule the colouring matter can only be extracted from the sulphides by alcohol acidified with sulphuric acid. In the case of arsenic sulphide, alcohol alone takes up the colouring matter. The alcoholic extract leaves on evaporation a violet colouring matter, soluble in alcohol and glycerol. If the colouring matter is extracted from the sulphide of arsenic by means of alcohol acidified with acetic acid, the residue on evaporation is only partly soluble in alcohol, and if sulphide of lead be substituted for the arsenic, the blue colouring matter obtained is insoluble in alcohol. The author considers it incorrect to suppose the blue colouring matter to be a normal constituent of wine.—J. B. C.

*Automatic Determination of the Density of Sugar Juice.* Spencer's Handbook for Sugar Manufacturers, p. 4.

Having determined the volume of the juice for a stated period, it is necessary to ascertain the total weight, or the average weight of a unit volume. For this purpose the mean specific gravity must be known. This can either be determined automatically or by the chemist. The latter method is perhaps the more certain of giving accurate results, although the apparatus described below is highly recommended by a prominent beet-sugar manufacturer of Germany for the accuracy of its work. If the sampler is used to collect the juice for the chemist's examination for

density, no lead should be employed. A considerable fermentation affects the density determination but little, hence samples may be stored several hours, if necessary, before their examination.

The automatic determination of the density of the juice depends upon the principle of communicating vessels. A column of juice of an invariable height counterbalances a column of water of a height proportional to the density of the juice (see Figure). By means of a suitable connexion, the small reservoir II is connected with the measuring

tank; the juice from each charge drawn into this latter passes through the reservoir and into the tube S, and overflows at *r*. Inside the tube S is another tube F D, which terminates above in a funnel shaped vessel and below in a flexible bulb F. The interior of this tube, including the bulb, is filled with water, whose height is registered upon a cylinder B by means of a float carrying a pencil. It is evident, from an inspection of this apparatus, that the water in the inner tube will rise in proportion to the density of the juice surrounding and pressing upon the flexible rubber bulb. This rise in the level of the water is registered by the pencil, carried by the float, upon the paper-covered cylinder. This cylinder is revolved by clockwork, making one revolution every 12 hours.

The variable temperatures of the juice have no influence upon the apparatus, provided the column of water is of the same temperature as the juice surrounding it. For this reason the tube F is spiral at its lower end. E. Langen, the inventor of this apparatus, has lately substituted a bundle of fine copper tubes for the spiral. Foam and mechanical impurities do not affect the accuracy of the apparatus. The density is recorded in degrees Brix or Baumé, as preferred.

This apparatus may be attached to the upper or lower tank of the measuring apparatus. A double ball valve should be used to admit the juice and prevent overflow and waste.

#### Schmidt's Process for Converting Oleic Acid into Solid Fatty Acids. R. Benedikt. Monatsh. 1890, 11, 71—83.

SOLID fatty acids, such as stearic and palmitic, are separated from liquid fatty acids such as oleic, by pressing the mixed products of the hydrolysis of tallow and palm oil, and used largely in candle making. The liquid fatty acids are a less valuable by-product, and it is therefore desirable to increase the yield of the solid fatty acids as much as possible. It is found that when the sulphuric acid process of saponification is used, the yield is 15—17 per cent.

greater than is obtained by saponification with lime or high pressure steam (*Stas*), and the author has actually found 15.5 per cent. of iso-oleic acid (discovered by Saytzeff, J. prakt. Chem. [2], 37, 269; this Journal, 1888, 442) in a sample of solid fatty acids produced by this method, showing that the oleic acid undergoes isomeric change to this extent (this Journal, 1886, 452).

Various plans have been proposed to enhance this effect but with small success. Elaidic acid is only formed regularly from *fresh* oleic acid by the action of nitrous acid, and besides is a bad material for candles. Neither the conversion of oleic acid into palmitic acid by fusion with caustic alkalis as proposed by Farrentropp, nor its transformation into stearic acid by heating with a small quantity of one of the halogens according to the process of Wilde and Reyhler, is a practical success. Schmidt heats 10 parts of oleic acid with one of zinc chloride to 180° C., washes first with dilute hydrochloric acid, then with water, and distils in a current of superheated steam, pressing the distillate in the usual manner. It is this process which the author has studied. His raw material was a sample of oleic acid made from beef-tallow without admixture of vegetable fats (as these constantly contain linoleic acid), the purity of which was ascertained by its giving the right iodine number and a lead salt completely soluble in ether. Five hundred grms. of it were heated with 50 grms. of zinc chloride in an oil-bath furnished with a thermostat, the temperature being kept at 180°—185° C.—an important condition, as if 195° C. be exceeded no solid product is obtained. Reaction sets in at 180° C., accompanied by slight frothing from the escape of steam, and the zinc chloride speedily dissolves. A drop of the mixture is withdrawn from time to time, boiled with dilute hydrochloric acid, and cooled, and when it becomes solid on cooling the operation is stopped, dilute hydrochloric acid added to the contents of the flask, and the mixture boiled by blowing in steam, the process being repeated until zinc can no longer be detected in the washings, when after a final washing with water, the fatty acids are distilled under a diminished pressure of 120—150 mm., that plan being more convenient than the use of superheated steam when working on a small scale. A greater reduction of pressure is not advisable, as frothing is then apt to occur. The distillate is yellowish-white, and from it is easily separated a white crystalline solid portion by spreading it on a porous tile. The research divided itself into three parts:—

#### I. Investigation of the Washed Product before Distillation.

—A knowledge of the composition of such fatty mixtures is best obtained from the determination of the figures they give for their "acid number," "saponification number," so-called "ether number" (by which is meant the difference between the first two, corresponding to the amount of alkali consumed in saponifying the glycerides present in an ordinary fat), "acetyl number," and "iodine number," rather than by any attempt to isolate their constituents. In this case the mixture was remarkable as containing a notable proportion of what the author terms "unsaponifiable anhydrides," which are only attacked by alcoholic potash when a temperature of 150° C. was reached, and which he considers to consist chiefly of the anhydride of hydroxystearic acid, besides a considerable quantity of "saponifiable anhydride," found to be identical with the *stearolactone* of Geitel, which, though saponifiable, is regenerated as anhydride on being freed by hydrochloric acid, and does not pass into the corresponding acid. From these results, by a close and ingenious chain of reasoning, too long to produce verbatim, and impossible to compress, the author arrives at the conclusion that the composition of the mixture is:—

	Parts per Cent.
"Fluid unsaponifiable anhydride" (the anhydride of hydroxystearic acid).....	8
Stearolactone (the lactone of $\gamma$ -hydroxystearic acid).....	28
Hydroxystearic acid.....	17
Oleic acid.....	40
*Saturated fatty acids.....	7
	<hr/> 100

\* Calculated acid number for these = 193.

**II. Investigation of the Crude Distillate.**—An unsaponifiable portion was present, but instead of consisting of unsaponifiable anhydrides as in I., was found to contain only a small quantity of oxygenated compounds and to be mainly composed of hydrocarbons. The results are:—

	Parts per Cent.
Unsaponifiable matter (fluid) .....	13.6
Oleic and iso-oleic acids .....	43.3
Stearolactone .....	31.0
Saturated fatty acids .....	12.1
	<u>100.0</u>

Determination of the respective quantities of oleic and iso-oleic acid was not practicable, Saytzeff's method giving unsatisfactory results.

**III. Investigation of the Solid Portion of the Distillate.**—Separation of the valuable solid products is effected on the large scale by hot or cold filter pressing, but for experimental purposes the use of a porous tile sufficed. The product was a hard crystalline mass with a melting point of 41°–42° C., which, when examined by the method indicated under I., was found to contain:—

	Parts per Cent.
Stearo-lactone .....	75.8
Iso-oleic acid .....	15.7
*Saturated fatty acids .....	8.5
	<u>100.0</u>

\* Mean molecular weight = 216.

From this it appears that the action of zinc chloride on oleic acid is analogous to that of sulphuric acid; two isomeric addition products with zinc chloride are formed, and these decompose on heating with dilute hydrochloric acid into zinc chloride and two hydroxystearic acids, identical with those found by Geitel to be produced by the action of sulphuric acid on oleic acid (this Journal, 1888, 218). One of these becomes stearo-lactone with elimination of water, the other becoming converted into its anhydride, which is difficultly saponifiable (needing a temperature of 150° C.). A portion of these hydroxystearic acids suffer change on distillation, yielding oleic acid and solid iso-oleic acids, which appear in the distillate as shown above.—B. B.

**The Analysis of Resins and Balsams.** M. Bamberger. Monatsh. 1890, **11**, 84–86.

BENEDIKT and GRÜSSNER, having already published a series of determinations of the "methyl number" of sundry ethereal oils (Chem. Zeit. **13**, 53; this Journal, 1889, 925), the author supplements their observations with those of certain resins and balsams.

Name of Resin or Balsam.	Methyl Number.	Remarks.
Aloes ( <i>Alöe hepatica</i> ) .....	3.9 ..	
Aloes ( <i>Alöe lucida</i> ) .....	0 ..	
Ammoniacum .....	11 ..	Persia.
Asafetida .....	18 ..	
Gum benzoin ( <i>Siam</i> ) .....	28.5 30	
Gum benzoin ( <i>Sumatra</i> ) .....	16.5 16.2	
Gum benzoin ( <i>Sumatra</i> ) ( <i>Almond</i> ) ..	13.3 ..	
Bellium .....	0 ..	Africa.
Canada balsam .....	0 ..	
Copaiba balsam .....	0 ..	
Copal .....	0 ..	Zanzibar.
Colophony .....	0 ..	
Gum dammar .....	0 ..	
Dragon's blood .....	33.8 ..	Sundainsel.

Name of Resin or Balsam.	Methyl Number.	Remarks.
Euphorbium .....	0 ..	Africa.
Gum elemi .....	0 ..	
Resin ( <i>Pinus taeda</i> ) .....	0 ..	
Resin ( <i>Pinus halepensis</i> ) .....	0 ..	South Austria.
Resin ( <i>Pinus laricio</i> ) .....	49.6 50.9	
Galbanum .....	3.7 4.0	
Gamboge .....	0 ..	Lower India.
Guaicum .....	83.8 84	
Jalap .....	0 ..	
Kauri dammar .....	7.1 ..	
Ladanum .....	0 ..	
Liquidambar .....	0 ..	
Myrrh .....	13.6 13.2	
Mastic .....	0 ..	
Olibanum ( <i>Frankincense</i> ) .....	5.3 ..	Africa.
Oppoponax .....	9.9 ..	Asia Minor.
Balsam of Peru .....	14.4 ..	
Storax calamitus .....	0 ..	Asia Minor.
Scammony .....	0 ..	Smyrna.
Sandarac .....	0 ..	Asia Minor.
Shellac .....	0 ..	
Tacamahac .....	0 ..	
Venice turpentine .....	0 ..	
Balsam of Tolu .....	46.8 ..	
Xanthorrhoea resin ( <i>Yellow</i> ) .....	26.4 ..	
Xanthorrhoea resin ( <i>Red</i> ) .....	32.7 ..	

The numbers in the third column are those of duplicate determinations.

B. B.

**Volumetric Estimation of Tannin.** E. Guenz. Compt. Rend. **110**, 532–534.

A STANDARD solution is made of tartar emetic, 12 grms., and Poirier's green 4.16, 1 gm., to 1 litre of distilled water. The solution of tannin to be estimated is placed in a burette and run into 20 cc. of the boiling standard coloured liquid until complete decolouration just occurs. The standard solution is titrated against a solution of pure oak gall tannin of known strength. Gallie acid does not interfere with this process.—J. M. H. M.

**The Estimation of the Tannic Acids in Sumac.** L. Bruehl. See under VI., pages 607–608.

**Estimation of Acetone in Wood Spirit.** L. Vignon. Compt. Rend. **110**, 534–536.

IN applying Krämer's process, founded on Lieben's iodoform reaction, to the determination of the acetone present in the crude methyl alcohol used for the preparation of methylated spirit, it is necessary to have the iodine present in large excess, and to conduct the operation in the following way: 5 cc. of the wood spirit are dissolved in 200 cc. of distilled water, and the volume made up to 250 cc.; 5 cc. of this mixture are placed in a stoppered and graduated cylinder with 10 cc. of binormal soda and, after shaking, 5 cc. of binormal iodine are added, and the mixture again shaken; 10 cc. of ether free from alcohol are then added to take up the iodoform, and the volume of the ethereal solution noted.

5 cc. of the ethereal solution are pipetted off and evaporated in vacuo, and the iodoform weighed as soon as possible.  $\text{CHI}_3$  corresponds to  $(\text{CH}_3)_2\text{CO}$ . Aldehyde, ethyl alcohol, and other bodies capable of furnishing iodoform must be absent (see following abstract).—J. M. H. M.

*Estimation of Acetone by Iodoform.* E. Arachequesne. *Compt. Rend.* **110**, 642—644.

KRÄMER'S method (see preceding abstract) for the estimation of acetone, based on Lieben's reaction, was intended only for determinations in methyl alcohol, used in the manufacture of methylaniline, containing, at most, 1 per cent. of acetone. With a view to making the method generally useful, the author makes the following proposals:—1. That Krämer's method, as it is, should be used only with pure methyl alcohol. 2. When the liquid to be analysed contains 1·5 to 30 per cent. of acetone, a smaller amount should be employed. For example, with liquids containing 20 to 30 per cent. of acetone, take 5 cc., dilute with water to 500 cc. and of the diluted solution take 5 cc. for the analysis, and multiply the result by 20. 3. With solutions still richer in acetone, 5 cc. is diluted with water to 50 cc. Of this solution 5 cc. is put into a 200 cc. flask, the bottom of which terminates in a point closed with an india-rubber tube and a clamp. Binormal soda (10 cc.) and binormal iodine solution (5 cc.) are added, and the whole shaken. The addition of the soda and iodine solutions (in the same proportions) is then continued until no more iodoform is precipitated. The iodoform is then washed into a burette, having a plug of asbestos at the bottom, and after the excess of solution has run through, is dissolved in ether and weighed as described by Krämer.—N. H. J. M.

*Estimation of Fat in Milk.* Lezô. *Compt. Rend.*, **110**, 647—649.

THE separation of fat in milk is hindered by the casein which retains the globules of butter. The difficulty is overcome by dissolving the casein in acid. The milk is shaken with strong hydrochloric acid (2 to 2·5 parts) and poured into a flask with a long neck graduated in cc. and tenths of cc. It is then heated until the liquid becomes brown, treated with dilute ammonia until the oil is completely separated, and hot water added until the water level reaches the graduated neck of the flask. The volume of melted fat is then read and the number of cc. multiplied by 0·90 (the specific gravity) gives the weight in grms. This correction may be avoided by taking, for instance, 110 cc. of milk instead of 100 cc.; the number of cc. of fat then represents grms. per cent. 44 cc. of milk and 100 cc. of acid are convenient amounts to employ. The mixture is heated to about 80°.

—N. H. J. M.

*The Analysis of the Methylanilines.* H. Giraud. *Bull. Soc. Chim.* 1889, **2**, 142—144.

THE method is based upon that of Reverdin and de la Harpe (this Journal, 1889, 422), and consists in adding acetic anhydride to methylaniline and determining the amount of acetic acid formed. The author, however, instead of employing acetic anhydride alone, employs a mixture of the anhydride with 10 times its volume of dimethylaniline. This mixture keeps better than the anhydride, and the dimethylaniline has no influence on the reaction. The solution is titrated against a standard solution of baryta, litmus or phenol phthalein being used as indicator. The analysis is conducted in the following manner. 1 gm. of the mixed methyl anilines and 10 cc. of the anhydride mixture are brought together in a flask, which is closed with cork. After an hour water is added and the liquor titrated with baryta. The difference between the first and second titration gives the amount of methylaniline or aniline present.—J. B. C.

*On Benedikt's Acetyl Values.* J. Lewkowitsch. *Proc. Chem. Soc.* 1890, 72—74; also 91—92.

IN his paper on a new method of examining fats (*Zeits. für die Chem. Ind.* 1887, 148), Benedikt proposes a method

which is based on the principle that only hydroxylated fatty acids take up the radicle of acetic acid when heated with acetic anhydride, and he asserts that those fatty acids which do not contain the hydroxyl-group remain unaltered; so that the quantities of potash required for neutralising fatty acids before and after treatment with acetic anhydride will be either identical or nearly so, any difference being due to the errors of the method of determination.

While examining a somewhat abnormal sample of tallow, the author was led to doubt the accuracy of this statement, and the following results of experiments which he has made serve to confirm his doubts.

The fatty acids prepared from a sample of fresh town tallow required for neutralisation 19·717 per cent. of potash, or, in other words, their "acid value" was equal to 19·717, corresponding to the molecular weight 284·5. 50 grms. of these acids was acetylated with 40 grms. of acetic anhydride in the manner indicated by Benedikt, and both the acid value and the "saponification" value of the acetylated product was then determined. The values found were 160·5 and 217·5 respectively, corresponding to an acetyl value of  $217·5 - 160·5 = 57$ . A second test gave  $216·3 - 159·9 = 56·4$ .

In the same way the fatty acids of samples of South American tallow and of North American tallow gave the acetyl values 77·8 and 23·93. According to Benedikt the acetyl values ought to have been *nil* or nearly so.

As tallow is considered to consist essentially of a mixture of the glycerides of stearic, palmitic, and oleic acids, it was thought possible that it was the oleic acid which had fixed the acetic acid radicle. A sample of oleic acid obtained from Kahlbaum as pure was therefore examined; it contained, however, some solid acids, which settled out when the acid was kept for some time in a stoppered bottle. To determine the impurities, the acid value and iodine absorption were ascertained: the acid value found was 183, and the iodine absorption 90·14; the theoretical values for oleic acid are 198 and 90·07. Although containing a certain amount of higher homologues, the acid was considered sufficiently pure for the desired purpose: 50 grms. of it when acetylated gave an acid value = 116·50 and a saponification value = 242·05; consequently an acetyl value = 125·55. If the fixing of the "acetyl," however unlikely it might appear, were due to the  $\text{CH}_2\text{CH}$ -group in the molecule of the oleic acid, the acetylated acids ought to have lost the capacity of taking up iodine. However, the iodine value of the acetylated acids was found to be 87·11, proving clearly that acetyl was not taken up by the  $\text{CH}_2\text{CH}$ -group. Therefore, the acetic anhydride must have acted in some other way on the oleic acid, and if so it was not unlikely that palmitic or stearic acid might be acted on in the same way. Experiment fully bore out the correctness of this assumption.

Fifty grms. palmitic acid, the comparative purity of which was proved by an acid value of 213·4 (instead of the theoretical value 219·1), were acetylated and gave an acid value = 143·53 and a saponification value = 226·13; consequently an acetyl value = 82·6.

Fifty grms. stearic acid—showing an acid value of 203 instead of the theoretical one of 197·5—gave, after being acetylated, an acid value = 138·89 and a saponification value = 221·18; consequently an acetyl value = 82·29.

These results were so unexpected that it was determined to verify them by examining other fatty acids: capric, lauric, and erotic acids were therefore acetylated in the manner previously stated. The approximate purity of the acids used was ascertained by determining the quantity of caustic potash required for their saturation.

*Capric Acid.*—The acid value was found to be 318·65, while theory requires 326·2. The acetylated product gave an acid value of 176·4, and a saponification value of 350·4; consequently an acetyl value = 174.

*Lauric Acid.*—The acid value found was 273·02, the theoretical value being 280·5. The acetylated acid gave an acid value = 161·5, a saponification value = 293·99; its acetyl value therefore was 132·49.

*Cerotic Acid.*—The acid value found was 128·4; theory indicates for  $\text{C}_{26}\text{H}_{52}\text{O}_2$  141·6 (or for  $\text{C}_{27}\text{H}_{54}\text{O}_2$  136·8). The

acetylated cerotic acid gave an acid value = 73.87, a saponification value = 142.1; so that the acetyl value was 68.23.

From the approximate coincidence of the acetyl value of capric acid (174) with the acid value of the acetylated acid (176.4), it might be inferred that the acetylated capric acid contains one acetyl-group, but an acid of the formula  $C_{16}H_{31}O_2 \cdot C_2H_5O$  has a theoretical acid value of 262. Similarly the value for a mono-acetyl derivative of lauric acid would be 231, and that for a mono-acetyl derivative of cerotic acid 128 (or otherwise 124). (The same formulae would apply to mixed anhydrides of acetic acid and capric acid, &c.) It was easy to decide whether the action of acetic anhydride on fatty acids affected the  $COOH$  group of the latter, for in that case an alcohol of the  $C_nH_{2n+2}O$  series ought not to become acetylated. The author experimented on cetyl alcohol, which was treated with acetic anhydride. The acid value of the resulting substance was—as is to be expected—*nil*; the saponification value found was 192.65. As a substance of the formula  $C_{16}H_{33}O \cdot C_2H_5O$  has theoretically a saponification value = 198, it is evident that simply etherisation of the cetyl alcohol has taken place.

It was therefore to be supposed, as the mixed anhydrides of the higher fatty acids and acetic acid could not have been formed, that by the interaction of acetic anhydride and the higher fatty acids the anhydrides of the latter had been produced—taking palmitic acid as an example—according to the following equation—

In that case the quantities of caustic potash required by the equation  $(C_{16}H_{31}O)_2O + 2KOH = 2C_{16}H_{31}O \cdot OK + H_2O$  ought to agree with the saponification values found. The following table gives the quantities of caustic potash required by theory, in milligrammes, compared with the quantities actually used in the above experiments:—

	Mol. wt.	Theory.	Expt.
Capric anhydride $(C_{10}H_{19}O)_2O$ ....	326	344	350.4
Lauric anhydride $(C_{12}H_{23}O)_2O$ ....	242	294	293.90
Palmitic anhydride $(C_{16}H_{31}O)_2O$ ..	494	227	226.13
Stearic anhydride $(C_{18}H_{35}O)_2O$ ....	550	204	221.18
Cerotic anhydride { $C_{26}H_{51}O)_2O$ ...	774	145	} 112
	$C_{27}H_{53}O)_2O$ ...	818	137
Oleic anhydride $(C_{18}H_{33}O)_2O$ ....	546	205.4	242

Considering the approximate purity of the acids used, the theoretical values agree very well with the experimental values, and it may be pointed out that with pure material it would be easy by this method to determine which is the formula of cerotic acid.

In the light of this explanation, the "acid values" found for the products of the interaction of acetic anhydride and fatty acids lose every quantitative meaning; as the "acetylated" acids were dissolved in cold absolute alcohol for titration with potash, which at once hydrolysed the anhydrides, hydrolysis ceasing only when a limit was reached which depended on the quantity of alcohol present, and the nature and dilution of the standard solution—in some experiments half normal soda, in others decinormal potash. Had the substances been shaken up with water (hot water does not decompose them), on the first drop of potash falling into the mixture the pink colour would have appeared at once, or very soon when the limit for the system of substances was reached. Experiments carried out in this direction fully bear out the correctness of the author's conclusions. Thus the interaction of  $KOH$  or  $NaOH$  and the anhydrides in aqueous solution affords an elegant illustration of that class of actions which require a measurable time for their completion. The anhydrides of the higher fatty acids are now within easy reach, as they can be prepared in a very short time by means of acetic anhydride.

## ERRATUM.

In the May number of this Journal, page 557, line 7 from top of column 1, for "very oxidisable bodies" read "not very oxidisable bodies."

## New Books.

A TREATISE ON CHEMISTRY. By SIR H. E. ROSCOE, F.R.S., and C. SCHORLEMMER, F.R.S. Vol. III.—The Chemistry of the Hydrocarbons and their Derivatives, or Organic Chemistry. PART II.—New and thoroughly revised edition. London and New York: Macmillan and Co. 1890.

The first appearance of this part of Roscoe and Schorlemmer's great work was in 1884. Since that time the knowledge respecting this department of Organic Chemistry has largely increased. In the present volume will be found, for example, the researches of Curtius on the fatty diazo-compounds; of Kiliani on the constitution of the members of the sugar group; of Emil Fischer on the artificial production of certain members of this group; of Brown, Heron, and Morris on the starches and dextrins; and further, of W. H. Perkin, junr., on the Polymethylene compounds, all this being fresh matter since 1884. These enlargements and additions have made it necessary to defer the consideration of the derivatives of Furfuran, Pyrrol, and Thiophen for another volume, together with the Pyridine and Quinoline derivatives. The price of the volume is 21s. (See this Journal, 1884, 331.)

DIE VERUNREINIGUNG DER GEWÄSSER, EINE DENKSCHRIFT IM AUFTRAGE DER FLUSS-COMMISSION DES VEREINS ZUR WAHRUNG DER INTERESSEN DER CHEMISCHEN INDUSTRIE DEUTSCHLANDS. Bearbeitet von DR. KONRAD WILHELM JURISCH. Privat-Dozent an der königlichen Technischen Hochschule, Berlin. 1890. Berlin: R. Gaertner's Verlagsbuchhandlung. Hermann Heyfelder, S.W. Schönebergerstrasse 26. London: H. Grevel and Co., 33, King Street, Covent Garden.

A QUARTO volume, containing 110 pages of Subject-Matter, Preface, Table of Contents, and Alphabetical Index. The price is 10s. The work is stated to furnish a complete and clear treatise on all the details relating to the Removal of the Waste Waters and Liquors from Works. The following excerpt of the contents of the work will give the clearest idea both of its contents and the nature of the treatment of the subject:—

PART I.—Description of the Waste Liquors or Waters. (1.) Sewage and Waste Waters in Town and Country. (2.) Waste Matters and Waters of Domestic Trades and Mechanical Industries. (3.) Waste Waters of Mining and Metallurgical Industries. (4.) Waste Waters of the Agricultural and Chemical Industries.

PART II.—On the Damage done by Waste Waters and Liquors as they go forth from the Works and Factories. (1.) Waste Liquors containing Nitrogenous Organic Impurities. (2.) Waste Liquors with Solids in suspension. (3.) Waste Liquors with predominating Mineral Matters. Conclusions.

PART III.—The Purification of Waste Waters. (1.) Sewage or Waste Waters containing Nitrogenous Organic Impurities. (2.) Waste Waters containing Solids in suspension. (3.) Waste Waters with predominating Mineral Matters.

PART IV.—The German Rivers.

PART V.—Contaminated River Water.

PART VI.—The Fishery Interests. (a.) The Effects of Sewage and Waste Liquor Contamination on the Fisheries. (b.) An Exposition of other Injurious Influences on the Fisheries.

PART VII.—Importance of the Fishery Question.

PART VIII.—Judgment on the Sewage and Waste Water Question.

PART IX.—Dealing with the Sewage and Waste Water Question.

PART X.—Influence of the Waste Liquors of Works on the Health of the People in the adjacent regions.

PART XI.—Conclusion.

A TECHNOLOGICAL DICTIONARY OF INSURANCE CHEMISTRY. By WILLIAM A. HARRIS, F.R.S.S.A., &c. &c., 1890: Published by the Author, Phoenix Fire Office, Phoenix Chambers, Exchange, Liverpool.

OCTAVO volume, bound in red cloth, and containing, besides preface and introduction, 407 pages of subject matter. Price 21s. The work is described by the author as a "Compendium of the latest information on subjects of vital importance to insurance managers, surveyors, underwriters, government officials in all countries, merchants, captains, shippers, harbour-masters, &c., and home, colonial, and foreign insurance agents; explaining the various risks to be apprehended from spontaneous combustion, oxidation, chemical affinity, fermentation, friction, expansion of gases, inflammability of vapours, dust explosions, steam-heating and drying, oils, fibres, coal, cotton, and mixed cargoes, &c., &c. With actual cases showing where losses have occurred, &c."

The work may be defined as a technological chemical and physical dictionary with special reference to the various causes of superheating, fires, and explosions.

THE PATENTEE'S MANUAL. A Treatise on the Law and Practice of Patents for Inventions, with an Appendix of Statutes, Rules, and Foreign and Colonial Patent Laws, International Convention and Protocol. By JAMES JOHNSON, of the Middle Temple, Barrister-at-Law, and J. HENRY JOHNSON, Solicitor, Assoc. Inst. C.E., &c. Sixth Edition, revised and enlarged. 1890. London: Longmans, Green, and Co., Paternoster Row; Stevens and Sons, Lim., 119 and 120, Chancery Lane.

The fifth edition of this work (see New Books, this Journal 1884, 654) contained 489 pages. The present edition contains 534 pages, and its price is 10s. 6d. Amongst the improvements introduced are the following:—"The provisions of three supplementary Acts of Parliament and of four new sets of Official Rules, now consolidated with the previous Rules, have been noticed, whilst numerous decisions of the Courts during the last six years, many of which have had an important bearing on the Law of Patents, have been cited." "Great additions to and alterations in the Patent Laws of Foreign States and British Colonies have been made of recent years. The Appendix contains summaries of the whole of those laws to date," duly revised in those States or Colonies.

It is stated at the close of the Preface, that "the number of applications for patents increases at the rate of about a thousand a year."

TREATISE ON THE EVAPORATION OF SACCHARINE, CHEMICAL, AND OTHER LIQUIDS BY THE MULTIPLE SYSTEM IN VACUUM AND OPEN AIR, ALSO THE CONSTRUCTION AND WORKING OF THE DIFFERENT SYSTEMS. By JAMES FOSTER, M.I.M.E. Sunderland: Thomas Reed and Co. London: Simpkin, Marshall, and Co.; Hamilton, Adams, and Co. London and New York: E. and F. N. Spou. Glasgow: George Routledge and Sons; W. and R. Holmes. Amsterdam: J. H. de Bussy.

This is an octavo volume, bound in red cloth, containing 600 pages of Subject-matter and 123 pages of Matter consisting of the text of 12 patents. The illustrations or diagrams number 195, and there are 49 large plates. With the text are interspersed 56 tables relating to the matter thereon. The price is 21s. The work is a systematic complement of all of importance that has been done in the direction indicated in modern times, and in his preface the author says its purpose is, "to supply a long felt want for the Industries where Evaporation is required, in which both makers and users are interested." At the end of the treatise is to be found an account of the sugar machinery used in the West Indies up to the year 1848, which the author has reproduced from Leonard Wray's work, entitled "The Practical Sugar Planter," of that date, to show the strides made in the evaporation of sugar juices during the last 40 years.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

#### RUSSIA.

##### Classification of Articles in Customs Tariff.

Mr. J. Michell, Her Majesty's Consul at St. Petersburg, in a report to the Foreign Office, dated the 26th May, encloses decisions of the Russian Department of Customs, to the effect that the under-mentioned articles are classified as follows under the Russian tariff:—

Coal, slag, produce of blast furnaces, reduced to powder, under section 18 of the tariff, as a manuring substance. Duty free.

Phosphorite dust, similarly as bone dust, to be exported from Russia, under section 1 of tariff of exportable goods. Duty free.

Limestone to be cleared similarly as chalk in pieces not purified and not calcined, under section 7, point 1. Duty free.

#### SWITZERLAND.

##### Classification of Articles in Customs Tariff.

Note.—Quintal = 220·4 lb. avoirdupois. Franc = 9<sup>6</sup>/<sub>10</sub>d.

The following decisions affecting the classification of articles in the Swiss Customs tariff have recently been given by the Swiss Customs authorities:—

Sulfocyanure of aluminium.—Category 17. Duty, 1 franc per quintal.

Sulphurous acid compressed, which was formerly in Category 9a, is now classified in Category 18, and pays a duty of 2 francs per quintal.

Grape-sugar (glucose) in the form of syrup.—Category 243. Duty, 7 francs per quintal.

Grape-sugar (glucose) in a solid state.—Category 244. Duty, 7 francs 50 cents. per quintal.

## ITALY.

*The Treatment of Saccharine and its Products.*

The Marquis of Dufferin and Ava, Her Majesty's Ambassador at Rome, in a despatch to the Foreign Office, encloses translations from the *Italian Gazette* of decrees of the King of Italy on the treatment of saccharine and saccharine products.

Decree No. I. provides that the Royal decree of 26th July 1888, by which various changes were introduced into the general Customs tariff, respecting the duty to be paid on the importation of acetic acid, saccharine, and other chemical products not specified, is converted into law.

By decree No. 11., the Royal decree of 29th September 1889, which forbids the introduction or production within the kingdom of saccharine and saccharine products is converted into law.

## UNITED STATES.

*Recent Customs Decisions.*

Certain terra-cotta paste and powder, not a dye-wood extract, but a composed colour, one portion being derived from a vegetable source, and the other from alizarine, either of vegetable extraction or of coal-tar origin, is dutiable at the rate of 25 per cent. *ad valorem*.

Certain so-called "Eikonogen" not an auiline salt, nor an acid, nor a preparation of coal-tar, but a chemical compound, possibly derived from a preparation of coal-tar, is dutiable at the rate of 25 per cent. *ad valorem*.

Certain chlorophyll found on chemical analysis to be a vegetable colour which is principally used in colouring soap, is dutiable at the rate of 25 per cent. *ad valorem*.

Thio-chromogen, a coal-tar colour, is dutiable at the rate of 35 per cent. *ad valorem*.

Certain so-called "Cherry Laurel" is dutiable as medicinal waters, non-alcoholic, at the rate of 25 per cent. *ad valorem*.

## VICTORIA.

*New Customs Tariff.*

The following is a statement of the rates of Customs duty now levied on the importation of articles into the colony of Victoria. The modifications which form the basis of this new tariff were published at pp. 268—75 of the March issue of the *Board of Trade Journal*:—

Classification of Articles.	Rates of Duty now levied.
	£ s. d.
Acids, viz.:	
Acetic, containing not more than 30 per cent. acidity.....	Pt. or lb. 0 0 3
Acetic, for every extra 10 per cent. or part of 10 per cent. above 30 per cent. ....	" 0 0 1
Muriatic, nitric, sulphuric .....	Cwt. 0 5 0
Butterine and oleomargarine .....	Lb. 0 1 0
Candle nuts .....	Free.
Candles.....	Lb. 0 0 2
Charcoal and coal (ground).....	20 % <i>ad val.</i>
Charcoal, animal (ground) .....	Free.
Drugs, viz.:	
Ammonia, carbonate of .....	Pt. or lb. 0 0 2
" liquid.....	" 0 0 2
Chlorodyne .....	25 % <i>ad val.</i>
Cocculus indicus.....	Lb. 0 1 0
Glycerin, pure.....	" 0 0 3
" crude.....	" 0 0 1
Morphia.....	Oz. 0 1 6

Classification of Articles.	Rates of Duty now levied.
	£ s. d.
Drugs— <i>cont.</i>	
Nitrate of silver .....	Oz. 0 0 6
Nux vomica .....	Lb. 0 0 2
Strychnine .....	Oz. 0 1 0
Explosives (except fine meal powder, not sporting, in bulk and in packages of not less than 25 lb. each), viz.:	
Powder, sporting.....	Lb. 0 0 3
" blasting .....	" 0 0 1
Gelatin and gelatin dynamite .....	" 0 0 1
Other explosives.....	" 0 0 4
Gelatin .....	" 0 0 6
Leather (except crust or rough tanned, viz. :— Calf, goat, hogskin, sheep, or kangaroo, when not exceeding seven pounds each skin; and English bend, sometimes called butt).....	" 0 0 6
Do., viz. :—Kid, calf kid, mock kid, and patent calf.....	Free.
Do., being furniture and bookbinding Morocco, roan, and pasto grain skiver.....	Lb. 0 1 0
Medicines, consisting of two or more ingredients mixed ready for use, not being in chemical combination, drugs and chemicals, packed ready for retail sale or for consumption, including medical compounds containing spirits not exceeding the strength of proof by Sykes' hydrometer; and all preparations recommended as beneficial for any portion of the human or animal body, or the cure or the treatment of any disease or affection whatever, and medicine chests or cases, with or without fittings.....	25 % <i>ad val.</i>
Oils, in bulk (except coconut, fish of all sorts, mineral, refined, of which the point of ignition is below 80° F., kerosene, palm, lubricating, of which the chief component part is mineral; and resin).....	Gall. 0 0 6
Do., viz., resin.....	Free.
Do., kerosene .....	Gall. 0 0 6
Do., packed in bottles, jars, or other vessels not exceeding one gallon in size, as under:	
Quarts and over a pint .....	Doz. 0 4 0
Pints and over half a pint .....	" 0 2 0
Half pints and smaller sizes.....	" 0 1 0
Over a quart and not exceeding a gallon..	" 0 12 0
Opium, including all goods, wares, and merchandise mixed or saturated with opium or with any preparation or solution thereof, or steeped therein respectively .....	Lb. 1 0 0
Paints and colours (except artists' colours): Ground in oil, including patent dryers and putty .....	Ton 2 0 0
Mixed, ready for use, from or of any substance .....	" 4 0 0
Perfumery.....	20 % <i>ad val.</i>
Powders, baking, scidnitz, washing .....	20 % <i>ad val.</i>
Salt (except rock salt) .....	Ton 1 0 0
Soap, perfumed, and toilet .....	Lb. 0 0 4
Do., other.....	" 0 0 2
Soda crystals .....	Ton 2 0 0
Spirits, cordials, liqueurs, or strong waters, sweetened or mixed with any article so that the degree of strength cannot be ascertained by Sykes' hydrometer (including all alcohol diluted or undiluted with water or other menstruum and containing in solution any essence, essential oil, ether, or other flavouring or other substance whether of natural or artificial origin).....	" 0 12 0

Classification of Articles.	Rates of Duty now levied.
Spirits, methylated .....	Liq. gall. $\begin{smallmatrix} £ & s. & d. \\ 0 & 1 & 0 \end{smallmatrix}$
Do., perfumed .....	Gall. 1 4 0
Spirits mixed with essential oils, so as to be unfit for human consumption, to be used in the manufacture of soap, under Commissioner's permit, provided the mixing is performed in the presence of an officer of Customs.....	Free.
Starch.....	Lb. 0 0 2
Stearin .....	" 0 0 2
Sugar, the produce of sugar cane.....	Cwt. 0 3 0
Sugar, the produce of sugar cane, bonded on and after 27th day of July 1887, and refined in Victoria in a bonded warehouse, under regulations to be framed by the Governor in Council.....	" 0 2 0
Sugar, the produce of beetroot and all other sugar.....	" 0 6 0
Sugar candy.....	Pt. or lb. 0 0 2
Sugar molasses (except unrefined) .....	Cwt. 0 3 0
Varnish (including lithographic) .....	Gall. 0 2 0
Vinegar, not being acetic acid or crude vinegar, aromatic, or raspberry .....	" 0 0 6

## EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

### NITRATE TRADE OF CHILI.

Report by Consul-General Walker, of Bogota.

#### Geographical Position of the Nitrate Deposits.

The chief deposits of the crude nitrate of soda are found in the province of Tarapacá, formerly a part of Peru, but ceded to Chili in 1881 as a war indemnity on condition that after 10 years it may be restored to Peru, provided a majority of the voting population of the province shall so elect, and upon the payment to Chili of 10,000,000 dols. Upon such conditions it is not probable that this territory will ever revert to its former owner; for, in addition to the money difficulty, a serious one in the present disorganised condition of Peruvian finances, the large accessions of population to Tarapacá since its annexation to Chili have been mostly from that Republic, and these new-comers will naturally be averse to restoration.

The province of Antofagasta, acquired by Chili from Bolivia, and joining Tarapacá on the south, and having similar geological and climatic features, is also rich in nitrate deposits. A point a few miles south of Taltal, in this province, in latitude 25° 45' S., may be considered the southern limit of the nitrate belt, its northern being in latitude 19° 12' S.; its extreme north and south length being thus shown to be 260 geographical miles. Its average width is not more than 2½ miles. This narrow strip of nitrate lands stretches along the eastern slope of the coast range of barren, verdureless mountains which wall in the Pacific Ocean, from the northern limit of Peru, to the Straits of Magellan, upon which, for more than 2,000 miles, not a drop of rain ever falls, and upon which there is not a tree, shrub, or any living vegetation. Some of its peaks reach an altitude of 4,000 or 5,000 feet above the sea level, but the usual height of the range is about 2,000. The average distance from the coast to the nitrate beds is about 14 miles, but many of them are not more than 10.

The following profile will give a better understanding of the situation of these deposits:—

A, Pacific Ocean; B, coast range; C, location of nitrate deposits; D, valley of Tamagruel; E, beginning of the main cordillera of the Andes.

#### Nitrate Development.

As early as 1813 some effort had been made to develop these nitrate deposits. During that year the Spaniards exported 22,732 quintals; but, the war of independence breaking out about that time, little was done to develop these mines of wealth until 1852. During that year an Englishman, George Smith, and José Sandes, a Spaniard, established small refining works at Iquique, under the name of the Tarapacá Nitrate Company. Encouraged by their success, numerous other similar establishments sprung up at different points along the coast, and by the year 1875 the nitrate trade had attained so important a development as to attract the attention of the Peruvian Government to it as a source of national revenue. In that year a law was passed providing for the acquisition of the nitrate deposits and refining establishments by the favourite method of "expropriation," and more than 60 different properties, belonging to companies and individuals, were taken possession of by the Peruvian authorities. Certificates were given in payment, to be redeemed through bills of exchange on London, drawn against shipments of nitrate.

The war with Chili broke out before any material portion of this indemnity was paid; but, as the owners of the expropriated property had been fully dispossessed, Chili, during the progress of the war, took possession of it as national Peruvian property. At the end of the war the outstanding certificates issued by Peru, principal and interest, were found to amount to 5,400,000l. (26,276,400 dols.) Chili, having fallen heir to the property, was morally bound to satisfy all mortgages and liens upon it, or to restore it to its original owners. After a few years of unsatisfactory experience in carrying on nitrate production for Government account, she wisely determined to adopt the latter alternative, and on 11th June 1881, the President of the Republic issued a decree ordering the restoration of the expropriated nitrate properties to their original owners. The conditions of this restoration were the delivery to the Chilean Government of a minimum of three-fourths of the certificates in amount given by Peru to the dispossessed owners, and a deposit of money, equal in amount to that of the deficient certificates, to be returned upon the delivery of the latter.

This wise and just measure gave an immediate and powerful impulse to nitrate production, and has proved a very advantageous arrangement for the Chilean treasury. It has not, however, been unattended with some disadvantages and dangers to the commercial prosperity of the Republic. The English companies, organised under the policy of restoration, are making strenuous efforts to secure a monopoly of the nitrate trade. Success in these efforts would signify diminished production to secure high prices, a large falling off of Government revenue from exports, and the ruin of small operators, who now contribute so largely to the aggregate of nitrate production and to the prosperity of the Republic. This is no idle fear, and doubtless the Chilean Government is alive to the danger.

The London nitrate companies, and the fabulous fortunes so suddenly acquired by their skilful manipulations, had their origin in this policy of restoration. Their history is not without interest.

During the short and unsatisfactory experiment made by Chili in carrying on nitrate production for Government account, an Englishman was employed as nitrate inspector, who, by means of his official connexion with the Government, ascertained, it is said, its intention in favour of the ex-owners of nitrate properties long before the public had any such knowledge. Forming a combination with another Englishman, whose name has since become widely known in connexion with the nitrate trade, and with still another

Englishman, the manager of a Valparaíso bank, the combination hastened to Lima, where the Peruvian certificates were mostly held, and succeeded in purchasing, it is said, for less than half their face value, certificates which carried with them the right of redemption of eight or ten of the most valuable of the nitrate properties in the whole province of Tarapacá. For instance, they acquired the property of the Ramírez Company, it is said, for 5,000*l.*, and afterwards sold it in London for 50,000*l.* In this way, and at corresponding prices, they secured the "Peruana," the "Bien Retiro," the "Jaspampa," the "Virginia," and others—the very cream of the Iquique and Pisagua properties. Upon the success of these purchases the combination transferred their operations to London, and within the last six years have floated eight stock companies (limited), with an aggregate capital of 5,875,000*l.* (28,587,750 *dols.*), the shares of which, it is believed, are still largely held by themselves. The splendid showing of profits which they made enabled them to put the stock of these companies on the market at a high rate, notwithstanding the enormous figures at which they were capitalised; and these prices have been well maintained. I have no recent quotations at hand, but I am informed that in most, if not all, of these companies their shares still command a high premium.

In addition to the English companies above alluded to which have a substantial basis in valuable nitrate properties, several self-named nitrate companies have been organised in London, with enormous nominal capital, which are purely speculative, being based on neither Government concessions nor the ownership of nitrate or other property in Chili. To what extent their promoters have succeeded in abstracting sovereigns from the pockets of credulous investors I cannot say.

The wise and liberal policy of the Chilean Government in encouraging small and independent establishments is an obstacle to the formation of a monopolistic "trust" or combination of the English companies, for the control of the nitrate trade.

At the time of my recent visit to Chili as special commissioner a large and imposing representation of these companies arrived at Santiago for the purpose, it was said, of obtaining such concessions and changes in nitrate regulations as would render them masters of the situation and give them a virtual monopoly of the nitrate trade. How far they succeeded in their designs I have no positive information, but I am convinced that the policy of strengthening the hands of the would-be monopolists was fully appreciated at Santiago. On the other hand, I am convinced that the investment of American capital in the nitrate business of Chili would be favourably regarded by both Government and people as tending to impose a wholesome obstacle and check to the monopolistic tendencies of the English companies, which may be considered *pro tanto* under one management.

#### *The Nitrate Deposits.*

The possibility of so strange a fact as the existence in open air of enormous deposits of a salt so deliquescent and easily destroyed by moisture as the nitrate of soda, is partially accounted for by the strange meteorological fact that where they are found it never rains. This rainless region extends from the northern part of Peru, in about south latitude 4°, to about latitude 30° S, and inland from the shores of the Pacific to the main cordillera of the Andes, an average distance of about 90 miles. The country within these limits is a perfect desert, except along the borders of the few streams which, rising in the snow mountains, force their way into and across the desert to the Pacific, furnishing along their course water for irrigation, such as the river Rimac, which runs through the centre of the city of Lima, and irrigates the broad fruitful valley lying between that city and the sea coast.

I have already explained that the nitrate beds are found on the eastern slope of the coast range, which, often precipitous on its western face, on its eastern slopes gently down to the valley of Tamagruel, which separates the coast range from the main cordillera of the Andes. This valley, with an average width of 10 miles, stretches from the hills of Caricoles, which connect the two Andean ranges, in

latitude 22° 40' S., to Aguas Blancas, in latitude 25° 45', south of which point the country becomes very broken, and the nitrate deposits disappear.

This valley is wholly devoid of all the characteristics which we usually associate with the word, such as groves of green trees, verdant pastures, running streams, &c. Instead, the eye wanders over a scene of treeless, verdureless, waterless desolation. It is true, on the eastern side of the valley there is found an occasional weak spring, where feeble attempts at cultivation have been made, but with indifferent success, as the soil is so thoroughly impregnated with salts of various kinds as to render its profitable cultivation impossible, even with a sufficiency of water for irrigation.

The point on the slope of the mountain where the deposits of caliche are found is some 500 or 600 feet higher than the valley, but it diminishes in quantity and richness as the valley is approached, and disappears entirely at the bottom.

An examination of the workings of these beds discloses the following conditions:—

(1.) That the surface, to the depth of 8 or 10 inches, is covered with a layer of fine loose sand.

(2.) That underneath the sand is found a conglomerate of amorphous porphyry, feldspar, chloride of sodium, magnesia, gypsum, &c., cemented by the sulphate of lime into a hard, compact mass to a depth of 6 to 10 feet, called the "costra," or crust.

(3.) That below this crust the caliche, or impure nitrate, is found, presenting to the view a variety of colours—yellowish-white, orange, bluish-grey, &c.

The nitrate deposit being reached, which, like the crust, is found cemented into a rock-like mass of from 4 to 6 feet deep, is quarried by blasting with a coarse-grained powder, of which as much as 150 lb. are sometimes used at a single blast. Neither dynamite nor nitroglycerine are used, as it would shatter and pulverise the caliche so as to occasion a serious loss.

After being brought to the surface, the caliche is carefully assorted by experts, called "particulares," broken into pieces double the size of an orange, and carted to the refinery establishment, situated on the Pampas or on the sea-coast, or carried to Iquique, Pisagua, Patillos, and Antofagasta, by rail, each of these places having connexion, by narrow-gauge railways, with the nitrate deposits, and which, consequently, are rapidly becoming the chief centres of nitrate production and export. Of course, if water and fuel were obtainable near the deposits, it would be more economical to carry on the process of elaboration there; but as these essentials can be had more conveniently at the sea-coast, it would seem to be cheaper to bring the caliche to the fuel and water. The fuel used is bituminous coal, brought by sea, mostly from the coal-beds of southern Chili; while water is obtained chiefly by condensation, and, for domestic purposes, is brought in boats from Arica and other points on the northern sea-coast. Some attempts have been made to obtain water by sinking surface wells, but, as it never rains in these regions, success, of course, was impossible. No efforts, as far as I know, have been made to obtain artesian water, but the fact that the snow mountains are comparatively near seems to indicate that an abundant supply might be obtained at no great depth.

#### *Capacity of the Deposits.*

Mr. George Smith, who did so much for nitrate development in Tarapacá, estimates that there is a sufficiency of crude nitrate in that province alone to yield 63,000,000 tons of the commercial article; while Mr. Billingham, in his interesting pamphlet entitled "Estudio sobre la geografía de Tarapacá," estimates the total capacity of the nitrate beds at 178,011,104 English tons. The mean of these two widely differing estimates would be 120,505,552 tons, an amount sufficient to supply the world's uses, at the present rate of consumption, for many centuries.

#### *Method of Purification.*

The conversion of impure caliche into commercial nitrate of soda is effected by means of lixiviation, or leaching. For that purpose elaborate and expensive machinery is employed,

a detailed description of which would be out of place in this report. It will suffice to say that the caliche is dissolved in water at a high temperature, in long tanks, from which the solution is carried in pipes to enormous shallow pans, and the water evaporated by artificial heat, the vapour being conveyed to a condenser, and the water thus distilled saved for further use.

#### *Preparation of Iodine.*

It is found that in every 100 kilos. of impure nitrate there are 50 grms. of iodine, and that in the crystallisation of the nitrate the mother-liquor, called, technically, *aqua vieja*, holds it in solution. In order to extract it this mother-liquor is drawn off into a separate tank and charged with sulphite of soda, with (according to Malloché) the following chemical reaction:—

forming the iodide of sodium; and by the subsequent addition of a further quantity of sulphite, precipitating the iodine, which, containing more or less impurities, is refined by sublimation and condensation.

#### *Export of Nitrate and Iodine.*

The importance of the nitrate trade will be seen from the following figures: The export of nitrate of soda from the ports of Taltal, Antofagasta, Iquique, Pisagua, and Topilka, (Iquique furnishing two-thirds of the whole) for the 10 years ending the 31st of December, 1888, was 4,574,440 English tons, valued at 231,411,182 dols., upon which export duties were collected at the rate of 1 dol. per 100 kilos., to the amount of 87,470,622 dols. During the same period the exports of iodine amounted to 1,588,074 kilos., with a total value of 19,333,757 dols., upon which the Government collected in export duties 1,172,576 dols.

The export duties on nitrate for the year 1888, amounted to 17,447,882.12 dols., and it is estimated by the Minister of the Treasury that for the current year (1889) the amount will exceed 19,000,000 dols.

#### *Destination and Uses.*

Of the large export of Chilean nitrate during the year 1888 Germany took 284,000, Holland 33,400, Belgium 84,800, France 156,500, and Great Britain 104,800 tons. The price in the English market varies from 9*l.* 10*s.* to 10*l.* per ton.

The chief use to which it is applied in European countries is as a fertiliser; in Germany and France largely in the cultivation of the sugar-beet. Very considerable quantities, however—as much as 30 per cent. of the whole, perhaps—are consumed in the manufacture of nitric acid, nitro-glycerin, dynamite, gunpowder, &c. In the preparation of the last-named article the soda nitrate is first converted into the nitrate of potash, on account of the latter being less absorbent of atmospheric moisture.

It will be observed that the United States does not figure as an importer of Chilean nitrate, but it might be to the advantage of our agriculturists and manufacturers of explosives to turn their attention to its use.

#### RESOURCES OF PERU.

##### Report by Minister Hicks, of Lima.

#### *Salt Deposits.*

Closely allied to agriculture is the production of salt, and in this industry the natural advantages of Peru are, perhaps, unrivalled in the whole world. On the Pacific coast, 40 or 50 miles north of Callao, is the port of Huacho, where the salt deposits are sufficient to supply half the world. The Government last year sold the exclusive privilege of manufacturing salt at this point for 27,000 dols. Owing to a peculiar formation of the soil, the sea-water on the shore percolates into the earth and is evaporated by the heat of the sun. Salt is thus formed in masses, almost entirely pure, and is cut in the form of blocks resembling ice. This

natural and automatic manufacturing is constantly going on, and the supply is practically unlimited. This crude salt is generally used by the natives, and is shipped in immense quantities to Chili, where it sells for 1.60 dols. per hundred. The table salt, sold in the groceries of Lima, however, is of English manufacture, as there is no refinery for the article in this country.

A similar deposit of salt is found at Sechura, in the north of Peru, where the privilege for manufacturing was sold last year for 30,000 dols. Sechura supplies Ecuador, Colombia, and the northern part of South America.

#### *Sulphur Deposits.*

Immense deposits of sulphur are found at Tumbes in the north and Arequipa in the south. Sulphur is found so nearly pure that samples have analysed at 99.8 per cent. of pure sulphur.

#### *Gypsum Deposits.*

Fields of gypsum exist in the vicinity of Sechura, but its development has not been attempted on a large scale.

#### *Petroleum Deposits.*

Petroleum is found in the north, near Payta. Prescott speaks of the deposits of asphalt, and remains of ancient oil-wells and retorts have been found in that vicinity. An American gentleman has recently purchased a vast tract of land, 12 miles wide and 20 miles long, at Talara, near Payta, covering the site of these ancient oil works and vast deposits of asphalt, which are called by the natives "pitch mines." This gentleman was one of the original operators in the oil regions of Pennsylvania, and he knows well the value of his purchase. He set to work sinking wells, and now has more than half a dozen spouting oil exactly like the famous wells in Pennsylvania. He is erecting a gigantic system of refineries, and in a few years he will have in operation the largest oil-field in the world outside of Pennsylvania.\*

#### *Coal Deposits.*

In the neighbourhood of Chimbote the coal deposits are said to be very large. Both anthracite and bituminous coal exist on the surface and in ridges above the surface, so that it can be mined with but little expense.

#### *Miscellaneous Minerals.*

The mineral wealth of this country is almost fabulous in magnitude, and includes, besides gold, silver, and coal, immense deposits of copper, iron, nickel, platinum, mercury, and many others.

Lack of capital and skilled labour has prevented the development of its agriculture, and a dependence upon foreign importations to the neglect of its own resources has caused several vital industries to remain undeveloped. Its immen-

\* In a subsequent report to the Department (February 11, 1890), Minister Hicks says: "Referring to my No. 76 of January 21, 1890, in regard to the production of petroleum at Talara, near Payta, in northern Peru, I have to say that the refined kerosene manufactured at that point has appeared in large quantities in this city and Callao, and from its cheapness and excellence it seems likely to drive the American article entirely from these markets. A few days since one shipment of 20,000 boxes was reported as arrived at Callao, and the native article is now on sale at many places in that city and Lima. The experiment of burning crude petroleum in place of coal is being tried on the locomotives of the Oroya railroad, and, if it proves successful, it will open a considerable market for the article among the railroads. They now use English coal, and by thus putting into use an article of home production it will give a stimulus to the manufacture as well as curtail the importation of an English staple."

Under date of March 12, Minister Hicks, of Lima, reports further that Mr. Sutherland Hutton, vice-president of the Mining and Supply Company, of Los Angeles, Cal., has been in Peru, and has just completed a contract with Mr. Herbert W. C. Tweddle, owner of the oil-works at Talara, in northern Peru, by which Mr. Tweddle is to ship 1,500,000 gallons of crude oil every month during the life of the contract, which is to continue five years. This is probably but the beginning of this business, and it would indicate a condition of affairs of considerable interest to the oil-producing industry in the United States.

mineral deposits have not been properly appreciated. The attention of its people is now being called to these points, and a noticeable impetus is being given to its various industries.

#### CONDITION OF THE SISAL INDUSTRY IN THE BAHAMAS.

Report by Consul McLain, of Nassau.

One year ago I made a report to the Department upon the culture of sisal hemp in this colony, calling attention to it as a new industry just being introduced, and which promised to bring substantial prosperity to these islands in the near future.

During the year, and especially within the last few months, so many letters have been received at this consulate from various parts of the United States, making inquiries upon the subject, that I am satisfied a statement touching the present condition of the industry would interest many of our people, and I therefore submit the following:

The progress made in the development of sisal culture in the Bahamas during the past 12 months is marvellous. One year ago there was scarcely a dollar of foreign capital, and very little local, invested in this business in the colony, while to-day parties from Great Britain, Canada, and Newfoundland, representing large resources, are interested in sisal, have bought tens of thousands of acres of Government land, and are industriously engaged in clearing and planting the same to the full measure of their ability to procure the material. A local stock company, styled the Bahama Hemp Company, organised and managed by Nassau capitalists exclusively, has also purchased a large tract of land and is developing the same, whilst thousands of acres are being planted in every direction by individual owners of smaller pieces. American capital up to this date, I regret to say, for it is to its own disadvantage, has been conspicuous by its absence. One company, however, styled the Inagua Hemp Company, organised under the laws of the State of New Jersey, with D. D. Sargent, United States consular agent at Inagua, as manager, has lately procured about 1,200 acres at Inagua and has begun operations.

Messrs. Munro & Co., of St. Johns, Newfoundland, have obtained a grant of 18,000 acres of Crown land at Abaco, and are planting the same. Another tract of 20,000 acres has been allotted to a London company on the same island. Mr. Alex. Keith, of Edinburgh, Scotland, has taken 2,000 acres on Andros Island, and is working upon it. But the largest demand has been made lately by two London companies, who are said to be applying for not less than 200,000 acres between them.

Many applications for land have not been reached at all as yet on the files, the Surveyor-General's Department being hard pushed in the matter of surveys and locations, whilst new applications are being constantly received, and have to await their turn for consideration. So much land has been taken up that the Governor, a short time ago, advanced the price of Crown land from 1.25 dols. per acre, the ordinary price, to 4 dols. per acre, withholding also the benefit of the bounty. And lately it has been decided to sell no more large allotments of Crown land at present, the quantity already allotted with a view to cultivation being as great as the condition of labour in the colony will justify. The number of acres of Crown land already disposed of is about 120,000 acres, whilst pending applications on file and not yet reached will amount to at least 200,000 more.

This substantial withdrawal of Crown lands is creating some movement in real estate—as is natural under the circumstances—between private parties, some old properties changing hands at prices double and treble their supposed values two years ago. Persons buying private lands and cultivating them will share in the bounty of 1 per cent. per pound provided by law on all fibre raised and exported. Private lands in New Providence can be bought, unimproved, for from 8 dols. to 12 dols. per acre, and for less on the out-islands.

The employment given to labourers in clearing land and in setting out plants has already put considerable money into circulation, the beneficial effects of which are being felt in various quarters. There has been no special advance in the price of labour, field hands commanding from 40 to

60 cents per day, and finding themselves. Each month, however, witnesses a large increase in the number of those who find remunerative employment, and pleasant relations obtain between employers and employed.

The labour question has been and is one that here, as elsewhere, requires delicate treatment; but it has been skilfully met by Sir Ambrose Shea, the Governor, who long ago perceiving that to permit investors to locate upon adjoining lands would induce sharp competition in wages in thinly settled districts, adopted the plan of scattering the allotments about the different islands, or in localities remote from each other on the same island, so that each settlement should have its share of the benefits of the new industry by obtaining, at fair wages, employment for its local labour. In this way, also, a surplus of labour at one point and a scarcity at some other has been avoided. When the entire labouring population becomes employed, as will happen before long at the present rate of development, a new phase of the labour question will arise; but that time is yet in the future, and the remedy can be applied when the situation demands it.

Small shipments of fibre continue to be made by nearly every steamer, a few old plantings furnishing the material. It is not likely that shipments in any quantity will be possible under two years, but after that time an enormous increase may begin to be looked for, increasing steadily as new fields come into bearing, until the annual exports of the colony, which now average about 600,000 dols., will leap well up into the millions, as a moment's reflection will show. It is a very low estimate to expect half a ton of fibre per acre, and a very low estimate to call it worth 100 dols. per ton, for it is worth over 200 dols. per ton in the world's markets to-day. When even the present quantity of land sold and applied for, to wit, 300,000 acres, is bearing, which ought to happen within five or six years, it will produce 150,000 tons a year, worth 15,000,000 dols.—an increase of prosperity that sounds more like a fairy tale than a strong probability deduced from reasonable figures. And yet 300,000 acres is but a small portion of the uncultivated lands within the limits of the Bahamas.

It is estimated that about 6,000 acres of land have already been planted in sisal (a plantation once started needs no replanting for many years), and that many additional ones have been cleared and made ready for the plants, the obtaining of which has been almost impossible, the industry being seriously retarded thereby. The prices paid for plants have risen from 6 cents per dozen to 36 cents, so great has been the demand; but the price will now decline rapidly, since the supply of plants is developing enormously, about 2,000,000 being now available for planting, and others coming on speedily. The pita plant is being found on all the islands growing wild, and the stock of old plants is very great. From the centre of the old plant rises a pole about 16 ft. in length, on the branches of which small plants grow, averaging a thousand to each pole, and from these poles a vast supply is coming into market, creating a profitable business; for what were two years ago only noxious weeds have all at once become worth 20 dols. apiece for pole plants alone. Quantities of old plants have lately been discovered growing on the cays along the Florida coast, and small schooners are already buying these up and bringing them here for sale. This fact suggests the question whether this new hemp industry, which is about to revolutionise the condition of the Bahamas, may not also be developed in the southern portion of Florida. The plants are found there growing wild just as they are in these islands, and they flourish best in dry sandy soils, fit for little else. I would earnestly call the attention of the Department of Agriculture to this matter, and suggest the propriety of looking into it, and of calling the notice of the people of Florida to this possible source of wealth and prosperity. The conditions of soil, climate, &c. which make its culture a success here, may not obtain there, but the simple fact that the plant is found growing wild in Florida, is of itself a consideration that should warrant an investigation at the hands of the Department.

The unexampled success of the sisal industry in so brief a period in this colony is entirely attributable to the business-like, systematic manner in which it has been

managed by the present Governor, Sir Ambrose Shea, who has all along taken a most earnest interest in the matter. He is a man of large experience in affairs, and has practical knowledge of the proper way to manage industrial enterprises. From the start he realised that this industry would be the salvation of the Bahamas, and, setting his heart upon it, he pushed it forward with great energy and prudence, overcoming numerous difficulties, surmounting obstacles, encouraging the faint-hearted, until now the people are touched with his own enthusiasm, and the industry is fairly afloat. He visited England, and by personal effort enlisted capitalists and procured large investments. To Sir Ambrose Shea the colonists owe a large debt of gratitude, and when the signal prosperity which is already hanging over the islands shall have been developed, to its full measure, they will more perfectly realise how, not only their individual interests, but those of outside investors, have been wisely and prudently promoted and guarded from the very inception of the industry by the practical, discreet, and conservative action of their Governor.

There can be no doubt or question as to the success of sisal culture in this colony. It has passed far beyond the experimental stage, and is giving daily evidence that it will become a source of wealth to all concerned. The combined conditions of soil and climate especially adapted to the growth of first class fibre give this colony a marked advantage over other West Indian islands, where the plant may grow luxuriantly enough, but will be found deficient in good, strong fibre. The poorer and more sterile the soil the better the result, and here the plant flourishes where ordinary vegetation seems almost impossible. It is a plant of unfailling growth; it will live without rain to moisten the soil; you can scarcely exterminate it if you try; it requires but little cultivation, and at an expense below that of almost any other agricultural product; and its value is substantial.

As two-thirds of the trade of the Bahamas is now with the United States; as their only steam communication with the outside world is by a subsidised line of American steamships running between Nassau and New York; as their increased wealth and prosperity means a larger and more profitable commercial intercourse with our own country, we should view this coming development of their material interests with pleasure, and with the warmest wishes for its complete success.

In conclusion, I would add that I have sent by this mail four samples of the Bahama fibre for the information and satisfaction of the State Department, believing that the same would be of sufficient interest to justify me in so doing. These specimens were not specially selected, but are only fair samples of the average fibre which is now being grown and shipped from the colony. Two of them have still attached a stub, or portion of the butt end of the leaf, which was purposely not passed through the machine, showing the character of the sisal plant whence extracted.

#### AMERICAN IMPORTS AT BARRANQUILLA.

Under date of January 7th, 1889, Vice-Consul Whelpley reports that the imports from the United States more than doubled during the year 1889, if landing certificates may be taken in evidence. Probably the most marked increase is on refined sugar, as an article for illustration. During the calendar year 1888 landing certificates were issued for 625 half-barrels refined sugar; the calendar year 1889, by record of landing certificates, shows 40 barrels and 2,824 half-barrels to have been landed; caustic soda, 109 drums, against 70 for the year previous, and other imports in like proportion. The new coffee crop, now in commencement of shipment, bids fair to excel past records.

#### A NEW PROCESS IN GLASS MANUFACTURE.

Report by Consul Monaghan, of Mannheim.

In the manufacture of glass a new and important improvement has been recently reported. It is believed that a complete revolution in the manufacturing methods must take place. Formerly, panes and plates of glass were produced by blowing large hollow cylinders, which were

afterwards cut and pressed. The blowing process, so tiresome and unhealthy to workmen, is to be entirely done away with. The glass manufacturer, Simon, has a new process, by which the tough glass may be run through rolls and made flat, smooth, and of any width and length. The plate-glass so produced is distinguished by greater homogeneity, firmness, toughness, and clearness; besides, the surfaces receive a brilliancy of finish little less beautiful than the finest cut glass. The essential part of the new system consists in the use of peculiarly formed waved hollow metal rolls, which are heated from the inside by means of steam or gas. These rolls take the tough liquid glass direct from the melting pot and run it out into long sheets like those of tin or sheet iron. To avoid sticking of the glass to the rolls the latter are covered with a thin coating of coal-dust, oil, and wax. When one considers the marvellous increase in the demand for sheet and plate glass, and that its former production was at the cost of much money and the health of employes, the present discovery must be regarded as of great importance. It is expected to reduce the cost of production, and consequently the selling price, very materially.

#### THE MANUFACTURE OF PERFUMES AT NICE.

The following is an extract from a report by Her Majesty's Consul at Nice upon the manufacture of perfumes in that district:—

"The art of producing scent is well understood in my district, but can only be acquired by long practice, by which alone the blending of the primary essences in proper proportions becomes thoroughly understood.

"The first process is the extraction of the essences by distillation. A large copper vessel or alembic is filled with water to about two-thirds of its capacity; the flowers to be treated are then introduced, and it is hermetically closed. It is then placed on a fire; usually, in our days, gas or steam is used for this purpose. Steam is generated by this means in the cylinder, and is carried by means of a pipe into a second cylinder, which is constantly kept replenished with cold water, and is furnished with an overflow cock. The pipe, in its passage through this second cylinder, assumes the form of a spiral coil. This coil ends in a cock at the bottom of the cylinder, from which the volatile essence exudes drop by drop as the steam becomes condensed in its passage through the spiral coil. In this manner the essence is collected in a small glass vessel, while at the same time the water containing a small portion of the scent, and which still remains in the alembic aforesaid, is itself perfumed, and becomes the rose water or orange flower water of commerce. All flowers are not susceptible of this treatment—some of them, such as jessamine, violet, cassia, tuberose, &c., containing no essence, have to be treated by a different process, which will be presently described. Of the flowers producing essences the orange flower produces but 1 grm. of essence for 1 kilo. of flowers, or but one-thousandth part. This essence is styled 'neroli,' and is the principal essence produced in the district between the Var and the Italian frontier.

"The following table will show the proportionate yield of the different flowers:—

Neroli .....	1,000 kilos. of flowers	1 kilo. of essence.
Rose .....	25,000 " "	1 " "
Geranium .....	1,000 " "	1 " "
Mint .....	1,000 " "	0.750 " "
Orange leaf (bitter) ..	1,000 " "	1 " "
Lavender .....	100 " "	0.500 " "
Eucalyptus .....	100 " "	0.500 " "

"The volatile essences thus obtained, combined and mixed together with a certain quantity of alcohol, are used in the preparation and as the basis of Eau de Cologne, toilet vinegar, lavender water, &c. There are two processes used for the purpose of extracting perfume from flowers which do not contain the volatile essence. The first may be described as the cold process, and the second as the hot process. The former is generally used for cassia (*Aracia Farneriana*), jessamine, jonquils, tuberoses, violets, and some other flowers.

"Freshly-gathered flowers are placed upon a layer of pure lard, a quarter of an inch in thickness, spread over a sheet of glass about two feet square, which is framed in wood and forms a kind of tray. These trays, sometimes some 40 or 50 together, are then piled upon one another; the flowers are changed every 12, 18, or 24 hours, according to circumstances, and the process is thus continued until the lard is sufficiently charged with perfume. Jessamine and tuberose are frequently changed as often as 50 times before the lard is considered to be sufficiently impregnated, cassie and violets from 30 to 40 times, and jonquils about 20 times only. The fat thus obtained can be packed in air-tight tins and conveyed anywhere.

"When the hot process is resorted to for the purpose of obtaining the impregnated fat, 20 kilos. of grease are placed in a copper vessel, together with some 5 kilos. of flowers; the vessel is then placed over a slow fire, and the contents are well stirred. After allowing the compound to boil for 10 minutes, the vessel is left to cool for some hours; an additional 5 kilos. of flowers are then added, and the process is repeated until the fat has absorbed the requisite amount of perfume; the hot liquid is then poured through a sieve, and the greasy flower-paste that remains is subjected to hydraulic pressure. It is in these two ways that the 'pommades' of trade are produced.

"From these 'pommades' perfumed and alcoholised liquids are extracted by means of grain spirit and also by spirits of wine; these are the 'extraits' of trade, and it is by the judicious blending of the different essences and concentrated perfumes, obtained by the processes above described, that the numerous scents are produced.

"The principal 'parfumeries' of my district are situated at Grasse, but the Bermonds and Lhermines of Nice are well-known houses; the latter of which appears to be at present the most important manufactory in Nice and its neighbourhood."—(No. 164, *Foreign Office Miscellaneous Series*.)

#### TRINIDAD ASPHALTUM.

Under date of November 10th, 1889, the United States Consul for Trinidad reports that the shipments of asphaltum from Trinidad—the greater part to the United States—from January 1st to June 30th, 1889, amounted to 32,460 tons, being a prodigious increase over any previous semi-annual shipments during the history of the colony.

### MISCELLANEOUS TRADE NOTICES.

#### FRENCH MINING INDUSTRY.

The *Economiste Français* for the 3rd May publishes the following information respecting the French mineral industry in 1889, which has been extracted from an official report addressed to the Minister of Public Works by M. Lorieux, *Inspecteur Général*, and M. Keller, *Ingénieur, des Mines* :—

The quantity of coal extracted from French mines in 1888 was not less than 22,603,000 tons, which represents an increase of 1,315,000 tons in the year, and the provisional figures show, for 1889, a further increase, still larger, which approaches two million tons.

In the metal industry the progress is less marked. The production of steel and iron is far from attaining the level reached in 1883, before the crisis. However, the revival in trade which manifested itself in 1887 continued in 1888, and increases have been notified in the manufacture of cast irons and steels in 1889. The forges, properly so called, have suffered for some time from their mutual competition and from that of the steel works. At present, orders for rails are waiting; on the other hand, the sale of bars and of sheets of the same metal share in the growing favour shown to the bars and plates of Bessemer or Martin steel, the price of which is constantly diminishing.

France continues to take from neighbouring countries, from Belgium, England, and Germany, for instance, nearly one-third of the mineral combustible necessary for its consumption. This fact is in itself a sufficient proof that the French collieries stand in need of considerable development. As regards the foreign trade, the state of affairs is

very different for the iron and steel works. They are sufficient for present requirements; several of them have created a market abroad, and export the excess of their production. Everywhere abroad, in England, the United States, Germany, Belgium, and Austria, the extraction of coal has redoubled in activity. More than one million human beings work daily in winning coals from the bowels of the earth. As far as can be judged by the official statistics of the principal civilised countries, the production of mineral combustibles in the whole world increased from 435 million tons in 1887 to 470 million tons in 1888.

For pig iron, the greater part of which forms the basis of the iron and steel industry, the production has increased approximately from 23 million tons to 23½ millions in the same period. The increase has been neither so marked nor so general as for coal. France maintains the fifth rank among the nations, under the double head of the coal industry and of the metal industry.

The number of workmen employed in 1888 in the mines of every kind in France and in Algeria was 116,000; moreover, the working of ores and of quarries has given work to 115,000 persons. Accidents were neither more serious nor more numerous than in the preceding year.

#### HIDE EXPORTS FROM INDIA.

The Calcutta *Englishman* for the 6th May says :—

India furnishes the United Kingdom with more hides and skins than any other country in the world, and during the last three decades the export of hides from Calcutta has trebled. Speaking broadly, the hide trade belongs to Bengal, and the skin trade to Madras, which is due partly to the fact that the total number of horned cattle is greater in the area served by Calcutta than in the area served by the port towns of Southern India, and also to the superior reputation enjoyed by the tanneries of the Madras Presidency in the dressing of skins. Hides and skins for export are gathered from all parts of India as far as the Punjab, and last year the number of hides imported into Calcutta was 120 lakhs.

#### CULTIVATION OF THE SUGAR BEET IN ONTARIO.

The Toronto *Monetary Times* for the 2nd May last has the following :—

An experiment has been in progress in Ontario since May last, undertaken with a view to learn how the sugar beet of Germany and Bohemia can be successfully grown in this country. Beet seed from those countries has been planted in Quebec. Mr Wilfrid Skaife, of Montreal, manager of the Berthier Beet Sugar Company, has been importing the seed, and getting the farmers along the St. Lawrence to cultivate the beet, with only fair success. He has sent for distribution through Ontario a quantity of sugar beet seed, in order to ascertain whether our soil and climate were adapted to produce roots of a quality suitable for the manufacture of sugar. This seed was accordingly distributed, in the hope that Ontario agriculturists would try them on a larger scale and with more pains than the French-Canadians seemed disposed to give. Should they do so, and with good results, Mr Skaife's company might open a branch factory in this province.

A warm interest in the experiment was taken by the Ontario Minister of Agriculture, who ordered a quantity for the model farm at Guelph. Last autumn he got Mr. R. H. Lawder to visit the farmers east of Toronto who sowed the seed and ascertain the results, to procure samples for analysis, and to report to the department. From the House of Assembly reports it is learned that there were drawbacks to the success of these experiments, the principal ones being that, owing to the lateness of the season when seed was sown, generally about May 15, many of the beets had not thoroughly matured at the time in October when the samples were taken; also want of information as to some of the peculiarities of sugar beet cultivation. For instance, close cultivation is necessary to secure rich saccharine quality and the roots need to be kept covered with earth. Our Ontario experimenters, however, set them out far apart, and allowed the roots to grow partly above ground.

The experiment was worth making, however, as proved by the results, which are encouraging. The yield per acre averaged over 20 tons; 80 per cent. of the roots analysed showed a percentage of sugar from 14 up to 17 per cent., but the purity of the sugar leaves room for much improvement, probably for the reasons given above.

The largest plot raised was on the Gulph farm, the yield from which is thought equal to 20 tons per acre, which is a fair yield for good soil in this province. Professor James analysed average beets from this crop, and reports polariscope reading 18 per cent., and the percentage of sugar in beet 17.10, coefficient of purity 83.7. These beets, says the report, were raised in rows 24 in. apart, and thinned out to 7 or 8 in. apart in the rows, and the roots in this case were all kept entirely underground. Such results as these, if they can be attained in various parts of the province, will make certain the success of the beet sugar.

#### INDIAN INDUSTRIAL PRODUCTS.

The following information respecting dyes and tanning materials and lac are extracted from a memorandum on Indian inland trade compiled in the Revenue and Agricultural Department of the Government of India, and which has recently been issued from the Government central printing office at Simla:—

*Dyes and tans* comprise indigo, myrabolams, cutch, turmeric, aniline dyes, and "others"; the first is by far the most important and stands at 323 lakhs of rupees\* in a total trade in dyes and tans valued at 442 lakhs of rupees.

Bengal, the North-Western Provinces and Oudh, and Madras, are the principal sources of commercial indigo, and their combined exports during the year amounted to 289½ lakhs of rupees, viz.: Bengal, 187½ lakhs of rupees; North-Western Provinces and Oudh, 73½ lakhs of rupees; and Madras, 28½ lakhs of rupees. It is also grown rather extensively in the Punjab, but chiefly for local consumption. Elsewhere its cultivation is not unknown, but it is unimportant.

Indigo manufacture in Bengal has a long history marked by many vicissitudes of fortune; but notwithstanding some serious checks, and in later years the competition of faniline and other dyes, it continues to hold its place as one of the great industries of the province. The total area under indigo in Bengal is estimated to be 588,000 acres, and the manufacture is in the hands of European capitalists. The season was fairly prosperous and the exports amounted to 90,616 maunds.

In the North-Western Provinces and Oudh indigo is largely cultivated in the districts to the east of Allahabad, and in the central and western half of the tract lying between the Ganges and Jumna rivers, where canal irrigation has led to a considerable extension of the acreage under this crop. The total area now under indigo in the North-Western Provinces and Oudh averages about 337,000 acres. Unlike Bengal, the manufacture is, except in the eastern districts adjacent to Behar, in the hands of natives. The crop of 1888—89 was not a good one owing to heavy and frequent rainfall, and exports fell from 43,000 maunds in 1887—88 to 40,000 maunds.

Madras indigo is commercially less valuable than that of Northern India; its cultivation is confined to the Northern Circars, but is extending, and the total area is between 400,000 and 500,000 acres. The exports were 23,866 maunds, against 26,000 maunds in the preceding year.

The indigo area in Punjab is returned as 138,000, of which 82,000 are comprised in the districts of Multan, Muzaffargarh, and Dera Ghazi Khan, where the indigo exported from the province is manufactured. The exports go to Sindh and Karachi. During 1888—89 amounted to 14,085 maunds, valued at 12.39 lakhs of rupees.

A noticeable peculiarity of indigo culture is the extent to which the cultivators of Behar depend on the North-Western Provinces and Oudh and the Punjab for seed. The exports of seed from these provinces average 1.5 lakhs of maunds a year.

Myrabolams, the fruit of a species of *Terminalia*, are exported principally from the forests of the Central Provinces and Bombay to Bombay town. During the year the exports of the Central Provinces amounted to 5.31 lakhs of rupees in value, and of the Bombay Presidency to 3.34 lakhs of rupees. With the opening of the railway from Nagpur to Bengal the trade may be expected to increase rapidly.

The Indian trade in cutch is insignificant compared with that of Burma, and the total value was under 8 lakhs of rupees. Of this about 2.5 lakhs of rupees is the value of cutch imported through Calcutta and Madras seaports from Burma. Punjab and Bombay derive their inland supplies from the North-Western Provinces and Oudh.

Turmeric, the roasted root-stock of *Curcuma longa*, is a condiment as well as a dye, and is extensively used by natives and Anglo-Indians for this purpose. The principal localities of production are Bengal, Madras, and the North-Western Provinces and Oudh. 6 lakhs of rupees went to port-towns, 7.5 lakhs of rupees to British provinces, and 2 lakhs of rupees to native States. A larger quantity went to the Punjab (value, 2.34 lakhs of rupees) than to any other province, which is perhaps to be partly accounted for by the fact that yellow is a favourite dye of the Sikh nation.

The growing popularity of aniline dyes is illustrated by the general distribution of the imports by sea among the internal trade blocks. Assam and Sindh are the only provinces which do not appear to import them. The Nizam's territory, Mysore, and Berar take them to a very moderate extent, but these provinces probably get the bulk of their supplies by road.

*Lac*.—Of the three commercial products of the insects (*Coccus lacca*) which causes the secretion of this resin, viz., stick-lac, shell-lac, and lac-dye, the trade in the two former only is separately recorded. Lac-dye, which is obtained from the washing of stick-lac and is a colouring matter derived from the female insect embedded in the resinous secretion, has, since the introduction of chemical dyes, almost disappeared as an article of export. Stick-lac is the crude product encrusting the twigs on which it is formed, but has, it is to be feared, been confounded in the returns in some instances, notably in the case of Assam and Punjab, with the manufactured article. Shell-lac is the pure resin extracted from stick lac, which is pounded and exposed to heat for the purpose. *Coccus lacca* has a wide distribution and affects various trees, but is collected principally from two or three species of fig and *Zizyphus* (ver. Ber) and *Butea frondosa* (ver. Dhak and Palas). The jungles of the Central Provinces, Chota Nagpore, Rewah (one of the Central India States), Mirzapore, and Assam are the chief sources of supply. In Assam the insect is regularly cultivated on two varieties of fig. It is also fairly abundant in parts of the Punjab. The inland trade of the year is valued at 101 lakhs of rupees. Calcutta received 17 lakhs of rupees from Bengal, 32 lakhs of rupees from the North-Western Provinces and Oudh, and 11 lakhs of rupees from Assam. The North-Western Provinces collect the produce of the Central Provinces, Punjab, and Rewah for exportation, and a portion of the consignments from Bengal to Calcutta consists of re-exports of arrivals from Assam.

#### GAMBIER AT SINGAPORE.

Gambier is one of the most important products of Singapore, but although it still maintains its high price, there are many complaints from England that the imported article is heavily adulterated with water. In order to trace the origin of this excess, samples taken from the field, fresh from the boiling-shed, were sent to Mr. Evans, of Bristol, whose analysis, with that as compared with a sample of block-gambier received by him in the ordinary course of trade, was as follows:—Gambier from the field: Tannin, 11.48 per cent.; organic matter, 30.11 per cent.; water, 53.39 per cent.; ash, 4.46 per cent.; less, 0.56 per cent. Trade gambier: Tannin, 14.68 per cent.; organic matter,

\* A lakh of rupees = 1,00,000 rupees.

42.26 per cent.; water, 31.89 per cent.; ash, 6.34 per cent.; loss, 4.48 per cent. This result shows that there is actually less water in the trade article than in the gambier taken directly from the coolies' hands, and negatives the suggestion that the town *towkay* adulterates the gambier after receiving it in Singapore with water to make it heavier. The other suggestion that the gambier has deteriorated of late years from insufficient inspissation, owing to less fuel being used in boiling, seems more probable. In earlier years, when there was no attempt made to protect the forests the destruction of firing was very large, and fuel could be had in large quantities. Now the results of wasteful destruction are being felt, firewood is becoming more expensive and difficult to get, and the gambier is insufficiently boiled and dried. Persons interested in the trade recently conceived the idea of forming a company in Singapore to cultivate gambier on a large scale, but this has fallen through, and there is an idea that this product may be cultivated more profitably—i.e., with European labour—in others of our colonies. Consequently, most botanical establishments have applied to the Singapore Gardens for seeds or young plants, and a large quantity of seed was carefully collected, dried,

and distributed widely, but, as far as has yet been heard, the experiments with it have failed entirely. It seems now certain that gambier seed has a very short duration of life (the Chinese say only 24 hours)—that is, it must be sown as soon as ripe. Thus all attempts to send seed to distant colonies must prove futile. Unfortunately, too, young plants are very bad travellers, and though many have been sent out to different establishments, few appear to survive the voyage. More plants, in as healthy as possible a condition, are now to be sent out to various colonies where gambier is likely to thrive.—*Annual Report of Singapore Botanical Gardens.*

#### RECENT PROGRESS IN SULPHURIC ACID AND ALKALI MANUFACTURE.

##### *Sulphur.*

In spite of the nearly complete abandonment of sulphur for acid-making in Europe, the production of the Sicilian deposits has not declined, as is indicated by the following table:—

PRODUCTION AND DISTRIBUTION OF SICILIAN SULPHUR.

	1883.	1884.	1885.	1886.	1887.	1888.	1889.
	Long Tons.						
Exports to England.....	41,788	40,760	33,402	30,236	31,086	37,455	37,633
Exports to France .....	63,602	65,098	58,264	51,280	56,221	53,927	68,632
Exports to Italy .....	66,810	56,292	49,415	48,658	46,818	48,436	44,317
Exports to America .....	96,629	94,929	90,378	98,590	88,593	128,953	111,838
Exports to all other countries.....	67,563	56,829	74,123	97,691	89,728	86,590	99,592
Total .....	336,392	313,908	314,582	329,455	312,446	355,361	362,012

The United States has for many years imported more sulphur than any other country; the above table shows that more than one-third of the Sicilian product came to America in 1888. In addition to this, constantly increasing quantities of sulphur are imported into the United States from Japan, amounting in 1888 to 6,332 tons. Practically no sulphur was mined in the United States in 1888, the deposits at Cove Creek, Utah, not having been worked, although they produced 3,000 tons in 1887.

Considerable quantities of sulphur, recovered from tank waste in England by the Chance process, have been sent to the United States during the past year, the importations for 1889 amounting to about 1,000 tons. The writer is informed by Mr. George Linder, of Boston, the American agent for the Chance Company, that contracts have been made for 500 tons per month during the present year. The Chance sulphur is nearly chemically pure, and commands a higher price than the Sicilian crude; its chief use thus far is in making sulphur dioxide for the sulphite process of wood pulp manufacture. It would seem particularly well suited for gunpowder making, but has not yet been adopted for this purpose.

The refining of sulphur is still chiefly carried on at Marseilles, where there are now six refineries in operation. These works, with five others at various points in the south of France, produce annually about 60,000 tons of refined sulphur, a very large part of which is used to combat diseases of the vine.

##### *Pyrites.*

The Spanish and Portuguese mines are producing pyrites in undiminished quantities. More than 2,000,000 tons were mined in 1887. The importation of pyrites into England shows no falling off, in spite of the precarious condition of the Leblanc soda process. According to the Board of Trade returns, the quantity of pyrites imported into the United Kingdom during the past six years is as follows:—

##### *Importation of Pyrites into the United Kingdom.*

	Long Tons.
1884 .....	563,073
1885 .....	654,521
1886 .....	556,988
1887 .....	597,595
1888 .....	617,232
1889 .....	643,879

This is practically all supplied by three great companies, the Tharsis and Rio Tinto, in Spain, and Mason and Barry, Portugal. The Rio Tinto Company made efforts some years ago to introduce Spanish pyrites into France and other countries, and to this end established a large plant for the manufacture of Leblanc soda and treatment of pyrites cinders for silver, gold, and copper at Marseilles. These works are still in operation, but owing to the unpromising outlook of the Leblanc process, the project of erecting similar works in Belgium, Austria, and America has been abandoned. French pyrites, containing no copper, mined at various points along the course of the Rhône, is employed at all the chief alkali works in France.

In America the production of pyrites has increased considerably within a few years. In 1888, 54,331 tons of pyrites were mined in the Eastern States, chiefly at the Davis mines, Franklin County, Mass. Large quantities of ore are also imported from Canada and Spain. According to W. H. Adams (*Manufacturers' Record*, February 1890), the mines of Virginia will produce during the present year fully 70,000 tons of pyrites. The same writer estimates the consumption of pyrites for the present year at 250,000 tons. The importations from Canada will probably reach 50,000 tons.

##### *Treatment of Pyrites Residue.*

The treatment of the cinders from burnt Spanish pyrites by the Henderson process is carried on in England on an enormous scale, and is constantly increasing. In 1888

420,415 tons of burnt ore were treated in Great Britain, producing 15,135 tons of copper, 337,500 ounces of silver, and 1,918 ounces of gold.

#### *Present Condition of the Alkali Industry.*

In spite of the strikingly rapid growth of the ammonia-soda industry, there has been no decline as yet in the production of alkali in Great Britain by the Leblanc process. This is shown by the statistics of the importation of pyrites, and by the following table compiled from the latest alkali inspectors' reports.

#### *Salt decomposed by both Processes in the United Kingdom.*

	1884.	1885.	1886.	1887.	1888.
	Tons.				
Leblanc process.....	578,874	598,096	584,323	577,381	590,312
Ammonia-soda process.	89,759	115,032	137,220	158,656	212,181
Total .....	668,633	713,128	721,543	736,047	802,493

These figures show that in Great Britain the older process is holding its own, though the world's growing demand for alkali is supplied by the increase of the new industry. Weldon showed five years ago that soda ash can be produced fully one-third cheaper by the ammonia-soda makers; the survival of the Leblanc process is, therefore, due to the enormous demand for bleaching powder (which has not yet been made economically by any other method), and to the profits gained in the treatment of pyrites cinders. Another important gain to the Leblanc industry is the success of the Chance process of sulphur recovery, which has now been introduced into most of the leading alkali works of Great Britain and the Continent. The effect of this new source of profit will be shown in the returns for the present year. The Leblanc alkali makers have lately devoted themselves almost entirely to the manufacture of caustic soda and soda crystals, for which the older process possesses important advantages over the new.

Outside of England the advance of the ammonia-soda process has been even greater, while the production of the Leblanc works has fallen off in a marked degree. According to the Paris Exhibition circular of the Solvay Company, the world's total production of alkali in 1888, calculated as soda ash, may be estimated at about 900,000 tons. Of this amount 430,000 tons, or about one-half, was made by the ammonia-soda process at the various Solvay works. The latter have increased their production still further during the past year, so that it may probably be safely said that more alkali is to-day produced by the ammonia process than by that of Leblanc.

There are now ten Solvay works in operation, the location and output of which are as follows:—

	Tons.
Belgium (Couillet).....	17,000
France (Varangeville-Dombasle).....	100,000
England (Brunner, Mond and Co., Northwich).....	125,000
Germany (Wylhen, Bernburg, and Saralbe)....	100,000
Russia (Beresniki and Lissitchevsk).....	17,000
United States (Syracuse, N.Y.).....	60,000
Austria (Ebensee, Salzkammergut).....	11,000
	<u>430,000</u>

The works at Geddes, near Syracuse, now supply about one-third of the American demand; in addition to the product of these works there was imported from England in 1888, 125,135 tons of alkali.

Other modifications of the ammonia-soda process, such as that of Parnell and Simpson, and the Schloesing process, introduced by Bell Bros., Middlesbrough, England, are worked only on an experimental scale, and do not yet play an important part in the alkali industry.

#### *The Hargreaves Process.*

The direct conversion of salt into sulphate of soda by the action of sulphur dioxide and steam has come into increased use during the past few years. There are now five works in England using this process, and also one in Ireland and two in France. During the year 1888 these works produced 43,080 tons of sulphate. The advantages of this method over the ordinary salt-cake process are the avoidance of the cost of making sulphuric acid, and the purity and freedom from iron of the sulphate so obtained. No fuel is found necessary, the heat of the reaction being sufficient after the operation is once started. The disadvantage of the method is the high first cost of the plant. Nearly all the plate glass now produced in Lancashire is made from Hargreaves sulphate.

#### *Chlorine and Bleaching Powder.*

The Weldon-Pechiney process, based upon the decomposition of moist magnesium oxychloride by heat into magnesia, hydrochloric acid, and free chlorine, is in successful operation at Salindres, France, and has been introduced on a large scale at the works of Albright and Wilson, at Oldbury, near Birmingham, England. This method accomplishes the final conversion into free chlorine of more than 90 per cent. of the hydrochloric acid employed, while the Weldon process, now universally employed, yields only one-third of the chlorine in a free state. An interesting application of the new process has been made at Szezakowa, Galicia, in the manufacture of chlorine from the waste products of the ammonia-soda industry. The residual calcium chloride is converted into magnesium chloride by treatment with magnesia and carbon dioxide—

(as in the last stage of the old Schaffner and Helbig method of sulphur recovery). The magnesium chloride is treated by the Weldon-Pechiney process for the production of chlorine, and the residual magnesia used over again. This method is a partial solution, at least, of the great problem of the production of chlorine from salt in connexion with the Solvay process. The great obstacle to the employment of the Weldon-Pechiney process on a large scale is, however, the dilute condition of the chlorine liberated, which makes it unfit for the manufacture of bleaching powder. At present the method is employed solely for the production of chlorates, for which it is especially adapted. Until the problem of the manufacture of bleaching powder from this weak chlorine is successfully worked out, it is not to be expected that the process will have an important influence on the alkali industry.

Other methods for the production of chlorine from the ammonia-soda residues appear to be unpromising. The Solvays are making hydrochloric acid on a small scale, at the Varangeville works, by heating calcium chloride with silica, but the plan makes no progress and is probably very uneconomical. Mond's method of obtaining ammonia and chlorine by passing ammonium chloride vapour over heated nickel or cobalt oxide is still wholly in the experimental stage, though the inventor promises full success in two years at farthest.

#### *Recovery of Sulphur from Tank Waste.*

The Chance process has been introduced at 20 works in Great Britain, one in Austria, and one in France. It was recently stated by the manager of the St. Gobain Company, France, that the sulphur so regained is sold at a price equal to three times its cost in the form of pyrites. Considerable quantities of the Chance sulphur are already being exported to America. An important advantage of the process to English alkali makers consists in its availability for the production of either sulphur or sulphuric acid. If pyrites is cheap, sulphur is manufactured and exported to America and other countries; if pyrites is expensive, the hydrogen sulphide produced from the tank waste is simply burned to sulphur dioxide and used over again for making acid. It is interesting to reflect that the sulphur imported into England

becomes a source of nuisance in the shape of tank-waste, but passes through the various stages of sulphur dioxide, acid, sulphate of soda, tank-waste and hydrogen sulphide, and finally appears at the end of the process as beautiful crystalline sulphur, a product of high commercial value.—*Am. Chem. Jour.*

#### MINERAL EXPORTS OF NEW SOUTH WALES.

The following comparative table, showing the mineral exports from New South Wales during the years 1888 and 1889, is compiled from information given in detail in the statistical register of the colony, the first part of which, for 1889, comprising the figures relating to trade and commerce, has lately been issued. From this it will be seen that there

has been an increase in the value of this class of exports of nearly a million sterling. The Broken Hill silver mines have, of course, the lion's share in bringing about this gratifying result, but they by no means stand alone. The value of silver, silver-lead, and silver ore, exported in 1889, exceeds the figures for 1888 by 828,793*l.*, an increase of about 80 per cent. Next in importance stands coal, with an increase of 214,799*l.*, or 20 per cent. The other lines which show increased exportation in 1889 are antimony and antimony ore, bismuth and its ore, copper ore, gold, both in bars and dust and in coin, kerosene shale, and lead. In the other items which go to make up the list, there was more or less of falling off in the value of the export, caused in some instances chiefly by fall in the market price of the metal:

#### EXPORT OF MINERAL PRODUCTS FROM NEW SOUTH WALES.

	1889.		1888.	
	Quantity.	Value.	Quantity.	Value.
Antimony (auriferous).....	1,516 cwt.	£ 1,094	384 cwt.	£ 553
Antimony ore.....	3,112 cwt.	2,250	3,423 cwt.	2,385
Bismuth.....	206 cwt.	7,060	22½ cwt.	410
Bismuth ore.....	644 cwt.	5,734	349½ cwt.	3,501
Bricks (including fire-bricks).....	266,890 No.	642	232,650 No.	942
Coal.....	2,387,702 tons	1,279,271	1,923,872 tons	1,064,472
Coke.....	9,522 tons	15,043	15,249 tons	24,331
Copper (refined).....	81,296 cwt.	207,000	75,721 cwt.	272,110
Copper (regulus).....	901 cwt.	1,166	1,176 cwt.	2,345
Copper ore.....	3,063 cwt.	2,156	1,090 cwt.	579
Fireclay.....	210 cwt.	37	280 cwt.	37
Gold (bars and dust).....	10,966 oz. 2 dwt.	44,649	6,896 oz. 4 dwt.	28,023
Gold quartz.....	2,163 pkgs.	2,038	6,523 pkgs.	8,426
Gold coin.....	.. ..	277,082	.. ..	138,317
Iron oxide.....	9,781 cwt.	1,329	15,286 cwt.	2,067
Kerosene shale.....	21,386 tons.	59,835	18,331 tons	52,634
Lead (pig).....	10,146 cwt.	6,721	3,575 cwt.	1,941
Manganese ore.....	.. ..	.. ..	460 cwt.	75
Minerals not specified.....	1,917 cwt.	719	2,386 cwt.	3,438
Pyrites.....	171 cwt.	141	64 cwt.	18
Silver (ingots).....	416,895 oz. 7 dwt.	72,001	375,063 oz. 14 dwt.	66,668
Silver-lead.....	691,836 cwt.	1,565,290	362,045 cwt.	911,117
Silver ore.....	839,309 cwt.	333,507	234,787 cwt.	164,620
Tin (ingots).....	88,173 cwt.	403,182	91,242 cwt.	569,182
Tin ore.....	4,687 cwt.	11,805	4,948 cwt.	13,314
Total value.....	.. ..	4,301,061	.. ..	3,343,155

The increase in export values during the past year, 957,906*l.*, is equal to nearly 29 per cent. It is more than two-fifths of the total increase in the exports from the colony which 1889 shows as compared with the previous year. The statistical returns of production are not yet issued, and it is from them and not from export figures that the condition of gold mining during the year is to be judged. The export of gold is not regulated by the output but by the state of exchanges. In regard to other metals the export returns are the best index we have as to the condition of the mining industry. Taken as a whole they are decidedly encouraging. So much attention has been given to silver mining of late, and so much capital directed

towards it, that it would not have been surprising had the production of other metals suffered in consequence. No doubt this has been the case to a certain extent, but happily not sufficiently to prevent the former export from being maintained, and in some cases exceeded. It should be mentioned that the figures given above for gold coin exported have been arrived at by deducting from the total exports the value of coin imported, and that of the bars and gold-dust sent from other colonies to be minted in Sydney. The actual amount of gold coin exported from the colony during 1889 was 3,157,965*l.*—*Engineering and Mining Journal.*

## UNITED STATES CLASSIFICATION OF PHOSPHATE LANDS.

The registrar and receiver of Gainesville, Fla., in a letter of 15th October 1889, asked the Department in Washington if lands containing phosphate came within the law relating to mineral lands. The Department replied on December 11th, 1889, that non-metallic mineral substances generally are classed as mineral; but, in the absence of any specific ruling as to phosphate, and because of regard due to the bona fide claimants under the homestead and pre-emption laws where the patents had not issued, Commissioner Groff directed a full report to be sent him, and meanwhile the receipt of mining applications for phosphate claims to be suspended. The registrar reported, December 20th, 1889, that the phosphate found in Marion and Citrus counties is of the highest quality, that the lands which must be surveyed in order to ascertain the quantity are more valuable for these deposits than for other purposes, and that the phosphate can be marketed at a fair profit. In reply to this report the commissioner rules, April 15th, 1890, that phosphate, included in "all valuable mineral deposits" in section 2319, Rev. Stat., "is subject to disposal under the mining laws as mineral land."—*Engineering and Mining Journal*.

## THE PROPOSED CHEMICAL UNION.

Negotiations have been going on for the formation of the Leblanc alkali manufacturers of the United Kingdom into a chemical union or syndicate on the same lines as the Salt Union. Valuations of works have been made, and the amount of capital has been fixed at something like 6,000,000*l*. It is said that the majority of the manufacturers are in favour of the scheme, but there are about five or six makers who up to the present decline to join the combination. The promoters of the scheme perceive that it would be dangerous if such a number of independent firms continued to work outside the Union; but they are still sanguine of gaining some, if not all, of the dissenting manufacturers into their fold. The Union would control the sales of all the chemicals made at the combined works, and hopes, in this manner, to circumvent the ruinous competition which has been going on for many years amongst the various manufacturers. The articles which it would be most easy for the Union to manipulate are bleaching powder and caustic soda, the former being entirely produced by the Leblanc process, and the latter, although it is possible to make it by the ammonium process, cannot be turned out in practice under that system on account of the higher cost of manufacture as compared with the former process. For soda crystals and soda ash the ammonia soda makers have the sole control of the market, and it is only to use up the sulphite of soda produced in the manufacture of bleaching-powder that Leblanc manufacturers produce these articles, as there is a heavy loss on them, which they must look to bleaching-powder to make good. The quantity of bleaching-powder produced in the United Kingdom in round numbers is about 150,000 tons, and of caustic soda 180,000 tons per annum, so that if the "Chemical Union" be successful, and these articles of manufacture would have to provide the dividends, consumers might expect to have to pay considerably more than they do at present for bleach and caustic. It is also possible that, as many of the Leblanc manufacturers are financially interested in the ammonia-soda companies, some arrangement might mutually be agreed upon to raise the price of soda products so that all round consumers would have to pay more for their chemicals.—*Chemist and Druggist*.

## THE DISTILLING INDUSTRY IN GERMANY.

Official statistics show a production of pure alcohol in the half year, ending April 30th last, amounting to 2,479,161 hectolitres. The exports of raw and refined spirits for the first quarter of 1890 amounted to 204,724 cwt. as against 40,266 cwt. in the corresponding period of 1889.—*Industries*.

## NEW QUICKSILVER MINES.

An important discovery of cinnabar has been made at Kurusz, in the district of Dagestan, in Poland. The ore assays 74·7 per cent. of mercury. Preparations are being made to work those deposits at once.—*Ibid*.

## EXHIBITION AT BARCELONA.

An exhibition of appliances for sprinkling vines with chemicals is to be held in Barcelona this year.—*Ibid*.

## DISCOVERY OF SALT BEDS.

Two important discoveries of salt deposits have been made. The borings which have been going on at Barrow-in-Furness on Walney Island have resulted in the discovery of an extensive bed of salt. Sinking operations, which have been carried on near Winsford, in Cheshire, have also resulted in the discovery of brine at a depth of 74 yards. The brine is equal to that generally found in the Cheshire district.—*Ibid*.

## FORMATION OF ALKALINE SULPHIDES.

M. Berthelot, in a communication to the Academy of Sciences on the reduction of alkaline sulphates by hydrogen and carbon, states that the first effect of hydrogen upon the sulphate—*e.g.*, potash—is to form potassium hydrosulphide and potassium hydroxide. The former in the next stage decomposes into potassium sulphide and sulphuretted hydrogen, and the latter combines with the caustic potash to form again potassium hydrosulphide and water. Another reaction takes place between the alkaline sulphide and water vapour, viz.:— $K_2S + H_2O = KHS + KHO$ . The reduction by hydrogen takes place at a comparatively low temperature. M. Berthelot also shows that solid carbon, even at a very bright temperature, fails to react with the sulphate, but that carbonic oxide at a bright red heat reduces the salt according to the equation—

## CHEMICAL MANUFACTURERS AND THE GERMAN LABOUR LAWS.

The chemical industries of the provinces of Rhenish-Prussia and Westphalia have decided to petition the German Reichstag, through their organisations, against the proposed law on Sunday rest and the liability of employers for accidents to their hands and the sanitary condition of the works. The petition points out that the Bill particularises over 280 different branches of chemical industry as coming under its provisions. Among these are a large number of processes in which it is absolutely necessary to continue working on Sundays and holidays. In some instances uninterrupted labour is required to produce the object of the manufacture, in others the machinery cannot be stopped without serious loss, especially in processes where a high or equal temperature is a necessity. With regard to the length of working hours, it is also pointed out that the course and duration of many chemical processes which require constant supervision cannot be estimated beforehand.—*Ibid*.

## CHEMICALS AND LONDON SEWAGE.

In view of the warm weather the London Council are taking the usual steps for applying chemicals to the sewage in various parts of London, and at outfalls upon the Thames. The expenditure for manganate alone is reported to amount to over 20,000*l*. a year. The condition of the river has decidedly improved between Gravesend and Greenwich, owing to the carrying out to sea of the wet sewage mud, of which it is reported that nearly 250,000 tons has been discharged in the Channel. Meanwhile Sir Benjamin Baker is engaged on the report he has to make upon the whole question of the London sewage system and its disposal.—*Ibid*.

## LANCASHIRE ALKALI WORKS AND THE PRODUCTION OF SULPHUR.

In the House of Commons, on the 22nd ult., Sir Lyon Playfair said: I beg to ask the President of the Local Government Board whether, in view of the recent establishment in Lancashire and elsewhere of an important manufacturing process for the extraction of sulphur from the tank-waste of alkali works, steps will be taken to include this and similar operations involving the production of noxious gases under the provisions of the Alkali Act. Mr. Ritchie: This matter has been receiving my attention, and I have given directions for the preparation of a Bill on the subject.—*Chem. Trade Journal*.

## A NEW RED GLASS.

A new red glass has been recently produced in Germany. Besides its use for the manufacture of bottles, goblets, and vases of various kinds, it will be found applicable in photography and in chemists' and opticians' laboratories. This glass is produced by melting in an open crucible the following ingredients: Fine sand, 2,000 parts; red oxide of lead (minium), 400; carbonate of potash, 600; lime, 100; phosphate of lime, 20; cream of tartar, 20; borax, 20; red oxide of copper—protoxide—9; and binoxide of tin, 13 parts. By a single melting a transparent red glass is said to be obtained of very fine quality, of which various objects can be manufactured directly without the necessity of a second heating to intensify the colour.—*Ibid*.

## THE IRON AND STEEL INDUSTRIES OF THE UNITED STATES.

If anything more were needed to illustrate the material progress made in recent years by the great Republic on the other side of the Atlantic, it is amply provided for by the report—always of considerable interest, but more than usually attractive on the present occasion—on the American iron trade in 1889, which has just been presented by Mr. James M. Swank to the American Iron and Steel Association, the headquarters of which are at Philadelphia. Beginning with pig iron, concerning which reliable data are available, thanks to the efforts of the American Iron and Steel Association and the British Iron Trade Association, we find that the output of crude iron during the last few years in the two countries was as follows:—

Years.	Great Britain.	United States.
	Tons.	Tons.
1882	8,586,980	4,623,323
1883	8,529,300	4,595,510
1884	7,811,727	4,097,868
1885	7,415,469	4,044,526
1886	7,000,754	5,683,329
1887	7,550,318	6,417,148
1888	7,998,909	6,482,738
1889	8,245,336	7,693,842

It will be seen that the British *maximum* production was attained in the year which begins the above table, while the United States are increasing their production of pig iron so steadily that they are evidently destined to become, at an early date, the leading pig-iron-producing country in the world, possibly attaining this distinction in 1890. That the United States are using proportionately more pig iron than Great Britain is shown by the fact that the consumption of crude iron in this country rose from 7,052,291 tons in 1888

to 7,692,230 tons in 1889, while in the United States it jumped from 5,864,950 tons to 6,962,800 tons.

If we turn to the production of steel in the United States and Great Britain, the comparison is even more striking. We subjoin a table showing the production of Bessemer steel ingots (including Clapp-Griffiths steel ingots) and steel rails in Great Britain in the last 13 years, compared with the production of the United States in the same period. For the sake of strict accuracy, it should be observed that in the ingot tonnage for the United States for 1889 is also included the small quantity of Robert-Bessemer steel made in that year.

Years.	Great Britain.		United States.	
	Ingots.	Rails.	Ingots.	Rails.
	Tons.	Tons.	Tons.	Tons.
1877	750,000	508,400	500,524	385,865
1878	807,527	622,390	653,773	491,427
1879	834,511	520,231	829,439	610,682
1880	1,044,382	732,910	1,074,262	852,196
1881	1,441,719	1,023,740	1,374,247	1,187,770
1882	1,673,649	1,235,785	1,511,687	1,284,067
1883	1,553,380	1,097,174	1,477,345	1,148,709
1884	1,299,676	784,068	1,375,581	996,983
1885	1,304,127	706,583	1,519,430	959,471
1886	1,570,520	730,343	2,269,190	1,574,793
1887	2,689,403	1,021,847	2,936,083	2,101,904
1888	2,032,794	979,083	2,511,161	1,886,277
1889	2,140,793	943,048	2,930,204	1,510,057

The race between the two largest steel producers of the world has been keen, but the United States have now for some years eclipsed this country in the output of Bessemer steel ingots and rails. In the production of ingots, the race was won by America only in 1884, while with regard to Bessemer rails, the supremacy of the United States was asserted in 1879. Since that year, the construction of railways proceeded at a tremendous pace in the States, the mileage built reaching a total of 11,569 miles in 1882, after which, the rate of building fell off somewhat; but the total rose to 12,872 miles of new track in 1887, the largest annual record ever made by any country.

If we consider all kinds of steel made by the two great steel-making countries, the United States were ahead of their European rival in 1886 and 1887. In 1888 and 1889, however, Great Britain again asserted her supremacy. She now excels as a steel producer, because of her large annual output of open-hearth steel, which is extensively used in ship-building in this country, a field in which the United States is idle, owing to its protective tariff having killed its mercantile marine.

The figures for the last six years' production of open-hearth steel are:—

Years.	Great Britain.	United States.
	Tons.	Tons.
1884	475,250	117,515
1885	583,918	133,876
1886	694,150	218,973
1887	981,104	322,069
1888	1,292,742	314,318
1889	1,429,160	374,543

The production of steel ignots of all kinds in the two countries in 1889 may be summarised as follows:—

Description.	Great Britain.	United States.
	Tons.	Tons.
Bessemer steel.....	2,140,793	2,930,204
Open-hearth steel.....	1,421,039	370,543
Crucible steel (about) .....	100,000	75,865
Other steel .....	Nominal	5,120
Totals .....	3,661,832	3,385,732

The English statistics of finished iron do not cover the same ground as those published by the American Iron and Steel Association, and therefore it is difficult to make comparisons. The output of puddled bars in Great Britain was as high as 2,841,534 gross tons (of 2,240 lb.) in 1882; it fell to 1,616,701 tons in 1886, rising again to 1,701,312 tons in 1887, 2,031,473 tons in 1888, and 2,253,756 tons in 1889. The production of rolled iron of all descriptions in the United States in 1882 was 2,493,831 net tons (of 2,000 lb.); 1883, 2,348,874 tons; 1884, 1,957,307 tons; 1885, 1,804,526 tons; 1886, 2,283,622 tons; 1887, 2,588,500 tons; 1888, 2,411,654 tons; 1889, 2,586,385 tons. In gross tons the quantities were 2,153,263 in 1888, and 2,309,272 tons in 1889.

Reference was made above to the large use of open-hearth steel in this country for ship-building purposes. When it is considered that the shipyards of the United States constructed but 34,354 tons of new shipping in 1887, 36,719 tons in 1888, and 53,513 tons in 1889, while the totals for Great Britain in those years were 577,327, 904,329, and 1,288,251 tons respectively, the insignificance of the American ship-building industry is obvious. The backward state of the United States with regard to the manufacture of tin plates, which is still in its experimental stage in that country, will probably not continue if the provisions of the Tariff Bill now before Congress are retained when the Bill is finally passed. It is surprising that no efforts have been made to "domesticate" such an important industry in the United States, as the use of tin plates is larger there than in any other country, and that the imports, from this country chiefly, are enormous. The British imports of tin plates into the United States have steadily grown from 82,969 tons in 1871 to 331,311 tons in 1889; the total quantity of imports in those 19 years being 3,293,404 tons, and their total foreign value 283,671,246 dols. (56,724,249*l.*) irrespective of the freights and duties paid by the importers. Possibly the increase in the tin plate imports may still continue, for the requirements of provision "canners" and petroleum "packers" are still growing, and they do not look with favour on the increase of duty now proposed.—*Chem. Trade Journal.*

### THE LAW OF PATENTS: SUGGESTED AMENDMENTS.

The Chemical and Allied Trades Section of the Manchester Chamber of Commerce has for some time had under consideration the bearing and application of the Patents, Designs, and Trade Marks Acts of 1883—88.

The Committee of the Section has arrived at the conclusion that certain provisions of the Patent Act of 1883 are mischievous and even impracticable when applied to chemical patents. The Committee is also of the unanimous opinion that some provision ought to be made in the law for distinguishing between mechanical and chemical patents, for the reason that however applicable the existing statutes may be to the former, it frequently happens that its provisions are absolutely impracticable when they come to be applied to the latter.

This fact has already been fully recognised in the German Patent Law by the enactment of special clauses and provisions for the administration of the law in the case of chemical patents. The Committee is further of opinion that if the principle were adopted of distinguishing between mechanical and chemical patents, the probability of litigation in the case of chemical patents would be considerably decreased, and greater justice would be done to litigants.

For the present the attention of the Committee has been directed to the anomalies which result from the operation of section 18, leaving for future deliberation other sections and provisions of the Patent Acts of 1883 to 1888. This section gives power to a patentee from time to time to disclaim, correct, or explain his specification. There is practically no safeguard for the public against the far-reaching power thus granted. It is true that the second clause of this section gives any person the right to oppose an application for leave to amend, and also that the eighth clause apparently limits the rights granted to the applicant by clause 1; but, in fact, both these protective clauses are altogether ineffectual to prevent unscrupulous patentees from evading both the letter and spirit of the law.

According to the existing law a patentee invalidates his patent—amongst other reasons:—

1. If he describes in his specification a process that does not produce the result claimed.
2. If he specifies one or more alternative processes for obtaining similar or equivalent results, and one of those processes does not produce the result claimed.
3. If, in his specification, he uses ambiguous, misleading, or evasive language.
4. If his description is insufficient to enable those skilled in the art to carry out the invention without other aid than that afforded by the specification.

The Committee holds that these just and equitable principles have been made absolutely inoperative by the application and effect of section 18, and that a patentee may now commit breaches of the four principles first set forth, and may abuse a monopoly and privilege which, in their opinion, is already far too easily granted to him, without running the slightest risk of vitiating his patent, because he can confidently trust to his benevolent friend, section 18, to supply him with all the protection of which he may stand in need, and to obtain for him condemnation of his former abuse of privilege, and thus enable him to make good a patent, to the possession of which he was never entitled.

A patentee may now specify and claim almost anything that his speculative and imaginative mind may suggest, without ever having made a single experiment to ascertain the possibility of the realisation of his dreams, so long as he is clever enough to make his original specification sufficiently wide and comprehensive, and to formulate it in such a manner as to permit him, in accordance with section 18, from time to time, to disclaim, correct or explain, without in any way enlarging his claims, or, after such amendment, making the invention substantially different from or larger than the original specification. Favoured by section 18, the speculative faculties of some patentees have of late years been so marvellously extended, that it now frequently happens that a patentee specifies, and claims as part of his invention, chemical products or substances which he has never even seen, much less made or produced.

It may, therefore, well be asked what are the consequences of such an anomalous state of things, in which we have, on the one hand, well-established law and practice, tending to prevent the abuse of a privilege, and on the other, laws to make their operation ineffective.

Great facilities are afforded by section 18 to unscrupulous patentees for evading the law, and the Committee trust they have succeeded in establishing the conviction that this section in its present form operates hurtfully and injuriously on our trades and industries. They now submit their propositions for preventing this abuse of privilege, without doing any injustice or restricting in any way the rights of honest inventors. These proposals are:—

1. To add to Part II., section 5, sub-section 4, of the Act of 1883, the following provisions, which shall be known as sub-section 4b:—"When generic terms are used in chemical

patents, the patentee shall specify *by name or otherwise* each substance or compound which he intends to include within such term or terms, and he shall only be entitled to claim as his invention those substances or compounds which have been so specified by him."

2. Sub-section 4c:—"There shall be deposited at the Patent Office, along with the complete specification of chemical patents, duplicate samples sufficient for analysis or examination of the result or results claimed, and of all raw and intermediate products used in obtaining such result or results, unless such raw or intermediate products shall be ordinary articles of commerce easily obtainable in this country."

3. Sub-section 4d:—"The complete specifications of all patents relating to coal-tar colours, in addition to the samples of the colouring matters themselves, and the intermediate substances used in obtaining them, shall be accompanied by dyed specimens of cotton-wool or silk, showing the results obtained with 1 per cent. and 2 per cent. respectively of the dyes claimed. A complete statement of the method employed in dyeing in each case shall also be given."

The Committee are further of opinion that the words in clause 1, section 18, "from time to time," shall be altered, in the case of chemical patents, into "two years from date of application."

The Committee recommends that a copy of this report be sent to all members of Parliament representing the Manchester district, with the request that they will take the first opportunity of bringing the questions of chemical patents and the working of section 18 before the House of Commons, and that the co-operation of other Chambers of Commerce be invited, especially of all those which are established in chemical centres, such as London, Liverpool, Glasgow, Newcastle, &c.

## BOARD OF TRADE RETURNS.

### SUMMARY OF IMPORTS.

	Month ended 31st May	
	1889.	1890.
	£	£
Metals.....	1,691,075	1,888,375
Chemicals and dyestuffs.....	810,562	649,493
Oils.....	438,509	460,957

## THE TYNE CHEMICAL TRADE.

The exports of chemicals from the Tyne for the past month show a heavy falling off as compared with the corresponding month of last year. Caustic soda has not hitherto been recorded separately, being formally included under the heading of "other chemicals" :—

	May 1889.	May 1890.
	Tons.	Tons.
Alkali and soda ash .....	1,349	1,572
Bicarbonate of soda .....	10	8
Bleaching-powder.....	2,141	2,317
Manure.....	67	622
Soda crystals .....	2,593	1,511
Sulphate of soda .....	7	53
Caustic soda .....	..	1,240
Other chemicals .....	3,766	1,183
Total tons .....	9,963	8,516

—*Chemist and Druggist.*OUR EXPORTS OF DRUGS DURING THE LAST FIVE YEARS.  
(The figures are given in thousands of pounds) :—

Exports in 1,000l. to	1885.	1886.	1887.	1888.	1889.
Germany (with Holland and Belgium).....	979	1,005	980	976	1,036
France .....	354	407	510	551	627
Russia.....	92	79	85	86	83
Italy .....	93	109	145	134	187
Spain and Portugal.....	83	87	79	82	129
Other parts of Europe.....	97	101	83	82	81

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

## I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

## APPLICATIONS.

7886. T. Norman and H. T. Simpson. Improvements in furnaces to promote combustion. May 22.

8167. G. Moffat and S. Stuttaford. An improved apparatus for consuming smoke and saving fuel in furnaces. May 24.

8168. G. Moffat and S. Stuttaford. Improvements in apparatus for delivering air into the furnaces of steam boilers. May 24.

8192. G. E. Sherwin. Improvements in apparatus for heating, purifying, cooling, distilling, and evaporating water and other liquids. May 27.

8295. B. Versen. Improvements in the production of refractory linings for converter bottoms, and in apparatus therefor. Complete Specification. May 28.

8499. H. Schluzer-Berge and F. Schluzer-Berge. Improvements in air pumps. Complete Specification. June 2.

8523. E. F. Paddon. Improvements in furnaces. June 2.

8527. H. H. Lake.—From K. Müller, Germany. Improvements in air-compressors. June 2.

8544. W. H. Johnson and C. C. Hutchinson. Improvements in filter-presses. Complete Specification. June 3.

8551. C. Eitle. Apparatus for charging retorts. June 3.

8563. W. P. Thompson.—From J. A. Bowden, United States. Improvements in filters. Complete Specification. June 3.

8707. J. von Langer and L. Cooper. Improvements in and connected with gas furnaces for metallurgical and other industrial purposes. June 5.

8790. W. R. Watson and R. A. Robertson. Improvements in apparatus for evaporating, concentrating, and distilling liquids. June 7.

8915. O. Guttman. See Class VII.

9181. The Lucigen Light Co., Lim., and T. M. Jarmain. An oil flame furnace. June 13.

## COMPLETE SPECIFICATIONS ACCEPTED.\*

1889.

9321. F. M. Maynard. See Class XVII.

11,352. R. C. Garton, C. H. Garton, and W. Lawrence. Apparatus for evaporating, distilling, or effecting interchange of heat. June 11.

11,518. A. T. Clarksen and J. B. Spurge. Apparatus for regulating the flow of compressed gases. June 11.

11,600. A. G. Brown. Apparatus for separating water from steam. May 28.

11,865. L. Perkins. Refrigerating and freezing apparatus. June 4.

12,809. W. Maxwell. See Class XVI.

13,343. H. H. Lake.—From Kalle and Co. Transferred to Class IV.

18,153. J. Foster. Vacuum distilling and evaporating apparatus. June 11.

19,539. W. P. Thompson.—From Bordman. Apparatus for reducing mineral fuel, &c. to powder, and supplying same mixed with air to furnaces. June 18.

1890.

6107. J. C. Mewburn.—From C. C. Peck. Evaporation of brine and other solutions, and apparatus therefor. May 28.

## H.—FUEL, GAS, AND LIGHT.

### APPLICATIONS.

7757. C. P. E. Elmann. An apparatus for the production of gas from naphtha and kindred oils. May 19.

7830. B. C. Sykes and G. Blamires. The conversion of solid into gaseous fuel, and its purification. May 20.

7851. R. D. Rowman. Improved process and apparatus for the production of oxygen gas. May 20.

7889. W. Dyson. Improvements in the process of making gas and a product arising therefrom. May 22.

8109. E. Fremd. Improvements in the manufacture of gas. May 23.

8170. W. Clark. An improvement in the manufacture of illuminating gas. May 24.

8274. P. Shuttleworth. Improvements in the manufacture of fire kindlers. May 28.

8294. L. B. Lagoutte and G. de Velna. A process for solidifying mineral oils and applying them for combustion. May 28.

8319. J. C. Jopling. Appliance to increase combustion of gases and smoke in steam boilers. May 29.

8373. E. W. Walker. Improvements in and apparatus for the manufacture of gas for lighting and other purposes. May 30.

8535. S. Pitt.—From E. J. Jerzmanowski, United States. A process and apparatus for the manufacture of illuminating gas. June 3.

8752. W. Cryer. Improvements in means or apparatus for use in producing or separating oxygen and nitrogen gases from atmospheric air, also applicable for manufacturing other gases. June 6.

8909. H. Woodall. Improvements in apparatus for charging inclined gas retorts. June 9.

8930. L. S. d'Izoro. Improved machinery or apparatus for charging and drawing gas retorts. June 10.

8943. W. P. Thompson.—From O. Paternoster, France. Improvements in the manufacture of agglutinants, applicable for use in making coal blocks and other like conglomerates. June 10.

8958. J. Finay. An improved fire lighter, and machinery for manufacturing same. June 10.

9199. J. Bowing. Improvements in the manufacture of fuel from coal slack and similar substances, and in obtaining tar products. June 13.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

10,658. W. P. Thompson.—From A. Mason. Method and apparatus for burning culm or pulverised coal. June 4.

10,659. W. P. Thompson.—From A. Mason. Process and apparatus for burning coal and hydrocarbon fuel. June 4.

13,390. W. Fritsch. Coke ovens. June 18.

1890.

6584. J. J. Shedlock and T. Denny. Gas producers. June 4.

6877. J. J. Hiertz and A. S. Garnett. Combustible coal bricks. June 11.

## III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, ETC.

### APPLICATIONS.

7754. A. H. Allen and W. W. Staveley. Improvements in the production and application of the metallic compounds of phenoloids. May 19.

8728. F. Fenner and F. W. Colls. Improvements in the manufacture of naphthalene, and in means or apparatus employed therein. June 5.

### COMPLETE SPECIFICATION ACCEPTED.

1889.

12,028. J. D. Starck. See Class VII.

## IV.—COLOURING MATTERS AND DYES.

### APPLICATIONS.

7926. J. Y. Johnson.—From F. von Heyden, Germany. The manufacture and production of dioxynaphthalene carbon acids. May 22.

8215. J. Hall. Improvements in the manufacture and production of colouring matter. May 27.

8243. W. R. Lake.—From Wirth and Co., agents for A. Leonhardt and Co., Germany. Improvements in the manufacture of colouring matters. May 27.

8303. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in treating alizarine blue for the obtaining of new compounds thereof, and alizarine blue S. May 28.

8389. A. Remy, R. Kramer, and W. Herking. Improvements in the manufacture of colouring matters or dyes. Complete Specification. May 30.

8411. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture and production of coumarin colouring matters. May 30.

8506. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Production of a yellow colouring matter. June 2.

8530. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the production of azo colours upon fibres. June 2.

8541. J. J. Hart. Improvements in the development or treatment of colouring matters in textile fabrics or materials. Complete Specification. June 3.

8725. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture of new derivatives of alizarine and its analogues. June 5.

8726. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture and production of a new compound, and of artificial indigo from phenylglycecol or analogous compounds, or derivatives thereof. June 5.

8895. R. Holliday and Sons, Lim., and T. Holliday. Improvements in the manufacture of azo colours. June 9.

9001. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture and production of nitroso combinations, and of colouring matters therefrom. June 11.

9080. J. Dawson and R. Hirsch. The manufacture of phenol ether and oxidiphenyl, their homologues and analogues. June 12.

9200. R. W. E. MacIvor. An improvement in the manufacture of ultramarine. June 13.

9258. O. Imray.—From H. K. Marburg, Germany. Improvements in the production of colouring matters. June 14.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

11,666. O. Imray. — From The Farbwerke vormals Meister, Lucius, and Brüning. Production of orange-red colouring matters from flavopurpurine. June 4.

12,031. O. Imray. — From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of dyeing compounds consisting of a mixture of nitrite with basic amido-azo compounds, or with nitro compounds of aromatic monamines in the form of a paste; and application of such paste for diazotising. May 28.

12,191. C. Kolbe. Obtaining carbon acids of meta-amidophenol and its alkyl derivatives. June 4.

13,343. H. H. Lake. — From Kalle and Co. Production of quinazoline derivatives. June 18.

## V.—TEXTILES, COTTON, WOOL, SILK, Etc.

## APPLICATIONS.

7999. W. Gray and W. P. Thompson. Improvements in or appertaining to the separation or purification of cotton seed from its adherent fibre and also of other seeds or grains from external adherent matter or coating. May 22.

8148. J. B. Coleman, W. S. Coleman, and S. E. Coleman. Improvements in the sizing or treatment of lace and the like. May 24.

8296. The Serrell Automatic Silk Reeling Co., Lim. A new or improved process of preparing cocoons for reeling. Complete Specification. Filed May 28. Date applied for April 1, 1890, being date of application in France.

8420. R. C. Anderson. Improvements in the treatment of cloth and other absorbent materials or surfaces. May 30.

8452. E. Knecht. A process for the separation of certain textile fibres from each other. May 31.

8520. P. A. Favier. Improvements in machines for decorticating ramie or other textile plants in a dry or a green state. June 2.

8689. E. Sutcliffe and G. E. Sutcliffe. Improvements in coloured yarns. June 5.

## COMPLETE SPECIFICATION ACCEPTED.

1889.

9904. R. S. Burn. Treating cotton and other fibres preparatory to their being worked up into yarn. June 18.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

## APPLICATIONS.

7786. A. F. S. George. A method of, and apparatus for, colouring and inlaying coloured designs upon and through floor and wall covering materials, and manufacturing the same. May 19.

7787. A. F. S. George. Colouring and inlaying coloured designs upon and through linoleum and other materials. May 19.

7841. H. A. McColl. Improvements in and relating to the printing of designs on handkerchiefs and other piece goods. May 20.

8183. J. M. Campbell. Improvements in colouring, sizing, and otherwise treating paper, and in apparatus therefor, also applicable for filling and treating woven fabrics. May 27.

8238. J. Bell. Improvements in dyeing and finishing of black stiff goods. May 27.

8270. E. Sutcliffe and G. E. Sutcliffe. Improvements in apparatus for washing, dyeing, and treating textile materials. May 28.

8530. B. Willeox. — From The Farbenfabriken vormals E. Bayer and Co., Germany. See Class IV.

8541. J. J. Hart. See Class IV.

8799. A. North. Black piece dyeing for improving the colour of the cotton warp or weft in mixed fabrics of wool and cotton. June 7.

8809. W. L. Wise. — From Favre and Braun, Germany. Improvements in the treatment of fabrics printed or dyed with several colours. June 7.

8896. R. Holliday and Sons, Lim., and T. Holliday. Improvements in the treatment of cotton dyed with certain azo colours. June 10.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

9692. A. Graemiger, W. T. Whitehead, S. Mason, jun., and E. A. Leigh. Machines for dyeing, bleaching, and treating yarn in cop, &c. May 28.

10,360. E. Maertens. Dyeing, &c., yarn or other fibrous material, and apparatus therefor. June 4.

11,098. T. O. Arnfield. Apparatus for dyeing, washing, &c., yarn in hanks. June 18.

11,382. G. B. Sharples. Apparatus for the continuous bleaching, soaping, &c., yarns of cotton, wool, and silk, &c. May 28.

1890.

5285. C. Kellner. Process and apparatus for bleaching vegetable fibres. June 18.

## VII.—ACIDS, ALKALIS, AND SALTS.

## APPLICATIONS.

7764. D. J. Playfair. Improvements in and connected with the obtainment of cyanides and ferrocyanides. May 19.

7983. J. C. Butterfield, T. C. Batchelor, and T. Fairly. Improvements in the manufacture of ammonium nitrate. May 22.

8090. J. D. Pennock and J. A. Bradburn. A new or improved process for manufacturing bleaching powder and caustic soda. Complete Specification. May 23.

8150. J. Leith. Improvements in the treatment of alkali waste, and in the manufacture of sulphuretted hydrogen and sulphide of ammonium, and in the arrangement of plant therefor or connected therewith. May 24.

8332. A. G. Greenway. Improvements in or appertaining to the treatment of galvanisers' waste acids or other similar waste liquors. May 29.

8454. T. H. Williams and W. H. Simons. A solution of calcium phosphate in carbonic acid water. May 31.

8733. W. Bruce. An improved method and plant for the manufacture of carbonic acid gas. June 6.

8786. G. Leon. A new process for the manufacture of fuming and anhydrous sulphuric acid. June 6.

8836. E. Blinkhorn. A process for rendering nitrate of ammonia non-hygroscopic. June 7.

8901. R. H. Davidson and R. H. Davis. Improvements in the treatment of alkali waste for the production of sulphuretted hydrogen. June 9.

8914. A. Crossley and J. W. Jones. Improvements in the process of, and apparatus for, producing ferro-ferrie and ferrie oxides. June 9.

8915. O. Guttman. Improvements in apparatus for the condensation of nitric acid and other distillation products. Complete Specification. June 9.

8942. J. Leith. Improvements in or connected with the manufacture of sulphuretted hydrogen and sulphide of ammonium and of alkali, and in the arrangement of plant therefor. June 10.

9112. F. Ellershausen. Improvements in the manufacture of caustic soda. June 12.

9198. W. L. Wise.—From The Chemische Fabrik Buckau Actiengesellschaft, Germany. Treatment of impure or waste potassium salts for the manufacture therefrom of soda, potash, hydrochloric acid, magnesia, gypsum, and sulphur or sulphuric acid. June 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

12,028. J. D. Starek. Process and apparatus for the production of fuming sulphuric acid or sulphuric anhydride, from the residues of the petroleum, paraffin, and tar industry. June 4.

13,264. J. Farmer. Manufacture of acetic acid and apparatus therefor. June 18.

1890.

4095. E. Bergmann. Production of cyanide compounds from ferrocyanide compounds. June 18.

### VIII.—GLASS, POTTERY, AND EARTHENWARE.

#### APPLICATIONS.

7822. D. Y. Cliff. Improvements in the means of effecting correct designs in decorative tiles. May 20.

7849. J. A. Jobling. Improvements in pots for melting glass. May 20.

8917. C. T. Maling. Improvements in the manufacture of china or earthenware mugs, jugs, and other vessels. June 9.

8977. J. Jacobs. Improvements in and relating to illuminating tiling. Complete Specification. Filed June 10. Date applied for December 12, 1889, being date of application in United States.

9172. R. J. Withers. Improvements in roof and hanging tiles. June 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

9841. F. C. Clare. Manufacture of terra-cotta porcelain castor bowls, &c. June 4.

11,979. H. H. Lake.—From A. Gilbert. Enamelling articles of copper. May 28.

13,577. M. Sugar.—From C. Lasalle and C. Mautter. Ornamenting glass. June 18.

1890.

6231. A. Fielding. Kilns for firing or hardening pottery. May 28.

### IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

#### APPLICATIONS.

7942. E. H. Edwards. Improvements in construction and working of cement kilns. May 22.

7962. R. Watkins. The utilisation of slate or slate refuse for making Portland cement. May 22.

8033. G. H. Skelsey. Improved means for the removal of the free lime and heat in newly-ground cement. May 22.

8108. F. Sarg. Improvements in concrete to be used in the construction of vaults, roofs, arches, floors, and the like. May 23.

8355. W. E. Keevil. Improvements in the treatment of Fuller's earth and in apparatus therefor. May 29.

8413. J. Hartnell. Improvements in the manufacture of artificial stone. May 30.

8519. O. Prinz. Improvements in the manufacture and treatment of cement. June 2.

8606. S. G. T. C. Bryan. Improvements in the treatment of slag for a variety of important uses, such as building blocks, paving blocks, &c. June 3.

8723. G. Ollier. Improvement in or relating to fire-resisting cements. June 5.

8801. J. D. Carr. An improved material or composition for covering walls, and for other decorative and useful purposes. June 7.

8919. D. Wilson. Improvements in apparatus for use in the manufacture of cement, and improvements connected with the said manufacture. June 9.

8993. V. L. Daguzau. A new or improved cementing material. June 10.

9239. D. Hart. Improvements in bricks for building purposes. Complete Specification. June 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1890.

4741. W. A. Gibbs. Cement kilns. May 28.

4995. G. A. Mansfield. Improvements in paving. June 18.

6855. G. Higham. Composition for use in connexion with the manufacture of Portland cement. June 11.

### X.—METALLURGY, MINING, Etc.

#### APPLICATIONS.

7820. F. G. Bates. Improvements in, and preparation of, materials for use in converting iron or low steel into high grade steel by the cementation process. Complete Specification. May 20.

7827. S. Fox. The application of water-gas to the manufacture of iron and steel in connexion with Siemens' and other gas furnaces. May 20.

7916. F. T. Thomas. An improved method of pickling and cleaning metal plates and sheets, and apparatus therefor. May 22.

8005. H. H. Lake.—From H. T. Smith, United States. Improvements relating to the formation of ingots for the manufacture of plated wire. May 22.

8032. W. H. Dowland. Improvements in the recovery of gold and silver by means of chlorine. May 22.

8295. B. Versen. See Class I.

8324. H. L. Wethered and A. E. Morgans. An improved method of and apparatus for recovering mercury and amalgam after treatment with mercury of gold and silver ores. May 29.

8352. W. McDermott. Improvements in apparatus for concentrating or separating ores and other substances. May 29.

8357. S. O. Cowper-Coles. Improvements in coating metallic surfaces with tin. May 29.

8399. H. Aitken. Improvements in means for the treatment of iron ores containing hydrocarbons, carbon, nitrogen, or sulphur. May 30.

8572. T. L. Thomas and J. B. Hillman. Improvements in or relating to the art or process of galvanising metal tubes, bars, plates, castings, ornamental ironwork, and other articles, and in means or appliances for use therein or relating thereto. June 3.

8606. S. G. T. C. Bryan. *See Class IX.*
8655. E. C. Miller.—From The Magnolia Anti-friction Metal Co., United States. Improved manufacture of compositions or alloys for anti-friction purposes. Complete Specification. June 4.
8707. J. von Langer and L. Cooper. *See Class I.*
8759. J. von Langer. Improvements in the manufacture of iron and steel. June 6.
8820. J. Clark and G. W. Clark. Obtaining alloys of aluminium with other metal or metals. June 7.
8826. J. Coombs. Improvements in gold extraction. June 7.
8867. W. Beardmore. Improvements in the manufacture of armour plates. June 9.
8884. J. W. MacFarlane. A method of extracting gold from auriferous ores by an improved process of amalgamation. June 9.
8900. J. C. Butterfield. Improvements in the treatment of sulphurised ores. June 9.
8908. F. G. Jordan. Improvements in the process of, and machinery for extracting gold from refractory ores. June 9.
8916. P. Ellershausen. Improvements in the extraction of metallic lead from ores containing the same. June 9.
8922. T. Peters. A process for the application of iron residues which result from the reduction of organic nitro-compounds. June 9.
8929. S. O. Cowper-Coles. Improvements in coating metallic surfaces with alloys. June 10.
8989. H. H. Lake.—From G. W. Cummins, United States. An improved process for treating copper and its alloys to prevent oxidation and deoxidation thereof during heating and annealing. Complete Specification. June 10.
8991. H. H. Lake.—From J. D. Brown, United States. Improvements relating to the manufacture and treatment of iron and steel, and to compounds for use therein. Complete Specification. June 10.
8992. H. W. Lash and J. Johnson. Improvement in the reduction of ore. Complete Specification. June 10.
9115. R. D. Bowman and H. J. Anderson. Process for the treatment of ores containing precious metals. June 12.
9123. A. Dauber. Improvements in making iron of any quality, pig iron, wrought iron, cast steel, rough steel. June 12.
9171. H. J. Smith. Improvements in and relating to the production of castings in ingot iron, steel, and other metal. June 13.
9182. C. R. Western. Improved means and apparatus for extracting gold and other precious metals from their ores. June 13.
9247. E. Edwards.—From E. Honold, Germany. Improvements in apparatus for and process for desilverising lead. June 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

6882. F. Knowles.—From T. C. Sanderson. Separation of gold from antimony. June 4.
8678. M. R. Couley and J. H. Lancaster. Apparatus for deoxidising, dephosphorising, desulphurising iron and other ores, and collecting and burning the gases therefrom. June 4.
9301. J. Gill. Blast furnaces. June 4.
- 10,279. R. E. Evenden. Apparatus for washing and separating gold and other minerals. May 28.
- 11,393. T. Parker. Manufacture of iron and steel. June 18.
- 11,707. T. Parker and A. E. Robinson. Manufacture of sodium, potassium, and magnesium. May 28.

- 11,882. S. Trivick. Roasting certain ores to obtain metals therefrom, and apparatus therefor. June 4.
- 11,883. S. Trivick. Extracting precious metals from their ores, and apparatus therefor. June 18.
- 12,113. C. L. Bath. Apparatus for forming copper ingots. June 4.
- 12,500. T. Twynam. Manufacture of iron and steel. June 11.
- 12,648. J. Clark. Obtaining alloys of aluminium with other metals. June 11.
- 12,811. T. Hydes and S. W. Wilkinson. Apparatus for casting molten metal, slag, &c. into pigs and blocks. June 18.
- 12,839. J. C. Bromfield. Manufacture of iron and steel, and utilisation thereof of waste products. June 18.
- 19,759. J. T. Penny and W. H. Richardson. Apparatus for triturating and amalgamating gold, silver, and other ores. June 11.

1890.

237. R. Brown and G. H. Irvine. Process and apparatus for extracting gold by the wet method from finely divided quartz ores, &c. June 11.
1794. C. Pfeiffer. Amalgamator for extraction of gold and silver from the ore by the action of mercury. June 18.
5003. A. K. Eaton and K. A. Vanderbilt. Obtaining chromium and chromium alloys. June 18.
5659. G. W. Marble and M. W. Simons. Forging metals, and machinery therefor. June 18.
5894. A. J. Boulton.—From J. W. Bookwalter. Converters. May 28.
6529. J. H. Bramwell. Hardening steel. June 4.
7461. H. H. Lake.—From The Russel and Erwin Manufacturing Co. Annealing metals. June 18.

#### XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

##### APPLICATIONS.

7853. W. P. Thompson.—From C. L. Coffin, United States. Improvements in welding metals electrically, and apparatus therefor. Complete Specification. May 20.
7876. H. H. Lake.—From E. A. Colby, United States. Improvements in methods of and apparatus for melting, refining, and casting metals and other substances by electricity. Complete Specification. May 20.
7988. C. L. Coffin. Improvements in welding metals electrically. Complete Specification. Filed May 22. Date applied for November 6, 1889, being date of application in United States.
7989. C. L. Coffin. Improvements in welding metals by electricity. Complete Specification. Filed May 22. Date applied for November 12, 1889, being date of application in United States.
7990. C. L. Coffin. Improvements in electric welding. Complete Specification. Filed May 22. Date applied for November 19, 1889, being date of application in United States.
7991. C. L. Coffin. Improvements in electric welding. Complete Specification. Filed May 22. Date applied for November 19, 1889, being date of application in United States.
7992. C. L. Coffin. Improvements in electric welding. Complete Specification. Filed May 22. Date applied for November 19, 1889, being date of application in United States.
7993. C. L. Coffin. Method of welding metals electrically. Complete Specification. Filed May 22. Date applied for December 6, 1889, being date of application in United States.

7994. C. L. Coffin. Method of welding metals electrically. Complete Specification. Filed May 22. Date applied for December 12, 1889, being date of application in United States.

8086. M. Bailey and J. Warnes. Improvements in secondary batteries. May 23.

8233. W. A. A. Dowden. The extraction of gold from its ores, consisting of a form of copper plate amalgamated with mercury, the action of which in retaining the gold upon it is aided by the passing of a current of electricity. May 27.

8242. W. R. Lake.—From H. Lemp, United States. Improvements in and relating to electric welding or metal working apparatus. Complete Specification. May 27.

8254. R. Haddan.—From F. Pescetto, Italy. Improvements in the manufacture of plates for electric accumulators. May 27.

8394. W. Wright. Improvement in battery compound. May 30.

8442. Sir C. S. Forbes, Bart. Improvements in primary batteries and in apparatus connected therewith. May 31.

8469. The Mining and General Electric Lamp Co., Ltd., and D. G. FitzGerald. Improvements in or connected with voltaic battery elements. May 31.

8534. N. de Benardos and Lloyd. Improvements in secondary batteries or electrical accumulators. June 2.

8578. J. Y. Johnson.—From C. Hering, France. Improvements in electrical accumulators or secondary batteries, and in the manufacture and production of plates or elements therefor. Complete Specification. June 3.

8703. W. P. Thompson.—From C. L. Coffin, United States. Improvements in electric welding. Complete Specification. June 5.

8716. E. Edwards.—From T. Lange, Germany. A new or improved process for obtaining, by electrical decomposition, metallic zinc from solution of sulphite of zinc. June 5.

8800. W. P. Thompson.—From I. Pearl, Spain. Improvements in or relating to electric accumulators. June 7.

8933. G. H. Felt. Improvements in the method of and apparatus for depositing metals by electro-deposition. Complete Specification. June 10.

9030. C. H. Freedman. Primary battery for open circuit work. June 11.

9257. S. Wohle. Process for effecting electrolytic deposit of aluminium. June 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

11,528. C. Beyer and G. Hagen. Electrodes for accumulators. June 18.

12,906. E. Hermite, E. J. Paterson, and C. F. Cooper. Electrolytic treatment of vegetable matters for the production of starch. June 18.

14,162. A. de Méritens. See Class XVII.

1890.

2302. H. Weymersch and R. McKenzie. Electric batteries working with two liquids or electrolytes. June 18.

3924. H. H. Lake.—From The Crosbig Electric Co. Electric batteries. June 18.

4087. H. T. Cheswright. Secondary voltaic batteries. June 11.

7383. J. N. Levens. Battery element. June 18.

7444. A. Million and P. Bony. Galvanic batteries. June 18.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

### APPLICATIONS.

7851. A. W. Rhenstrom. Improvements in the manufacture of soap. Complete Specification. May 20.

7891. T. H. Olyer. Hop soap. May 22.

7976. A. T. Hall. Improvements in refining vegetable oils. May 22.

8077. G. Allen. Improved composition of soap. Complete Specification. May 23.

8123. C. R. Hingworth. Improvements in soaps for skin disease. May 24.

8470. J. B. Koenig. Manufacture of soap combined with mineral oils. May 31.

8484. W. B. G. Hogg and J. G. Lorrain. A method of and apparatus for purifying oils and fatty substances. May 31.

9062. C. D. Hestrom. Improvements in the separation of fats from emulsions. Complete Specification. June 11.

9176. H. H. Lake.—From F. de la Croix, Belgium. Improvements in apparatus for desiccating and sterilising waste animal substances, and for extracting fat therefrom. June 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1890.

4809. J. Y. Johnson.—From M. Duclos. Manufacture of soap and glycerin. May 28.

5375. E. Noppel, B. Grosche, and J. Bigler. Apparatus for refining oil. June 11.

## XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

### APPLICATIONS.

8250. G. L. Hille. Improvements in the treatment of waste india-rubber and in apparatus therefor. May 27.

8668. B. Piffard. Improvements in the manufacture of varnishes. June 4.

9108. S. Springer and J. R. R. Hawkins. A protective compound. June 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

8513. T. Hughes. Method and means for protecting submerged structures from effects of moisture, applicable also to construction and decorations of buildings. May 28.

12,292. R. Condy. A new compound to be used in paint or pigment. June 4.

12,756. R. Dick. Preparing and treating gutta-percha compounds. June 18.

1890.

5387. D. Fulton.—From D. F. Schmid. Anti-corrosive compound. June 4.

## XV.—AGRICULTURE AND MANURES.

## APPLICATIONS.

7890. W. Dyson. A new composition for tillage purposes. May 22.

8064. R. Fullarton. Improvements in treating or purifying phosphatic minerals. May 23.

8262. Sir E. R. Sullivan, Bart. Improvements in the manufacture of manures. May 27.

9129. H. H. Lake.—From A. Nenninger, United States. Improvements relating to the manufacture of acid phosphates for use as artificial manure. Complete Specification. June 12.

## XVI.—SUGARS, STARCHES, GUMS, Etc.

## APPLICATION.

8029. E. Stieger, E. Schulze, and C. Auer-Schollenberger. An improved process for treating vegetable cellular membranes with the object of obtaining glutinous substances. May 22.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

12,021. A. Chapman.—From C. A. Matthey. Process and apparatus for extracting sugar from sugar-cane, &c. June 4.

12,809. W. Maxwell. Multiple-effect apparatus for concentrating sugar juice, &c. June 18.

## XVII.—BREWING, WINES, SPIRITS, Etc.

## APPLICATIONS.

7878. F. König. Improved process of fermentation, and means and apparatus therefor. May 20.

7880. H. T. Brown, G. H. Morris, and E. R. Moritz. A process for preparing raw grain or other amylaceous substances for mashing in brewing or distilling operations. May 20.

8408. A. Walker. The improved mode of treating the wash in distilleries. May 30.

8850. E. J. Taylor. Improvements in the manufacture of whisky and other spirits. June 7.

9183. C. R. C. Tichborne, A. E. Darley, M. F. Pureell, and S. Geoghegan. Method of and appliances for the collection and utilisation of the carbonic acid gas and other products given off during the process of all fermentations. June 13.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

9321. F. M. Maynard. Valve, &c. for regulating flow of steam or liquids, especially for use with brewers' attenuators. June 11.

10,740. E. Larsen. Facilitating the drying of distillers' spent wash and similar matter. May 28.

10,891. J. Sleeman. Method of malting grain, and apparatus therefor. June 11.

12,186. P. C. Rousseau, M. J. de Chanterae, and M. J. D. A. de la Baume. Purifying alcohol, wine, and other alcoholic liquids. June 4.

12,187. L. Lederer. Manufacture of yeast. June 11.

13,054. L. Meyer. Producing ferments. June 4.

14,162. A. de Méritens. Treating and rectifying or ageing alcohol or alcoholic liquors by electricity. June 4.

1890.

3579. C. Hof.—From L. Rubsam. Production of malt. June 4.

6480. G. Schneider. Producing and storing beer without contact with the atmosphere. June 11.

6587. W. T. Whiteman.—From F. Ilawek. Process and apparatus for distillation and rectification of alcohols. June 18.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

## APPLICATIONS.

*A.—Chemistry of Foods.*

7551. A. W. Stokes. Improvements in the means of obtaining acidity or alkalinity in milk or other substances. June 3.

8018. J. White. The manufacture of a jelly powder. Complete Specification. May 22.

8354. W. C. H. Jessen. Improvements in preserving eggs. Complete Specification. May 29.

8804. W. H. Gover. Improvements in and connected with the manufacture of substances of food, especially relating to the manufacture of bread, bismits, cakes, infants' food, viz., hygienic phosphated food, bread, &c. June 7.

*B.—Sanitary Chemistry.*

7840. W. C. Young. Improvements in the purification of water by distillation. May 20.

7963. J. W. Lodge. Improvements in the method of, and apparatus for, purifying or treating river and sewage water, and recovery of solid matter found therein. May 22.

8239. W. S. West. Improvements in and relating to apparatus for handling and treating sewage. Complete Specification. May 27.

8498. J. Macfarlane and O. Prescott Macfarlane. The treatment of sewer gas and sewage. June 2.

8685. J. Chaffer and L. Simms. An improved method of and means for purifying sewage and other impure matters. June 5.

9203. A. R. Millbourn. The separation and recovery of all the component parts of various waste products. June 14.

*C.—Disinfectants.*

8838. D. C. Mackenzie. An absorbent deodorising and disinfecting powder for a boot and shoe powder, toilet, and other purposes. Complete Specification. June 7.

8938. E. Leman. An improved compound for preserving meat, fish, and poultry. June 10.

8997. G. Walker. Improvements in the preparation of disinfectants for more convenient transmission, carriage, storage, and general application. June 10.

9103. J. Y. Johnson.—From F. von Heyden, Germany. Improvements in the manufacture of disinfectants or antiseptics. June 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

*A.—Chemistry of Foods.*

1890.

6421. A. G. Cunningham. Bread for dyspeptics. June 18.

*B.—Sanitary Chemistry.*

1889.

11,798. C. J. Moor. Treatment of sewage for purification and production of valuable substances. June 4.

## XIX.—PAPER, PASTEBOARD, Etc.

## APPLICATIONS.

7761. R. A. Sloan and J. E. L. Barnes. Improvements in machinery for the manufacture of wood fibre or wood wool. May 19.

7816. J. A. Loudon. The treatment of peat fibre for the manufacture of brown paper, wrappers, millboards, &c. May 20.

7971. F. W. Crowther. A new or improved metallic foil coated airtight and grease-proof paper. May 22.

8422. O. Evenstad and O. Senstad. Improvements in apparatus for use in the manufacture of wood-wool. Complete Specification. May 30.

8504. F. Butterfield and W. Renton. Improvements in the method of and apparatus for finishing paper. June 2.

8553. J. Hawke. Improvements in the manufacture of copying paper. Complete Specification. June 3.

9051. J. Luke. Improvements in and relating to the manufacture of paper for mill wrappers, lappings, boxes, and such like, and in machinery connected therewith. June 11.

9135. J. Craig. Improvements in the manufacture of paper. June 13.

## COMPLETE SPECIFICATION ACCEPTED.

1890.

4960. C. Kellner. Process and means for purifying paper pulp. June 18.

## XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

## APPLICATIONS.

8193. W. S. Wardle. Improvements in photography. May 27.

8214. M. A. Wier. New or improved means for developing photographic films in actinic light. May 27.

9218. F. W. Hayward. Improvements in colouring and softening photographs on paper. June 14.

## COMPLETE SPECIFICATIONS ACCEPTED.

1890.

6028. P. Rudolph. Photographic objectives. May 28.

6029. E. Abbe and P. Rudolph. Photographic objectives. May 28.

## XXII.—EXPLOSIVES, MATCHES, Etc.

## APPLICATIONS.

7839. W. Cross. Improvements in the manufacture of matches, and in boxes therefor. May 20.

8181. P. Ward and E. M. Gregory. An improved priming and detonating composition. Complete Specification. May 31.

8717. E. Binkhorn. New or improved manufacture of explosives suitable for use in lieu of fulminate of mercury or the like for detonating purposes. June 5.

8811. H. Koff. Improvements in the manufacture of gunpowder. June 7.

8843. E. Muller. An apparatus for nitrifying cotton, cellulose, straw, and similar material. Complete Specification. June 7.

9197. P. P. Alexander. Improvements in electrical fuses. June 13.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

11,664. Sir F. A. Abel and J. Dewar. Manufacture of explosives. May 28.

11,667. Sir F. A. Abel, J. Dewar, and W. Anderson. Process and apparatus for manufacturing explosives in the form of wires or rods and forming same into cartridges. June 18.

## XXIII.—ANALYTICAL CHEMISTRY.

## COMPLETE SPECIFICATION ACCEPTED.

1889.

18,856. A. W. Gerrard. Apparatus for estimating the quantity of glucose or grape sugar in fluids. June 4.

## The Society of Chemical Industry.

### Past Presidents:

Sir H. E. Roseoe, M.P., LL.D., V.P.R.S. ....	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S. ....	1882—1883.
Walter Weldon, F.R.S. ....	1883—1884.
W. H. Perkin, Ph.D., F.R.S. ....	1884—1885.
E. K. Muspratt ....	1885—1886.
David Howard ....	1886—1887.
Prof. James Dewar, F.R.S. ....	1887—1888.
Ludwig Mond ....	1888—1889.
Sir Lowthian Bell, Bart., F.R.S. ....	1889—1890.

## COUNCIL FOR YEAR ENDING JULY, 1891.

*President:* E. Rider Cook.

### Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond.
R. Forbes Carpenter.	Dr. Hugo Müller, F.R.S.
Prof. James Dewar, F.R.S.	B. E. R. Newlands.
James Duncan.	Dr. W. H. Perkin, F.R.S.
David Howard.	Dr. Edw. Schunck, F.R.S.
S. H. Johnson.	J. C. Stevenson, M.P.

### Ordinary Members of Council:

A. H. Allen.	Prof. R. Meldola, F.R.S.
L. Archbutt.	E. K. Muspratt.
S. B. Boulton.	T. L. Patterson.
Jno. Brock.	Jno. Pattinson.
Jno. Calderwood.	Jno. Spiller.
H. Grimshaw.	T. W. Stuart.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

### Honorary Foreign Secretary:

Dr. Ferdinand Harter.

*General Secretary:* Charles G. Crosswell.

### Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

## THE JOURNAL.

### Publication Committee:

The President.

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	Ivan Levinstein.
Joseph Bernays, M.I.C.E.	Prof. R. Meldola, F.R.S.
H. Brunner.	Ludwig Mond.
W. Lant Carpenter.	E. K. Muspratt.
Prof. Frank Clowes, D.Sc.	B. E. R. Newlands.
W. Y. Dent.	C. O'Sullivan, F.R.S.
Prof. Jas. Dewar, F.R.S.	John Pattinson.
John Heron.	W. H. Perkin, Ph.D., F.R.S.
D. B. Hewitt, M.D.	Sir H. E. Roseoe, M.P., F.R.S.
David Howard.	John Spiller.
Prof. E. J. Hummel.	A. Norman Tate.
	Thomas Tyrer.

### Editor:

Watson Smith, University College, London, W.C.

## NOTICES.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Society's Office will be closed from the 5th to the 16th August inclusive.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

#### MEMBER ELECTED, 9th JULY, 1890.

Mendeleeff, Prof. D., St. Petersburg, professor of chemistry.

#### LIST OF MEMBERS ELECTED, 23rd JULY, 1890.

Bairstow, John, 32, Sealand Road, Chester, chemical works manager.

Brierley, J. T., 249, Bolton Road, Chorley, Lancashire, analytical chemist.

Clark, Franklin S., 527, Madeira Avenue, New York City, U.S.A., manufacturing chemist.

Devey, Arthur C., c/o La Société Hermite, 4, Rue Drouot, Paris, bleacher.

Donald, Saml., Corporation Gasworks, Dalmarnock Road, Glasgow, analytical chemist.

Frankenstein, L., 32, Dover Street, Oxford Road, Manchester, india-rubber manufacturer.

Frusher, T., White Abbey Dye Works, near Bradford, Yorks, master dyer.

Goodall, Geo., 182, Mansfield Road, Nottingham, hosier.

Goulding, W. J., 25, Eden Quay, Dublin, fertiliser manufacturer.

Harris, Sydney J., Mechanics' Institute School of Science, Leeds, head master.

Hodgson, Wm., 8, Victoria Buildings, St. Mary's Gate, Manchester, oil broker.

Johnson, Robt. W., New Brunswick, N.J., U.S.A., manufacturing chemist.

Kirkland, John, 42, Eland Road, Lavender Hill, S.W., bread works manager.

Mond, Alfred M., Winnington Hall, Northwich, analytical chemist.

Santer, Ernest H., 176, High Street, Redcar, Yorks, analytical chemist.

Thomson, W. T., 156, Bath Street, Glasgow, analytical chemist.

#### CHANGES OF ADDRESS.

Allan, John, 1/o Harringay; 2, Crane Court, Fleet Street, E.C.

Allen, Wm. N., 1/o London; 2, Chesnut Street, Philadelphia, Pa., U.S.A.

Bartlett, F. L., 1/o Portland; Canon City, Colorado, U.S.A.

Beckett, J. H., 1/o Wilmslow; Corbar Hill House, Buxton.

Bernard, Jas., 1/o Glasgow; Tinoen, Lim., Casal das Rollas, Poco do Bispo, Lisbon.

Brown, R. J., 1/o Davenport; Technical School, Stockport.

Carmody, Prof. P., 1/o Somerset House; Government Laboratory, Port of Spain, Trinidad.

Chamberlain, Jno., 1/o Melbourne; Brunswick Gasworks, near Melbourne, Victoria.

Elmore, A. S., 1/o Rothwell; Spring Grove, Low Road, Hunslet, Leeds.

Fletcher, R. Steele, 1/o Abbey Walk; c/o Fletcher Bros. and Co., Grimsby.

Griffith, D. Agnew, Journals to c/o Cowan and Son, Hammersmith Bridge Works, Barnes, S.W.

Hailes, A. J. de, 1/o Hornsey; 92, Manor Road, Stoke Newington, N.

Horton, Wm., 1/o Edge Lane; 38, Belvidere Road, Prince's Park, Liverpool.

Humphries, Jacob, 1/o Low Moor; c/o Humphries and Co., Edward Street, Rochdale.

Kent, W. J., Journals to P.O. Box 1812, Johannesburg, S.A.R.

Lyle, Jno., 1/o 37; 21, Mining Lane, London, E.C.

Redwood, Htyd J., 1/o Walthamstow; 141, Kent Street, Brooklyn, N.Y., U.S.A.

Saint, W. J., 1/o Erlangen; 11, Queen's Road, Aberdeen.

Saito, K., 1/o Yeisei Shikenjo; Nishiku Yedobori Shimo, Dori Sauchiome, Osaka, Japan.

Salis-Mayenfeld, Dr. E. von, 1/o Clayton; c/o Hohenhausen and Co., Lim., Blackley, near Manchester.

Waché, Alf., 1/o Roubaix; 27, Rue Morel, Donai, France.

Walker, J. S., 1/o Morningside Road; 5, Keir Street, Lauriston, Edinburgh.

Whalley, L. J. de, 1/o Westcombe Park; 26, Park Place, Greenwich, S.E.

#### CHANGE OF ADDRESS REQUIRED.

Huy, Alex., 1/o Kirby House, Arboretum Avenue, Lincoln.

#### Death.

T. R. Ogilvie, 1/o Mill Lane House, Plymouth, at Melbourne.

## PROCEEDINGS

OF THE

## NINTH ANNUAL MEETING.

THE Annual General Meeting of the Society was held on Wednesday, the 9th July, in the Chemical Lecture Theatre of University College, Nottingham.

The President, Sir LOWTHIAN BELL, took the Chair at 11 o'clock, and called upon the General Secretary to read the Minutes of the last Annual Meeting. The Minutes having been duly confirmed—

The Mayor (Alderman GOLDSCHMIDT) said it afforded him much pleasure to offer the Society a hearty welcome to Nottingham. He hoped that the meeting would be a successful one in every respect, and that the members would carry away none but pleasant recollections of their visit.

The President said that it was a great pleasure to him to offer the hearty thanks of the members present for the very kind welcome which had been extended to them. His own recollection of Nottingham carried him back to 25 years ago, since which time he had not had the pleasure of being in the town. On that occasion he had enjoyed the hospitality of the then Mayor, and from the lively recollection which he had preserved of that visit he had no doubt that the pleasure which he had then experienced would be repeated on the present occasion. He wished to tender to the Mayor and Corporation the thanks of the members, not only for his kind words of welcome, but also for the vigorous measures (which he had no doubt would prove successful) that had been taken to conduce to their pleasure.

The Mayor then left the meeting.

Dr. C. R. ALDER WRIGHT moved: that Messrs. S. V. Holgate and E. N. Butt be appointed scrutators. The motion was seconded by Mr. T. Tyrer, and carried unanimously.

The ballot was then declared closed.

The President then called upon the General Secretary to read—

## THE REPORT OF THE COUNCIL.

The Council has the honour to report that the membership of the Society has increased from 2,445, as reported at the last meeting, to 2,595, or a net increase of 150 members. During the year 298 members have been elected, and 148 have been removed by death, resignation, and other causes.

During the past session 73 papers and 14 communications have appeared in the Journal as against 55 papers and 5 communications the year before. To the authors of these the Council would offer its best thanks.

The Journal is now recognised as the leading authority on Applied Chemistry in the English language, and forms an admirable work of reference. The number of subjects treated under the 23 headings of the Journal and Patent Literature amounts at present to about 60, and is not likely to increase much in the future. Attention will now be devoted to the consolidation and perfection of each group in order that the specialist may find there a full and complete record of contemporary work.

On the 23rd June last the Treasurer reported the sum of 1,720*l.* 6*s.* in the bank, as against 1,214*l.* 4*s.* 5*d.* a year ago. The investments of the Society remain as last year, viz. 3,688*l.* 15*s.* 9*d.*; but it is intended to add to this sum shortly 165*l.*, derived from 11 Life Composition Fees, which

have been received during the last two years. The revenue last year, as will be seen from the Treasurer's report, exceeded the expenditure by 607*l.* as against 918*l.* 14*s.* 9*d.* in 1888, but this reduction was foreseen last year. It is mainly due to diminished returns from advertisements and increased expenditure upon the Journal, which is money well spent.

The Council has the pleasure to announce that, in constituting the permanent governing body of the Imperial Institute, the interests of the chemical industries have not been passed over, and the appointment of one member has been allotted to the Council of this Society.

Mr. E. K. MUSPRATT, in moving the adoption of the report, said that he was glad to see that the Society continued to prosper, and he hoped that the coming year would bring it even greater prosperity than that shown by the present report.

Professor CLOWES seconded the motion, observing that the report must be felt to be eminently satisfactory. It showed progress, which was all that could be desired. The motion having been carried unanimously,

The Hon. Treasurer (Mr. E. RIDER COOK) presented the accounts for the year, printed on page 690. In doing so he said that the printed figures would speak for themselves, and that all he need do was to add a few words supplementary to what had been said in the Annual Report of the Council as to the increase in the membership. That increase was a practical one, for he had already received 2,259 subscriptions as against 2,152 at the same date last year, and as against 2,233 for the whole of 1889, so that he had already in hand 26 more subscriptions than the total for last year. He would, however, warn the members that, the Council having taken a somewhat extravagant fit as regarded expenditure, they must not expect to find in the coming year a surplus equal to that shown in the accounts now presented. If he could contrive to save 600*l.*, he was satisfied that it would be due to the large increase in the membership, and not to a decrease in the expenditure. He was glad to be able to say that members had taken the hint he had given last year with respect to sending receipts for subscriptions by return of post; and although the commencement of the current year had brought him the usual rush of work, he was thankful to say that members had forborne to complain of the consequent delay in getting their receipts.

The PRESIDENT, in moving the adoption of the accounts and a vote of thanks to the Hon. Treasurer, said that he wished to say a few words in commendation of the Hon. Treasurer's report. It was not often that a Society was fortunate enough to possess a treasurer who would bear admonition and act upon it in the conscientious way that Mr. Rider Cook had done. He would not like to measure the utility of such an establishment as the Society of Chemical Industry by the amount of money it had in the bank. He did not by any means wish to have an overdrawn account, but he believed that any balance they might have would be most usefully employed in helping to perform the functions of the Society; and unless there should be a prospect of requiring a large sum of money for some immediate purpose, such as building a palace for the Society, the best thing they could do with their revenue was to spend it for the benefit of the present members.

Mr. L. ARCHBUTT (in the unavoidable absence of Sir John Turney) seconded the motion, which was carried by acclamation.

The PRESIDENT then said that no one who took the trouble to examine the result of the labours of the Council and of the Society could fail to be impressed with the high honour which was involved in being appointed to fill the office which had fallen to his lot. Under these circumstances he was sure that the meeting would excuse him for trespassing upon their time in order that he might express his thanks to his colleagues and the members generally for having appointed him to fill the post of President during the past year.

Table I. contains consumptions of materials and generally the conditions under which the different furnaces, therein specified, were working.

The manner in which the heat was generated is given in Table II. at the end of the address, where also the calorific value of each unit of fuel is shown.

In Table I. is inserted the number of calories considered as absorbed by each item in the process. Different observers have given the results of their experiments undertaken with the view of obtaining the quantity of heat required for the purposes against which they are placed in the *Appropriation* account. The actual figures, being more or less an average, are as follows:—

	Calories.
Reduction of peroxide of iron.....	1,780
Dissociation of CO reckoned on C precipitated.....	2,400
Fusion of pig iron .....	330
Evaporation of water in coke.....	540
Decomposition of water, reckoned on H .....	34,000
Expulsion of CO <sub>2</sub> from limestone .....	370
Decomposition of this CO <sub>2</sub> in limestone reckoned on C present	3,200
Fusion of slag .....	330

Carried off in gases—estimated from weight, temperature, and specific heat.

Balance—to include loss by radiation, convection, &c.; by heat in tuyere water, &c.

The specific heat of the escaping gases is averaged in all cases at  $-24^{\circ}\text{C}$ .

Do. do. blast is taken at 237.

Heat evolved by the oxidation of carbon is taken at as follows:—

	Calories.
C to CO .....	2,400
C to CO <sub>2</sub> .....	8,000
C in CO to C as CO <sub>2</sub> .....	5,600

G represents a furnace working on English hæmatite ore, inserted as a comparative test of general correctness of mode in the other calculations.

## THE SMELTING OF IRON ORES CHEMICALLY CONSIDERED.

BY

SIR LOWTHIAN BELL, BART., F.R.S.

---

### INTRODUCTORY.

It is only natural, in a Society occupying itself with chemical industry, that the subjects referred to in a presidential address should be largely dealt with from a chemical point of view. Fifty years ago, when I was commencing my manufacturing career, the choice of subjects would have been comprised within a comparatively narrow compass, not so much from the smaller extent of this country's industrial pursuits, as from a supposed want of connection between some of them and the science of chemistry. The manufacture of iron was one of these. I recollect my disappointment in travelling among the furnaces and mills at home and abroad, to hear so little importance attached to the studies to which I had been applying myself for some time in Edinburgh and in Paris. Notwithstanding this indifference on the part of the ironmasters themselves, men of science, particularly in Germany and France, had devoted much attention to those branches of knowledge more directly bearing on metallurgical questions. Behind both these nations in that sphere of learning, which our Society and others are now doing their best to advance, were the iron manufacturers of our own country. It is a little remarkable, however, that during the half century we are considering, Great Britain in point of production and in manufacturing invention and proficiency, occupied the foremost rank as an iron-making country.

If we take an article like soda ash, an undoubted chemical product in the popular sense of the word, we find it may contain, besides sodium carbonate, 15 per cent. of foreign matter, without, for most purposes to which it is applied, the commercial value of its alkali being seriously impaired. If, however, pig iron has notably above one part of phosphorus in two thousand, 0.5 per cent., it would be rejected by the Bessemer steel maker as unsuitable for his purpose. Cases of this description, proving the extraordinary effects of minute quantities of foreign substances on the quality and properties of steel, sometimes in one direction, sometimes in another, might easily be multiplied. How to deal with these, or how to remove them, comes clearly within the range of chemical investigation, and entitles the subject of my address to a place among your transactions. So much for the metal when we have obtained it: but it possesses other claims on the attention of the Society of Chemical Industry, viz., in the phenomena which accompany its production.

Many ores of iron as they are delivered to the blast furnace contain 30 or 40 per cent. of earthy ingredients. To these have to be added the ash

contained in the fuel and the lime of the flux, employed for the fusion of the silica and alumina brought in by the other minerals. From this considerable weight of sterile matter pig iron is obtained by means of one of the most successful examples of heat utilisation with which we are acquainted. The crude metal, however, has not run the gauntlet, as it were, unhurt, through substances capable of materially affecting its properties.

To those influences it has been exposed, at an intense temperature, in some cases for 48 hours and upwards, and it is therefore not surprising that some carbon, silicon, sulphur, and phosphorus should be found as constituents of our pig iron. The metal thus contaminated is transferred, still liquid by the heat which has produced it, to the Bessemer converter. In it a very rapid current of highly compressed air oxidises the metalloids, or a greater part of them, with such an evolution of heat that the mass, 99 $\frac{2}{3}$  per cent. of which consists of pure iron, is raised to whiteness of dazzling splendour. By a small addition of carbon and manganese, in about a quarter of an hour from leaving the blast furnace, we may thus have 10 to 15 tons of cast iron changed into steel of great malleability and strength.

These considerations—but there are many others—justify me, I hope, in asking your assent to the proposition of the work of the blast furnace being one of the most interesting and successful applications of chemical science known in industrial enterprise.

This view of my subject was apparently shared by your Council, which, together with the fact of Nottingham occupying a central position of some very important seats of the iron trade, induced them to honour me with a request to prepare an address on a subject to which I had devoted a good deal of attention. Perhaps I may be here permitted to say that their wishes were willingly complied with by myself. The application of scientific investigation to an operation carried on in the manner and on the scale of a huge blast furnace, is beset with many disturbing causes and, in consequence, with many difficulties. For their satisfactory solution lengthened experience and frequent observation are necessary, and I gladly embraced an opportunity of submitting to so competent a tribunal as the members of this Society, my more recent views on the chemical questions involved in smelting the ores of iron.

#### RATIONALE OF THE SMELTING PROCESS.

So far as I am aware the action of the blast furnace continues to be thus described even in the latest work on chemistry.\* “A large number of investigations have been made on the chemical changes which occur in the blast furnace, but in spite of these our knowledge of this subject is still far from complete. The fuel uniting with the oxygen of the blast burns with formation, in the first place, of carbon dioxide, and this is reduced to carbon monoxide by contact with glowing carbon. This latter gas, coming in contact with the constantly descending charges of ore, reduces the ferric oxide to spongy metal. . . . The zone in which this reduction occurs is situated at a higher or lower part of the furnace according to the nature of the ores, and its temperature varies from 600—900° C. As the spongy iron descends it arrives at the hotter parts of the furnace. . . . At this point the finely divided spongy iron begins to take up carbon, and it may

\* “Treatise on Chemistry,” by Sir H. E. Roscoe, F.R.S., and C. Schorlemmer, F.R.S., 1889, Vol. II., p. 53.

therefore be termed the zone of carburisation." The zone in which fusion takes place is then described along with the reduction of certain other metals and metalloids. Allusion is subsequently made\* to experiments of Caillaetet, in which "it appears that even in the hottest parts of the furnace and at the point at which the combustion is most perfect, carbon exists in the solid state from the dissociation of carbon monoxide into carbon dioxide and carbon, brought about at very high temperatures."

My own experiments and investigations have led me to conclude that the action of the blast furnace is somewhat less simple than might be inferred from this description. That the greater portion of the reduction of the ore takes place in the upper zone is doubtless beyond all question. Nothing, however, is said of the important part played by a distance of 30 to 60 feet in the depth of the furnace in intercepting the heat which, but for it, would be wasted. To such an extent is this duty performed, that I have estimated in a modern furnace that for every unit of heat evolved at the tuyeres,  $2\frac{1}{2}$  units are returned to this point from the accumulation in the descending current of materials. It will also be shown that besides the deposition of carbon at high temperatures mentioned by Caillaetet, this action commences with the reduction of the ore, say, at  $150^{\circ}$  C. It will then be shown that if reduction be ever completed in the upper zone, which is more than doubtful, the spongy iron then produced would, during its passage through what I have designated a zone of heat interception, and in presence of an intensely deoxidising atmosphere, be reoxidised by the action causing the deposition of carbon. However this may be, there seem strong reasons for believing that as much as 25 per cent. of the oxygen required to form  $\text{Fe}_2\text{O}_3$  sometimes remains in the ore near the point where complete fusion takes place.

#### ON THE CHANGE EFFECTED BY REDUCTION OF THE ORE ON THE CO GENERATED IN THE BLAST FURNACE.

When carbon monoxide deprives an oxide of iron of all or any part of its oxygen, a corresponding portion is converted into carbon dioxide. Now, as the heat evolved by carbon passing into the state of the latter compound is more than three times as much as when the former oxide is generated (as 8,000 is to 2,400), it is obviously of very great importance that the proportion of carbon dioxide in the gases, as they leave the blast furnace, should be as large as the nature of the operation will permit.

As preliminaries to this inquiry, we have to consider the circumstances which conduce to the formation of carbon dioxide, and those which, when it is formed, tend to preserve its existence.

We do not require to be reminded that carbon dioxide, if produced at the tuyeres, cannot be long continued as such, and the same observation is applicable to the greater part of the height of the furnace. Indeed, experimentally I have proved, and the composition of the gases at its different levels shows, that where the carbon dioxide leaves the limestone, the temperature is such that this gas is resolved, by the incandescent coke, into carbon monoxide. Assuming each 20 parts of pig iron to contain 18.6 of iron, there will be liberated in the reduction of this quantity of the metal 7.97 parts of oxygen, equal to converting 5.97 parts of carbon in the form of carbon monoxide into carbon dioxide. Whatever the exact nature of the changes may be, my

\* Ibid., Vol. II., p. 54.

own experience, and that of all other observers whose work I have examined, have led me to infer that 5.97 cwt. of carbon as carbon dioxide per ton of iron made, is all we can calculate on meeting with in the gases escaping from furnaces engaged in smelting iron ores like those of Cleveland. It is perfectly true that carbon monoxide can be entirely converted into dioxide by contact with oxide of iron, but this happens under conditions, as to temperature, &c. which do not obtain in the case of the blast furnace. Hence we may infer that whenever 5.97 cwt. of carbon as carbon dioxide per ton of iron made is exceeded, it does not represent an *average* amount of the quantity we may expect to find in this form of combination.

#### ON THE QUANTITY OF C AS CO IN THE BLAST FURNACE.

If the correctness of this proposition be conceded, it follows as a necessary consequence that the remainder of the heat must be made up by the combustion of carbon to the condition of carbon monoxide, supposing the air driven into the furnace has the temperature of zero of the centigrade scale. What this quantity of heat may be depends on the nature of the ore under treatment, and the more or less perfect character of the furnace in which the smelting operation is conducted.

For the purpose of making this clear I have constructed two tables. The first table contains a statement of the weights of the various substances used and of those produced in the process, with how much heat, and from it what quantity of coke, has been consumed for each section of the duties it has to discharge. The factors made use of to estimate the quantity of heat are given in an explanatory note affixed to the table itself. In the second table, the quantity of heat evolved by the combustion of the coke in each case is set forth; and here it may be observed that all the calculations are based on the supposition that coke is the fuel employed. It is true, coal is frequently used in its raw or uncoked condition, but this means that the coking operation is effected in the blast furnace, and it is not until the volatile parts have been separated from the remaining portion that the actual work of the furnace begins. A few marginal words are added to table No. II. in respect to the method pursued in the calculations for ascertaining the production of heat. The difference between the two sides of the account, *i.e.*, the excess of heat generated beyond that absorbed, is considered as escaping through the sides of the furnace, by expansion of the blast and trifling errors in the figures themselves.

#### ON THE RELATIONS BETWEEN C AS CO AND C AS CO<sub>2</sub> IN A FURNACE 48 FEET IN HEIGHT WITH A CAPACITY OF 6,000 CUBIC FEET, BLOWN WITH AIR AT ATMOSPHERIC TEMPERATURE.

The work of what is technically known as a cold-blast furnace is set forth under columns A. in the two tables. The production is 90 tons per week with a consumption of 40.76 cwt. of coke, 46.20 cwt. of calcined ironstone, and 18.25 cwt. of limestone. The production of heat is 2,727 calories per unit of coke, and it was made up by each unit of carbon in the gases as CO<sub>2</sub>, being accompanied by 6.12 units as CO. The total quantity of heat so obtained was 111,180 calories, of which no less than 24,148 calories were carried off in the escaping gases, representing 8.85 cwt. or 21.7 per cent. of the heating power of the coke employed.

THE EFFECT OF HEATING THE BLAST TO  $485^{\circ}$  IN A FURNACE OF THE SAME DIMENSIONS AS THAT PRECEDING, VIZ., 6,000 CUBIC FEET.

Neilson, the inventor of the hot blast, was abundantly satisfied on obtaining a temperature of  $330^{\circ}$  C. in the air driven into the furnace. At the Clarence Works and elsewhere,  $485^{\circ}$  was obtained in the cast-iron stoves modified somewhat in construction from those in early use for the purpose. The effect of the change from cold to hot air of this temperature, is set forth in columns B. of the two tables. To secure this a quantity of fuel was burnt in the stoves, representing 35,000 to 40,000 calories, but of this, in the particular instance before us, only 14,488 calories reached the furnace, the remainder being lost by radiation from the stoves and at the chimneys, &c.

Notwithstanding this great escape of heat, 60 to 70 per cent. of the whole, it will be seen that by heating the air, a far greater reduction in the quantity of coke necessary for producing a ton of iron has ensued, than would at first sight have been expected. So much so, that it is a question whether Neilson's want of scientific knowledge on the subject was, at the time, not a matter of congratulation. Had he pursued his inquiries in this direction he would, no doubt, have been landed in the difficulties encountered by able chemists in their attempts to assign a cause for the great saving of fuel, and in consequence might have abandoned any practical work in connection with his valuable invention. Certain it is that the men of science, for nearly 40 years after its application, adopted a somewhat dangerous line of conduct in their attempts to explain the action of the hot blast by greatly over-estimating the actual saving it had effected. Dr. Percy, writing in 1864, quoted, and no doubt quoted truly, that after heating the air to  $300^{\circ}$  F. ( $149^{\circ}$  C.) the total consumption of coal per ton of iron at the Clyde Iron Works was reduced from  $161\frac{1}{4}$  cwt. to  $103\frac{1}{4}$  cwt. In this no doubt was included the great and needless waste in coking the coal, and many other matters having no connexion whatever with the actual work performed within the furnace itself. In reality therefore, the saving at Clyde did not much exceed one ton of coal, but this, or adopting  $12\frac{1}{4}$  cwt. of coke as given in the case before us, obtained by burning 4 or 5 cwt. of coal outside the furnace in the hot air stoves, affords sufficient ground for speculation and inquiry. I hope, however, to be able to convince this meeting that there is nothing mysterious in this apparent anomaly.

The first thing which strikes us on examining the figures is the large increase of heat rendered by a unit of coke, viz., 3,660 calories instead of 2,727, when cold blast was used, or an increase of 34 per cent. This difference is made up as follows: by a small accidental superiority in the coke; by a larger quantity of carbon raised to dioxide; and by the heat contained in the blast.

It will be readily understood that the vast volume of gases, largely expanded by the high temperature of the furnace, may arrive at the point of escape before they have parted with all the heat they are capable of communicating to the solid materials. In other words, there is an unnecessary waste of heat from this cause. When we come to examine the sources of heat in the hot-blast furnace it will be perceived that there is an increase of 409 calories, due to a larger quantity of carbon converted into carbon dioxide than in the cold-blast furnace. Any deficiency in this respect, when using cold air, may be due either to the velocity of the gaseous current not affording time for the conversion of the full quantity of carbon into dioxide, or from the

temperature of the upper region of the furnace being such, that carbon dioxide if formed, is reduced to the monoxide by incandescent coke. It is also possible, indeed probable, that the deficiency of carbon dioxide may be the result of a combination of these two reactions. Besides the improvement in the hot-blast furnace from a higher state of oxidation of the carbon there is an increase of 481 calories contained in the air. These amount together to 890 calories obtained without any addition to the volume of the gases. The effect of this change is that the quantity of gas for a given quantity of pig iron is about 40 per cent. larger in the cold- than in the hot-blast furnace. This diminution of volume will, however, not suffice for the object I have in view, because the hot-blast furnace produces 220 tons of metal while the other is only turning out 90 tons. The net result, therefore, is that in a given time, which means velocity, 75 per cent. more gas is passing through the hot-blast than through the cold-blast furnace.

It will probably occur to some that if there be any loss of heat from this increased velocity of the current of gas, the remedy would be to reduce the speed of the work performed, by regulating the admission of blast. Experience has taught the contrary, and it is conceived for the following reason. If we have a current of heated gas meeting and passing through one of cold solids, there is certain speed which affords the best results in heating the latter and cooling the former. Imagine a tall vessel filled with fragments of metal or stone, and, for ease of motion, we will suppose them to be spherical and of the size of playing marbles. Into the lower end of this vessel a current of hot air is introduced and, after a time, 20 of the marbles per minute are withdrawn, and are found to be very hot. In spite of this, the number is not sufficient to rob the air of all its heat, and in consequence we have the escaping air passing off from the top at a high temperature. To avoid this loss we commence to remove 200 of the marbles per minute, by which the loss of heat in the gases above is effectually checked, but the temperature of the solid spheres is insufficient for the purpose for which they are required. It is clear from this that there is a rate of speed expressed by something between 20 and 200, which, everything considered, is what has to be aimed at. This in the cold-blast furnace is achieved when 90 tons of iron per week are being run, say 15 tons per 1,000 ft. of furnace capacity, and in one driven with hot air a speed represented by 220 tons per week, or 37 tons per 1,000 cub. ft. per week, both making Cleveland iron, is the most successful. It is worthy of note also that the hotter the blast is the quicker the furnace can be driven, and the cooler are the escaping gases.

The saving of fuel in smelting iron ore with hot air is due to two causes. Each unit of fuel has, as we have seen at furnace B, its calorific power raised from 2,727 calories in the cold-blast to 3,660 calories in the hot-blast furnace, while the total quantity of heat required has fallen from 111,180 calories in A to 104,336 calories in B. Let us examine how this last difference of 6,844 calories has been brought about, and for this purpose our attention must be applied to the "Appropriation" of the heat produced in the manner already described. The appropriation referred to is given in two divisions, "Constants" and "Variables," so called because the former, for a given quality of iron in respect to the metalloids it contains, is supposed to call for the same quantity of heat; the latter varies with changes in the quantity of coke and limestone used, and with the percentage of earthy matters in the ore.

To the quantity of heat required for each item in the appropriation account is added its equivalent of coke, and although the actual number of calories

to satisfy the constants remain unaltered, their representation in coke is necessarily changed by the improved efficiency of the latter. In this way an economy by the hot blast of 3.687 cwt. of coke per ton of iron has been effected upon 45,322 calories engaged. In the variables 59,014 calories were absorbed, and approximately it will be found that of the saving of 8.581 cwt. of coke under this head, 5.161 cwt. may be set down to the enhanced power of the coke, and the remaining 3.52 cwt. to the diminished amount of work to be performed. As regards the cause of this diminution, using less coke gives less water to be evaporated, and less atmospheric moisture to be decomposed. A reduced quantity of coke ash lessens the limestone for fluxing, which in its turn needs less heat for the expulsion and dissociation of its carbon dioxide, along with a smaller weight of slag to be melted. Economy in fuel and in limestone tells greatly on the volume of escaping gases, thus effecting a saving of 5.924 cwt. of coke, in furnace B, under this item alone.

#### ON THE ADVANTAGES DERIVED FROM INCREASING THE HEIGHT OF THE BLAST FURNACE.

With the knowledge afforded by the previous examination of the action of the hot blast, it may be said that heating the air is equivalent to an increase in the dimensions of the furnace, *i.e.*, not only is there a great economy in the consumption of coke, but, as we have seen, 1,000 ft. of furnace space affords 37 tons of iron per week instead of 15 tons, as was the case when cold air was used. The natural sequence of this admission would be the probability of some advantage being derived from an enlargement of the furnace as it existed 28 years ago. This brings us back to the time when John Vaughan built a furnace 71 ft. in height, not however from any inference he drew from the reasoning just adduced, because his mind in reference to the chemical action of the blast furnace was very similar to that of Neilson when he proposed heating the blast. Vaughan's idea was to increase the make of the furnace, and in this practical view of the question this very practical man was not disappointed; but his enlarged furnace did more than this, it saved a notable quantity of coke, something like 4 cwt. per ton of iron, if my memory is correct. This height was increased at the Clarence Works and elsewhere to 80 ft. with a cubic capacity varying from 12,000 to 25,500 cub. ft. This advantage, however, has only been obtained by a sacrifice in the output, because in smelting Cleveland stone the production does not exceed 22 tons per 1,000 cubic ft. of capacity, using air heated to 485°. This is precisely the same temperature the blast had in the 48 ft. furnace, and by referring to the figures contained in column C. in the two tables the effect of the additional furnace space will be readily appreciated. The limestone consumed and the weight of escaping gases are considerably reduced, while the efficiency of the coke is considerably increased by the larger quantity of carbon as dioxide per ton of iron. The consequence of this is that a unit of coke now represents 4,053 calories instead of 3,660, as happened in the smaller furnace. This shows an improvement of about 11 per cent., while the requirements have, for the reasons given above, fallen from 104,336 to 91,194, equal to 13 per cent. The net result is that, instead of 28.5 cwt. of coke being burnt per ton of iron, the quantity fell to 22.5 cwt.

In confirmation of what has been advanced respecting the similarity of effect in heating the blast or increasing the dimensions of the furnace, there is placed in adjoining columns the results obtained in the cases A and B in

the tables. To these are added the particulars of a much loftier furnace than that given under B, but, like A, blown with cold air:—

	A.	B.	—
Height in feet .....	48	48	70
Cubic capacity .....	6,000	6,000	7,500
Blast .....	Cold	485°	Cold
Calined ironstone used per ton of iron ..... Cwt.	46·20	48·00	50·00
Limestone used per ton of iron ..... ..	18·25	16·00	13·00
Coke used per ton of iron ..... ..	40·76	28·50	32·00
Weekly make per 1,000 cubic feet of furnace capacity ... Tons	15·0	36·7	19·3

Thus, by a mere alteration in dimensions, a saving has been obtained of 8·76 cwt. of coke per ton of iron, and the produce per 1,000 cubic feet of capacity approximates to that obtained from a modern Cleveland furnace. In all probability, had the height been increased to 80 feet, the consumption of coke would have been as favourable as that given under column B.

After what has been said in explanation of the items of saving realised under columns B., it cannot be necessary to explain in detail the advantages due to the enlargement of the furnace C as compared with B. These will be readily understood by a comparison of the figures in the tables.

The benefit derived from the addition of 32 ft. to the height of a furnace 48 ft. high having been settled beyond all questioning, an ironmaster, who had built four 80 ft. furnaces, named to me his intention of erecting a pair 100 ft. high. This led me to reflect on the nature of the action in the upper zone. A reference to the figures under column C. will indicate that of the total heat (79,656 calories) generated by the combustion of the carbon 33,432 calories, or 42 per cent., are due to the burning of C as CO to CO<sub>2</sub>. It has further to be remarked that this oxidation, or combustion, begins almost immediately on the introduction of the ore, and is completed, as far as it can be, in the first 15 ft. from the upper surface of the materials in an 80 ft. furnace. Practically, however, it may be said, very little of this heat will manifest itself in the sensible form in the gases, because a large proportion of it (the greater part of the 33,108 calories) is absorbed in tearing away the oxygen from the iron in the ore. I proved experimentally, however, that by arresting the office of reduction in the upper zone there was a marked decline in the temperature of the gases. This was done by withdrawing the ore from the charges and substituting a mixture of slag and flints in its room. In a short time the temperature of the escaping gases began to fall, and when this was stationary the new mixture was discontinued and the ore resumed. In due course the gases became hotter, and speedily regained their normal temperature. The difference was estimated at 220° C., and taking the gases at 137 cwt. per ton of iron, this would represent 7,138 calories, or nearly 8 per cent. of the entire heat generated in such a case as the example given under column C.

The inference I drew from this experiment was that any addition to the height of a furnace after a certain altitude would prove useless, and of this I

warned the owner, who, however, disregarded my advice. He built his two furnaces 103½ ft. high, and to my surprise reported he was making a ton of iron with 18 cwt. of coke. This was a saving of about 4 cwt., which was 30 per cent. more than the entire loss of heat in the waste gases in an 80 ft. furnace, working in the manner set forth in column C.

My friend, acting in perfect good faith, willingly allowed me to examine the condition of these two monster furnaces, and to compare them with other furnaces at his works 80 ft. in height, and using the same minerals. The following were the results of this examination:—

The temperature of the escaping gases between the two types of furnace only differed by 7° C.

The quantity of carbon in the gases, as judged by its relation to the nitrogen present, was precisely the same in both.

Samples of the gases were taken over 2½ to 3 hours. In the 80 ft. furnace the carbon as CO<sub>2</sub> was as 1 to 2·87 as CO, and in the 103½ ft. furnace it was as 1 to 2·86.

From this I concluded that it was a mistake to imagine that there was any such difference in the consumption of coke as had been supposed, an opinion which was confirmed by subsequent events. It is perhaps only right to observe that the loftier furnaces were being driven below the speed I should have thought best adapted for economy of coke, that is, instead of running 22 tons per week per 1,000 cub. ft. of capacity, they were only giving 18 tons.

We may therefore infer, that raising a furnace beyond a certain height, such height varying according as the iron oxide parts more or less easily with its oxygen, is useless. The reason is that the zone of reduction, and therefore of heat generation, has its position raised with each needless increase in the altitude of the structure, whereby the temperature of the gases remains unchanged, and the loss from this cause continues unaltered.

Before leaving the question of capacity of furnace I would say that, while there may be some advantages connected with colossal furnaces, I greatly doubt whether economy of fuel can be justly reckoned among them. In my opinion a height of 80 ft., and a capacity of 16,000 cub. ft., suffice for all we can expect in this direction, when smelting the ore of Cleveland.

#### ON RECENT INCREASES IN THE TEMPERATURE OF THE BLAST.

When it was ascertained at the Clarence Works that air at a temperature of 535° C. had enabled us to produce a ton of iron in our 48 furnaces with about 25 cwt. of coke, experiments were set on foot to introduce the regenerative system, as it had been named by Siemens, for heating the blast. This was done in the hope that an amount of heat could be introduced into the furnace beyond the power of iron pipes to supply it. Mr. E. A. Cowper, largely assisted by Mr. Charles Cochrane had, I afterwards learnt, made considerable progress in the same direction previous to my trials, and to these gentlemen we are indebted for the successful introduction of what is now well known as the "brick stoves."

Impressed as I had been and still was with the desirability of an alteration in the construction of the hot blast stoves, I never could see my way to adopt the opinions entertained by some of my colleagues in the trade, as to what was capable of accomplishment by this new form of apparatus. From 13 to 16 cwt. of coke of average Durham quality was not infrequently spoken

ot as sufficing to produce a ton of Cleveland iron, my own expectations being limited to about 20 cwt.

The facts and figures which have been set forth in these pages render it easy to judge of the difficulties in reducing the coke consumed below a certain point. For the purpose of illustrating this I have followed the same mode of calculation as that adopted in the tables, on the supposition that 18 cwt. per ton of metal was the weight consumed. With the reduction in the quantity of coke, 9 cwt. of limestone instead of  $10\frac{1}{2}$  and 11 cwt. have been assumed as the quantity to be used. It is not necessary that more should be done than remind the members of the changes consequent upon using a smaller quantity of coke and flux. What does concern us is, that the 18 cwt. of coke producing the theoretical quantity of  $5.97$  cwt. of carbon in the form of dioxide, and the remainder as monoxide, will give 1 of C as  $\text{CO}_2$  to  $1.81$  as  $\text{CO}$ , in respect to the possibility of which some doubt may be entertained in smelting Cleveland ore. One thing, however, is certain, the blast would be considerably lower in quantity than anything hitherto reached in Cleveland under similar circumstances. The weight would be only  $77.97$  cwt. per ton of metal, and to supply the complement of heat required, 16,900 calories would be needed in the blast, equal, therefore, to a temperature of  $914^\circ \text{C}$ . This, I take it, would be extremely difficult with the present hot-air apparatus, even of brick, to secure. To show how rapidly this obstacle increases with each diminution in the coke, I have estimated that for 16 cwt. of coke to the ton of iron, which has been named as possible, the blast would weigh only  $67.72$  cwt., and that then a temperature of  $1,605^\circ \text{C}$ . in it would have to be secured.

#### ECONOMY OF FUEL IN FURNACES OF MOST MODERN CONSTRUCTION.

We may now abandon mere speculation as to what may be done in further economy of fuel in smelting ore of the Cleveland character, and confine ourselves to what has been accomplished. Column D. affords such an example when in a furnace 90 ft. in height, and a capacity of 33,488 cub. ft., a ton of iron was said to have been produced with  $19.69$  cwt. of coke. It may further be remarked that the analysis of the gases, made by the Clarence chemist Mr. Rochall, confirmed this statement. The temperature of the blast was ascertained to be  $710^\circ$ , but it does not appear, for a complete understanding of the workings of this furnace, more need be said than a reference to the particulars as they are to be found in the two columns D. in Tables I. and II.

The column E. is one of the Clarence furnaces, 80 ft., with a capacity just about half that of D., 15,500 cub. ft. The coke consumed is a little higher than under D. ( $.30$  cwt.), but it has to be observed that when working with such high loads of mineral upon the coke, we may expect some trifling fluctuations in respect to the fuel consumed. Still, I am not prepared positively to deny that the extra dimensions of D. may, at such high blast temperatures, have a trifling advantage. At the same time, this is doubtful.

#### QUANTITY OF FUEL REQUIRED IN CONNECTION WITH THE USE OF LIMESTONE OR LIME.

In directing our attention to the manner in which the heat in the blast furnace is disposed of, we cannot fail to be struck with the share rendered

necessary by the presence of the carbon dioxide liberated from the limestone. This is particularly evident in the old type of furnace as set forth in columns A. and B. of the tables. There is the loss of carbon of the coke due to the action upon it of the carbon dioxide set free, and also the heat required to expel and decompose this gas.

The sum of the items connected with the use of limestone amounts in the cold blast furnace A. to 5·046 cwt. of coke, and in B., blown with hot air, to 3·29 cwt. This is exclusive of a loss of carbon carried off by the liberated dioxide from the flux. It is to be feared that in olden time we did not realise the full extent of the evil, but knowing generally that heat was necessary to drive off the CO<sub>2</sub> in a limekiln, it was assumed that a saving might be effected by previous calcination of the flux, without much or indeed any calculation what that saving might amount to. It happened in the old type of furnace—say, 48 ft. in height—that the heat carried off in the gases represented 4·99 cwt. of coke in the hot-blast furnace and 8·85 cwt. in that blown with cold air. There was, therefore, heat enough and to spare with such a loss at the throat to effect at all events some economy. In a paper read before the Iron and Steel Institute in 1875, I showed that the saving was under 1½ cwt. of coke, and it was then proved that a portion of the difference between practice and theory, *i.e.*, imperfect theory, arose from the imperfect mode of burning the lime, by which a considerable portion of the carbon dioxide was still left in the flux. We shall see when we come to consider the action of a furnace using well calcined lime to what this difference between calculation and experience was owing. Still 1½ cwt. of coke was worth something, at the same time it must be remembered that this saving was only effected by burning probably double this weight of coal in the limekiln, probably nearer 4 cwt. than 3. But paying 3s. or 4s for small coal and 10s for coke left a margin, and therefore the plan was not infrequently adopted. When the large furnaces came into use it was perhaps to be expected, if for no other use than for information's sake, that burnt lime should be tried in them. At the same time, as the heat carried away in the gases was only about half its former quantity, there was no longer the margin out of which the additional work could be performed, *i.e.*, instead of the heating power of 4·99 cwt. of coke being in the escaping gases as happened in a 48 ft. furnace blown with air at 485° C., there was only that of 2·49 cwt. in the gases of an 80 ft. furnace with blast at the same temperature. The trials at the Clarence Works, of which full particulars were published at the time, gave such results as led to their abandonment by my firm, which was followed by my late friend Edward William, who confirmed the conclusions laid down in the discussion which followed the reading of the paper on the subject.

A dozen years afterwards the use of caustic lime again found favour in Cleveland, but it speedily disappeared. This was admitted by its former advocates upon a recent occasion, when entire success attending its application was alleged to have been achieved at a Middlesbrough furnace. I will shortly give the reasons for my believing that the results then communicated were not conclusive of any economy having been realised in this new trial.

The experiment was made in a furnace 76 ft. high, with a capacity of 20,454 cub. ft. When working upon raw limestone, it was alleged to have consumed 23·28 cwt. of coke per ton of metal, and on lime, 19·49 cwt., the saving thus stated being 3·79 cwt. The comparison involves, in my judgment, a fallacy at the outset, for such a furnace, using limestone, ought, with its blast heated to 765°, to have produced a ton of iron with less than 21½ cwt. of coke. The saving then, in reality, was less than 2 cwt., instead

of 3·79 cwt. So far back as 1875, I not only showed that in 80 ft. furnaces there was no economy in using caustic lime, but the reasons of its failure in this respect were described.

Caustic lime, as is well known, on exposure at ordinary temperatures, attracts  $\text{CO}_2$  from the mere trace contained in the atmosphere. Of course, this absorption is much more rapid in gases containing, like those escaping from a blast furnace, about 12 per cent. of their volume of this gas, and the rate of absorption is further greatly accelerated at higher temperatures, but short of what is required to convert limestone into lime. What takes place then in the upper region of the blast furnace, when caustic lime is used, is a re-absorption by the lime of the carbon dioxide produced by the reduction of the ore. The calcium carbonate thus formed, on reaching the hotter zones of the furnace, loses its  $\text{CO}_2$ , and an action is set up precisely the same as if limestone had been used, so far as the dissociation of carbon dioxide is concerned. The figures given in the paper descriptive of these fresh trials, however, indicate the decomposition of a larger quantity of this higher oxide of carbon than when limestone in its native condition is employed. This, in all probability, is increased by an undoubted generation of heat produced in the reducing zone by the union of carbon dioxide with the lime. However this may be, there is the fact of the particular furnace in which the trial was made containing per ton of iron only 4·33 cwt. of carbon as dioxide in the gases, instead of a quantity approaching 6 cwt. A consequence of this disturbance, in spite of a very high temperature of blast, is a great falling off in calorific power of the coke. I give the results of columns E. and F. to illustrate the nature of this decline of power:—

Sources of Heat per Unit of Coke.	E. Clarence Furnace of 80 ft., 15,500 cub. ft., Blast 704, using 19·39 Cwt. of Coke per Ton of Iron.	F. Furnace, 70 ft. High, 20,451 cub. ft., Blast 765, and using 19·49 Cwt. of Coke per Ton of Iron.
Conversion of C into CO .....	2,032	2,120
Conversion of portion of this C as CO into $\text{CO}_2$ .....	1,672	1,244
Heat in blast for each unit coke.....°.....	727	738
	4,431	4,102
Weight of C as CO to each unit of C as $\text{CO}_2$ in the gases .....	} 2·18	2·94

It happens that the Cleveland stone contains usually such a quantity of lime that something like 3 cwt. of this earth, from this cause, finds its way into the furnace for each ton of iron produced. It appears, however, that the lime is in such a state of combination as not to be affected by  $\text{CO}_2$ . This was proved experimentally when a mere trace of the carbon dioxide was absorbed by the calcined ore.

#### GENERAL CONCLUSIONS.

In answer to those who, in order to effect further economy in the consumption of coke in the blast furnace, recommend the use of furnaces of

great height and large dimensions, who advocate the use of caustic lime, and insist on imparting unmanageable heat to the blast, I would beg attention to the lessons taught by the example given under column E. There, a furnace of 15,500 cub. ft. capacity, blown with air at a comparatively moderate temperature, and using raw limestone, compares favourably with furnaces twice its size with a much hotter blast and deriving such advantages as calcined limestone is regarded as being capable of affording.

I am very far from undervaluing the very great importance of the lessons taught by the various trials made with the view of reducing the cost of producing pig iron. There is no doubt the iron trade is under very great obligations to those who, at considerable expense and trouble to themselves, have given us the benefit of their experience, without which almost all speculation is useless.

#### EXPERIMENTAL WORK, AND INFERENCES DRAWN THEREFROM.

When the feasibility of heating the air to  $750^{\circ}$  had been demonstrated, and the great expectations as to its future influence on the iron trade was dwelt upon, I ventured to urge the difficulty just referred to: the difficulty being a rapidly-increasing temperature in the blast chiefly arising from a reduced volume of air having to carry a larger quantity of heat. There were, however, other questions, but of a purely chemical character, which it seemed to me might impose a limit to the economy expected from the use of a more intensely heated blast than had hitherto been in use. This limit I conceived might be established from the known oxidising power of carbon dioxide on metallic iron, particularly when the latter is in the spongy state. This evidently, under certain conditions as to temperature, could not fail to weaken if not to arrest the reducing power of the carbon monoxide. There was also the faculty possessed by heated carbon to decompose the dioxide generated by the reduction of the oxide of iron. The full force of this reflex action is easy to perceive when it is remembered that for every unit of carbon so treated the heat of  $2.33$  units in the form of monoxide is required to take its place.

I propose now to give a brief abstract of some experiments upon which the conclusions set forth in these pages have been founded.

It was ascertained that at  $200^{\circ}$  C., the ferric oxide in Cleveland calcined ironstone begins to lose its oxygen, but the action is faint; at  $210^{\circ}$  it became marked, and at  $225^{\circ}$  it was rapid.

The following shows the starting points of the action of reduction on different varieties of oxide:—

—	Lowest Temperature at which $\text{CO}_2$ appeared.	Temperature of Marked Action.
	$^{\circ}$ C.	$^{\circ}$ C.
Pure precipitated $\text{Fe}_2\text{O}_3$ .....	141	149
$\text{Fe}_2\text{O}_3$ obtained by calcining $\text{FeNO}_3$ .....	145	154
Calcined Cleveland ore ( $\text{Fe}_2\text{O}_3$ ) .....	199	210
$\text{Fe}_2\text{O}_3$ obtained by calcining $\text{FeSO}_4$ .....	208	216

The percentage of oxygen lost in seven hours by specimens simultaneously heated in a vessel to about  $417^{\circ}$  C. and exposed to a current of CO :—

	Original Oxygen Removed, Per Cent.
Calcined Cleveland ore.....	9.4
Fe <sub>2</sub> O <sub>3</sub> got from calcined iron sulphate.....	61.7
Fe <sub>2</sub> O <sub>3</sub> precipitate.....	66.7
Fe <sub>2</sub> O <sub>3</sub> from calcined iron nitrate.....	72.7

Exposure, in a similar vessel, to CO at a temperature of  $421^{\circ}$  gave the following results :—

	Percentage of Iron.	Original Oxygen Removed, Per Cent.
Calcined spathose ore.....	51.7	15.4
Elba specular ore.....	66.8	16.8
Lancashire hematite.....	66.6	35.9
Calcined Cleveland ore.....	40.0	37.3
Pure precipitated Fe <sub>2</sub> O <sub>3</sub> .....	70.0	49.2
Fe <sub>2</sub> O <sub>3</sub> from calcined FeSO <sub>4</sub> .....	70.0	60.8

By slowly passing CO over an excess of Cleveland calcined ore, the gas was converted into CO<sub>2</sub>, but of the oxide of iron only 5.25 of its oxygen was removed.

At a temperature of  $300^{\circ}$  pure carbon dioxide was passed over pure spongy iron without change, but at the melting point of zinc ( $417^{\circ}$ ) the action was very rapid. The metal was oxidised and the gas was almost entirely converted into carbon monoxide.

Hard Durham coke, silvery in appearance, is only slowly affected by carbon dioxide at a bright red heat, but at the temperature near the tuyeres of a blast furnace the change may be regarded as instantaneous. On the other hand, soft dull-looking coke is affected by carbon dioxide in the much lower temperature of the reducing zone. The usual proportion of C as CO<sub>2</sub> to C as CO is as 1 to 2.6 in an 80 ft. furnace receiving its blast at  $485^{\circ}$ . Under the same circumstances, but using soft coke, it became as 1 to 2.82.

A mixture of 2 vols. of CO and 1 of CO<sub>2</sub> (1 C as CO<sub>2</sub> to 2 C as CO by weight) and another of 3 vols. of CO to 1 of CO<sub>2</sub>, were passed through a vessel containing the following substances, the temperature being  $417^{\circ}$  C. :—

	LOSS PER CENT. OF ORIGINAL OXYGEN.			
	2 Vols. CO, 1 Vol. CO <sub>2</sub> .	2 Vols. CO, 1 Vol. CO <sub>2</sub> .	3 Vols. CO, 1 Vol. CO <sub>2</sub> .	3 Vols. CO, 1 Vol. CO <sub>2</sub> .
	5½ Hours Exposure.	11½ Hours Exposure.	5 Hours Exposure.	10½ Hours Exposure.
Calcined Cleveland ore .... Loss of O	Per Cent. 0.9	Per Cent. 4.3	Per Cent. 1.9	Per Cent. 29.3
Fe <sub>2</sub> O <sub>3</sub> from pure nitrate ... ..	2.4	16.2	..	..
Precipitated Fe <sub>2</sub> O <sub>3</sub> .....	2.9	14.0	26.6	38.6
Fe <sub>2</sub> O <sub>3</sub> from calcined FeSO <sub>4</sub> . ..	3.4	..	..	..

Recently the following experiments were made. A mixture of 1 vol.  $\text{CO}_2$  and 2 vols. CO were passed for 40 hours over calcined Cleveland ore; the temperature varying from  $400^\circ$ — $480^\circ$ , the average being  $441^\circ$ :—

—	Composition before Exposure.	No. 1 Composition after Exposure.	No. 2 Composition after Exposure.
Iron .....	41.44	43.62	43.20
Oxygen .....	17.71	11.69	13.22
Carbon deposited.....	Nil.	1.70	1.00
Earthy matter.....	40.85	42.99	42.58
	100.00	100.00	100.00

In No. 1 the loss of original oxygen was 33.99 per cent. in 40 hours; and in No. 2, 25.35 per cent. in 15 hours, the temperature in the latter varying from  $430^\circ$  to  $470^\circ$ . In it 2 grms. were exposed to a current of the mixed gases, continued for 5 hours, during which 550 cc. were passed over. This was done three times upon the same specimen of ore, the loss of oxygen being as follows:—

	Grms.
After the first exposure .....	.0338
After the second exposure.....	.0046
After the third exposure .....	.0001
Total loss .....	.0385

A mixture of 36 vols. of  $\text{CO}_2$  and 64 of CO was passed over spongy iron for  $13\frac{1}{2}$  hours, the temperature being one of bright redness. In about six hours the composition of the gas was 31 vols. of  $\text{CO}_2$  and 69 vols of CO (1 of C as  $\text{CO}_2$  to 2.22 of C as CO by weight), after which no further change occurred.

The same experiment was tried at a white heat, the mixture at the commencement being 36 vols. of  $\text{CO}_2$  and 64 of CO. In two hours the composition was 10 of  $\text{CO}_2$  and 90 of CO, or 1 to 9 of C by weight in the two gases.

A large number of experiments of a similar character were performed in the laboratory, all of course tending to show the antagonistic tendencies of the two gaseous oxides of carbon and the conditions which increased or diminished the activity of each. From this I inferred that in actual practice, when smelting Cleveland pig iron in the most perfect furnaces we possess, the neutral point was being approached. This opinion received confirmation from the fact that on exposing Cleveland calcined ironstone as a coarse powder to the action of the escaping gases, with their composition of, say, 1 of C as  $\text{CO}_2$  and 2.20 as CO, and having a temperature of about  $400^\circ$ , we were approaching the limit to which carbon monoxide could deprive such an ore of its oxygen. By this is meant that the action should proceed with sufficient rapidity for reduction to be largely effected before the ore passed into a zone of the furnace, where from the elevation of temperature the carbon dioxide generated would resolve into CO ( $\text{CO}_2 + \text{C} = 2 \text{CO}$ ).

When a mixture of equal volumes of CO and  $\text{CO}_2$  was passed at a bright red heat over factitious  $\text{Fe}_2\text{O}_3$ , calcined Cleveland ore, Lancashire hæmatite, calcined spathose ore, and pure spongy iron, all the ferric oxides were reduced to ferrous oxide, at which they remained stationary, while the spongy iron was

oxidised to the extent of becoming also FeO, after which no further change took place.

The following trials were made with the CO<sub>2</sub> in excess, and in which Cleveland calcined ore was exposed under the conditions named. The last specimen was Cleveland ore in which the iron had been completely reduced by H.

CO.	CO <sub>2</sub> .	Temperature.	Loss of original O.	Period of Exposure.
Vol. 1	Vols. 1.25	420° C.	Per Cent. 5.25	Hours. 1 $\frac{3}{4}$
1	2.2	Visibly red.	11.70	1 $\frac{1}{2}$
1	4.0	Full red.	15.70	1 $\frac{1}{2}$
1	6.0	Low red.	5.80	$\frac{1}{2}$
1	6.0	Red heat.	6.00	$\frac{1}{2}$
1	6.0	Bright red.	87.00 of O = in Fe <sub>2</sub> O <sub>3</sub> , absorbed.	$\frac{3}{4}$

At a temperature of 417° C., CO<sub>2</sub> oxidises spongy iron, but in a mixture of equal vols. of CO and CO<sub>2</sub> this action is entirely arrested. At a red heat, however, the metal was rapidly oxidised.

From what has preceded it may be inferred that a position of stable equilibrium exists in which the oxide of iron ceases to lose oxygen, and the mixture of the two gases remains unchanged, the point of stability being affected by the temperature.

When trials were made at the blast furnace, the following information was obtained in experimenting with a furnace having a capacity of 25,500 cub. ft. The average temperature of the escaping gases was 312°. The quantity of CO<sub>2</sub> varied from 34 vols. to 45 vols. per 100 of CO, the average of 13 trials being about 37  $\frac{1}{2}$ . The following figures show the percentage of original oxygen removed:—

In 1 Hour.	In 2 Hours.	In 24 Hours.	In 48 Hours.
5.31	6.19	3.72	5.71

#### CHEMISTRY OF THE REDUCTION OF OXIDE OF IRON IN THE BLAST FURNACE.

It is now time that we should pass on to the concluding remarks I have to offer in reference to the action of the blast furnace. Reference was made in my opening remarks to the fact of this not being as simple in its character as has been supposed. Had the old views of the reduction of peroxide of iron to the state of metal been correct it would have been expressed by the following equations:—We must suppose Fe<sub>2</sub>O<sub>3</sub> by the action of CO brought down to a state of oxidation expressed by Fe<sub>x</sub>O<sub>y+1</sub>, when it encounters a fresh portion of CO, which will be designated in quantity as *y* CO. We have thus—

and then

Of course, for reasons already stated, there is and must be an excess of CO present, it being considered impossible to convert all the CO into CO<sub>2</sub>. In or near the hearth, as formerly mentioned, the atmospheric moisture, silicon, phosphoric, and sulphuric acids part with their oxygen, the metal absorbing their bases along with a portion of carbon to form pig iron.

It had been observed by Ebelmen and others, and largely commented on by Percy, that there appeared an excess of oxygen at the tuyeres, *i.e.*, there was more than the quantity corresponding with the nitrogen and moisture of the atmospheric air which entered at the tuyeres. This observation has since been confirmed by my own observations and those of others. So far, however, as I have been able to discover, an accompanying increase of carbon in the gases had altogether escaped notice. Without any knowledge of what had been done by Schinz and others in connexion with the splitting up, in presence of iron and its oxides, of carbon monoxide into carbon and carbon dioxide, I became aware of the fact that in exposing iron ore to the escaping gases of a blast furnace, there was a copious deposition of a black substance which became as it were infiltrated in the ore, and which was found to be carbon. This discovery was followed up at a very great length of laboratory examination of the phenomena connected with this reaction, and in this I had the assistance of Dr. C. R. Alder Wright. These have been described elsewhere.\* I shall in consequence content myself with a simple enumeration of the reactions themselves of CO<sub>2</sub> and CO on metallic iron and its oxides:—

#### ACTION OF CO<sub>2</sub> ON SPONGY IRON.

This is the converse of that set forth in the previous equations, the metal being reoxidised with the reduction of the CO<sub>2</sub> to CO. The two equations are thus expressed:—

and then

#### ACTION OF CO ON SPONGY IRON OR PARTIALLY REDUCED OXIDE OF IRON.

When the metal in the conditions named, is exposed to a current of CO at certain temperatures, pure C is precipitated with absorption of some O by the metal or its sub-oxide:—

or

At other temperatures the additional oxygen thus taken up is removed and, as regards the carbon monoxide, the equations *a* and *b* express the change, *viz.*:—

It may also happen that at higher temperatures the liberated carbon may completely reduce the iron oxide as follows:—

At last, when the heat is raised, the carbon liberated may be dissolved by CO<sub>2</sub> formed in some of the previous reactions, and we get:—

\* Chemical Phenomena of Iron Smelting and Principles of the Manufacture of Iron and Steel.

It seems highly probable that the changes set forth in the preceding equations afford an explanation to the phenomena which excited so much surprise in the mind of my late friend Dr. Percy. The two following sets of analyses exhibit the composition of the gases of an 80 ft. furnace taken at different levels. The observations contained in No. 1 were made when raw limestone was being used, whereas in No. 2 the flux had been previously calcined; hence the difference in the quantities of O and C throughout. The figures given express cwt. per ton of iron produced:—

—	Temperature.	Oxygen, No. 1 Carbon.		Oxygen, No. 2 Carbon.	
Escape pipe .....	250° C.	33·40	20·96	29·00	20·28
Depth below surface of minerals 8½ feet	450° C.	26·18	18·52	25·00	17·23
„ „ 18 „	780°	24·12	18·14	24·70	17·32
„ „ 31 „	Bright red.	26·24	18·36	24·65	17·42
„ „ 41½ „	Very bright red, gradually increasing to white heat.	25·26	18·92	24·72	18·08
„ „ 57 „		25·16	18·62	24·14	17·98
„ „ 62½ „		25·01	18·78	24·74	17·80
Four feet above floor of hearth 68 „		27·56	20·26	26·96	19·34

After making allowance for the oxygen separated from the metalloids and atmospheric moisture, there remains about 2·04 cwt. of this gas for every ton of iron made. At the same time there is an increase between the same points (62½ ft. level and 68 ft. level) of about 1·65 cwt. of carbon.

Other examples gave per ton of iron:—

Increase at tuyeres of O cwt.....	1·45 — 1·81 — 2·22
„ „ C „ .....	1·55 — 2·68 — 1·91

The differences in oxygen were thus estimated:—

Quantity actually found in gases in first case given.....	Cwt. 27·56
Less corresponding to nitrogen present .....	22·65
Present in $P_2O_5$ ·39— $SO_3$ ·55— $SiO_2$ ·55 reduced ....	1·49
Separated from lime to form CaS in slag.....	·72
From moisture in blast.....	·66
	25·52
	<u>2·04</u>

As regards Cailletet's experiment quoted by Roscoe and Schorlemmer, from which the production of solid carbon in the hottest part of the furnace is inferred, this phenomenon was ascribed by the first named chemist, and confirmed by St. Claire Deville, as being due to the dissociation of carbon monoxide by the intense temperature in the crucible.

One of the analyses cited by Cailletet in support of this view will be made use of for the purpose of examination. The sample of gas was gathered from a furnace in which charcoal was used, and consisted, by weight, of:—

Free Oxygen.	Hydrogen.	Carbon Monoxide.	Carbon Dioxide.	Nitrogen.
17·03	0·12	2·08	4·61	76·16 = 100

The total oxygen, free and combined, almost exactly corresponds with the nitrogen, as the two gases exist in atmospheric air. Of carbon in the gaseous condition, there was only about one-tenth of the usual quantity found in the gases taken from the crucible of a blast furnace. Such carbon as Cailletet collected, lined the pipe used for withdrawing the gases for analysis. If the explanation of the French chemists be correct, the entire specimen of the gas, of which the composition is given above, must have had nine-tenths of its carbon precipitated from the carbon oxides, while being maintained at the necessary temperature by the combustion of the adjacent fuel. This is inferred from the fact that, in the specimen itself, the unburning, as it were, of 90 per cent. of the carbon it contained must have been accompanied by a great cooling of the gases immediately concerned in the change. There are, it seems to me, obvious difficulties in accepting this as a condition of things likely to occur in the hearth of any blast furnace.

Now I have observed when a furnace is blown out, that there is, not only in the zone of greatest heat, but far above it and in a comparatively cool position, a copious deposit of fine carbon. This I have hitherto ascribed to the dissociation of monoxide by iron or its suboxides, in the manner already mentioned. May not that noticed by Cailletet have been liberated from the ore under the circumstances just mentioned? permeated, as we know it becomes, with carbon. This separation I am supposing may take place as the reduced ore fuses at or near the tuyeres, and that the free oxygen in reality was obtained from a point, where the blast had not had time to combine with more carbon than that represented by the small quantity, mentioned in Cailletet's researches in the form of CO and CO<sub>2</sub>.

This dissent from the opinions of such distinguished chemists is expressed with much hesitation, but I venture to submit it as an alternative explanation which perhaps merits notice.

For reasons already adduced, the presence of carbon dioxide in the gases from a blast furnace constitutes an important feature in its action. Having regard to the thermal conditions of its interior, I see no grounds for hoping that the quantity 5.97 cwt. per ton of iron can be materially increased. This figure, however, is liable to fluctuation with differences in the composition of the pig iron, it being based on metal containing 93 per cent. of Fe. Percy mentions one of 96.274 per cent., for which the equivalent of C as CO<sub>2</sub> would be 6.18 instead of 5.97.

It may be useful to consider the obstacles to an increase of CO<sub>2</sub> beyond the points just named. It is possible, chemically speaking, to completely convert CO into CO<sub>2</sub> in reducing iron oxide, but practically in a blast furnace I regard it as impossible. Experimentally it has been proved, in the case of Cleveland ore, how slow the operation is when the reducing power of 2 vols. of CO is opposed by 1 vol. of CO<sub>2</sub> at temperatures below 480° C. An increase in the CO<sub>2</sub> would augment this inconvenience, and in that way the reduction of the ore might be delayed, until the mineral arrived at a level in the furnace where the heat would resolve any CO<sub>2</sub> which was formed into CO.

Let us, however, imagine an increase in the proportion of CO<sub>2</sub> to be practicable under circumstances where the work in the crucible permitted it. Suppose the coke to be reduced in quantity, and the deficiency in heat to be made up by an increase in CO<sub>2</sub>, generated in the reducing zone. The position of this zone is such that much of the heat generated therein would be carried off in the escaping gases. But, for the fusion of the slag and iron, &c., a certain amount of heat is required in the hearth, which has to be supplied by a given quantity of coke burnt with heated air. Diminish

this and disaster is sure to follow. It happens, however, that there are to be found ores so constituted that the work in the hearth is very much less than with a mineral resembling that of Cleveland and others. In the two tables an example is given under columns H., of the truth of this statement. In it grey forge iron is made in a very small furnace receiving its blast at only 200°, with 15·44 cwt. of fuel. It is true this fuel is charcoal, but I know from personal inquiry on Lake Superior, in Sweden, and in Carinthia that for like work, this form of fuel is not more effective than coke. The advantage of the position will be seen at once to be due to the diminished amount of duty involved in producing the ton of iron. This is apparent enough when we see that, instead of 80,000 to 85,000 calories being absorbed as in smelting Cleveland ore, 61,208 calories have sufficed for the Swedish furnace given under columns H. in the two tables.

Through the kindness of my friend Professor Åkerman, of Stockholm, I have the particulars of 27 Swedish furnaces, all using charcoal. Of these, 11 show a larger proportion of C as CO<sub>2</sub> than I have ever met with in Great Britain, where the proportion 50 vols. of CO<sub>2</sub> to 100 vols. of CO is, I suspect, never reached. Below, the actual vols. of CO<sub>2</sub> per 100 vols. of CO are given, and in some cases, along with the cwt. of C as CO<sub>2</sub> the weight of charcoal per ton of pig consumed, &c. are inserted:—

Vols. CO <sub>2</sub> per 100 vols. CO.	50·4	56·2	56·3	58·4	60·4	60·9	61·2	68·3	69·1	75·10	85·3
Cwt. C as CO <sub>2</sub> per ton pig.	4·24	4·99					4·89			5·47	5·83
„ charcoal „ „	19·36	19·02	18·2	19·60	20·4	17·01	17·26	15·70	15·66	17·50	15·44
„ ore „ „	36·36	41·40					39·71			39·13	36·44
„ limestone „ „	3·24	2·60					5·09			5·47	4·36
„ slag produced „ „	12·26	16·02					15·56			15·15	12·01
1 of C as CO <sub>2</sub> to 1 C as CO.	1·98	1·78	1·77	1·71	1·65	1·65	1·63	1·46		1·33	1·17
Temp. of blast C .....	200°	300°	200°	200°	170°	300°	200°	100°		230°	200°
„ gases C .....	400°	145°					182°			225°	222°
Height of furnace ... feet	54½	53½					48¾			50½	42
Weekly make per 1000 c. ft.											
of furnace capacity . tons.	40·7	41·3					47			41·6	41·1

The large production per 1,000 cubic feet of furnace space, twice that of the Cleveland furnaces, may be taken as chiefly due to the readiness with which these Swedish ores part with their oxygen.

In none of these, it will be seen, does the C as CO<sub>2</sub> in the gases amount to what is commonly found in the furnaces of our own country, reckoned upon the ton of iron made.

#### CYANOGEN IN THE BLAST FURNACE.

There is one chemical reaction in the blast furnace which merits some notice, viz., the generation of cyanogen. This is not from any importance the subject as yet possesses as a commercial question, because the quantity so produced is not large, and of this a great portion is decomposed by the oxide of iron it meets with in the upper or reducing zone. The formation of this compound of carbon and nitrogen is doubtless due to the presence of soda and potash in the materials used, and it seems highly probable that these alkalies, or their metallic bases in the form of sodium and potassium cyanides being volatilised and partially deprived of their cyanogen, are condensed in the upper regions of the furnace and then returned to the hearth over and over again. From some cause the amount of cyanogen present varies considerably at different times, the point of generation apparently being at the hearth. Below is inserted in grammes the weight found per cubic metre of gas on six

consecutive days, four feet above the tuyeres, and to this is added the quantity remaining in the gases after leaving the furnace:—

							Average.
Grammes per cubic metre . . . .	19·00	12·93	17·32	11·34	20·61	9·16	15·06
Grammes in escaping gases . . . .	4·00	6·60	3·57	2·91	1·79	3·77	3·77

Upon another occasion the gases were examined for cyanogen at different depths, with the following results:—

Height above the hearth . . . . .	8 feet.	24 feet.	52½ feet.	60 feet.	Escaping pipe.
Grammes per cubic metre . . . . .	49·06	15·76	7·67	5·94	4·73

Having regard to the value of cyanogen in the arts, it is questionable whether its production, in the way described, has received all the attention it has deserved.

#### AMMONIA IN THE BLAST FURNACE.

In furnaces which are fed with coke, small quantities of ammoniacal salts are detected in the gases. When raw coal is the fuel used, compounds of ammonia, chiefly sulphide, are given off in such a volume that the gases are passed through huge condensers, and the alkali so obtained is treated with sulphuric acid and delivered to commerce in the form of sulphate. The weight of this substance thus obtained amounts to about 50 lb. per ton of pig iron made.

#### FUME GIVEN OFF FROM BLAST FURNACES.

After the gases have been used as a fuel for raising steam and heating the air, there is emitted from the chimneys vast volumes of white smoke. Of this large quantities condense in the flues, &c., and its removal is a source of some expense. Naturally this condensed matter varies in composition and no doubt in quantity according to the nature of the ores employed. By means of an air-pump a certain volume of gas from a Cleveland furnace was drawn through water. The matter condensed was partly insoluble and partly soluble in water, about half of each. They had the following composition:—

	Insoluble in Water.	Soluble in Water.
Silica . . . . .	11·00	1·37
Alumina and ferric oxide . . . . .	10·76	12·20
Lime . . . . .	2·06	Trace
Magnesia . . . . .	Trace	Trace
Oxide of zinc . . . . .	13·28	4·58
Alkaline salts . . . . .	3·07	..
Carbon dioxide . . . . .	7·00	..
Chlorine . . . . .	..	0·57
Sulphuric acid . . . . .	..	0·59
Sodium and potassium carbonates . . . . .	..	22·90
Loss on heating . . . . .	..	10·46
	47·17	52·67
	Total . . . . . 99·84	

It has been attempted, in the present contribution to the work of your Society, to establish for the blast furnace a character for an economical use of fuel. At the same time it has been proved that the duty performed is by no means equivalent to the whole of the useful effect which coke is capable of affording. Taking a ton as being able to produce 20 cwt. of pig iron from Cleveland ironstone, this, after an allowance for ash, &c., represents, when burnt to carbon dioxide, 147,200 calories, whereas something like 90,000 calories has been the limit of the power obtained. This apparent sacrifice of nearly 40 per cent. is incurred by what is considered the physical impossibility of bringing, in this particular process, the whole of the carbon burnt to its highest point of saturation with oxygen.

Forty years ago this unexpended energy was not turned to any useful account. This loss is now avoided by burning, under the boilers and in the hot-air stoves, the carbon escaping from the furnace as combustible monoxide. By this beautiful application of what was a waste product, all the mechanical power needed at the works is obtained, at the same time that the blast is heated, and these advantages are accompanied by a considerable saving of labour. With the present improved form of furnace the coal consumed for these two purposes would be much less than formerly, but even now it would not be much short of 10 cwt. per ton of metal. This calculation is based on the steam engines being on the non-condensing principle, but assisted with condensers, steam enough is raised to do one-fourth more duty than that called for at the furnaces.

When fire-brick stoves supply the heat to the blast, the loss at the chimneys is about one-half of what it is with those of iron pipes. In point of fact at the former, the temperature of the products of consumption does not greatly exceed that required for maintaining a good draught.

There remains, however, as always happens, a considerable loss at the boiler chimneys, but this at the Clarence Works is utilised by applying the waste heat for the evaporation of brine. A similar use is about being tried, at the same place, with the heat contained in the molten slag before it is thrown over the spoil heap.

P.S.—The length to which this address grew prevented my going into the reasons for doubting the formation of any large quantity of  $\text{CO}_2$  at the tuyeres, as stated by Roseoe and Schorlemmer. My friend Ritter von Tunner has also, I think, expressed a similar opinion. As a question of heat evolution, within a very small area, the formation of  $\text{CO}_2$ , or the reverse, is immaterial, because as is stated by these chemists, any  $\text{CO}_2$  so produced is rapidly converted into  $\text{CO}$ .

---

Table II.—At the foot of the page is an estimate of the heat evolved by the combustion of the fuel to which is added that carried into the furnace by the blast. The first line in this account shows the number of calories produced by the whole of the carbon of the fuel into CO less the quantity which has been carried off by the CO<sub>2</sub> of the limestone. The second line sets forth the additional heat afforded by the conversion of such a portion of the C in the CO as analysis indicates has been changed into CO<sub>2</sub>, and the third represents the heat in the blast.

The total carbon in the gases, in the tenth line of the page, is divided into the ascertained proportion of CO and CO<sub>2</sub>, and from these the quantity of oxygen present is calculated. This oxygen is contributed partly by the minerals and partly by the blast. That contained in the former, being calculated, is deducted from the whole, and the difference is considered as due to the atmospheric air of the blast. An estimate of the nitrogen is then made, and from all these factors the weight of the blast and of the escaping gases is easily obtained.

Following the estimate of the heat generated is a division showing the value of each unit of fuel used and from what source such value is derived, and lastly the relation in weights between C as CO and C as CO<sub>2</sub> is added: that in column A being 1 of C as CO<sub>2</sub> to 6.12 as CO; B, 1 of C as CO<sub>2</sub> to 3.74 of C as CO, and so on.

G represents a furnace working on English hematite ore, inserted as a comparative test of general correctness of mode in the other calculations.

\* 1,068 cal. is heat of combustion of 1 lb. of charcoal.

Mr. E. RIDER COOK, in moving a vote of thanks to the President, said that though the subject treated was strange to himself, he could see that it was of great interest to those who were concerned with or understood the subject. There was, however, one feature of the paper which had struck him, as it probably had also struck other members not intimately acquainted with the iron manufacture. It was that in the paper just read they had a striking illustration of the results of the application of science and accurate knowledge to a particular trade, and saw that the effect upon that trade was precisely similar to that which followed a similar course in the case of other industries. The general public would think as they saw the great blast furnaces at work that the smelting of iron could hardly involve a chemical operation. They would probably imagine, as they saw the heaps of coal and metal, and rough-and-ready beings tumbling them into the huge furnaces, that something was going on which could not have much connexion with the laboratory or with chemical science. But the paper had proved to him at any rate that where able men like the President had brought science and chemical knowledge to bear upon this rough operation, they had been rewarded by commercial prosperity in the saving of fuel. It had also shown him that where certain men without having chemical knowledge had yet been able to effect great improvements in the manufacture, subsequent investigation had nevertheless shown that unconsciously the improvers had been working on scientific lines. The lesson they ought to draw from the paper was that each member should seek to cultivate a stronger faith in the principles which the Society was intended to teach; that whether the substances they were dealing with were chemically combined or not, the laws of science might be brought to bear upon them with advantage; that the old system of rule of thumb might always be improved upon by those who acquainted themselves with the laws of nature and to the best of their ability brought them to bear upon the various industries with which they had to do.

Mr. LUDWIG MOND said that he rose with great pleasure to second the motion for a hearty vote of thanks to the President for the highly interesting and instructive address to which it had been the privilege of the members to listen. Sir Lowthian Bell had laid before them the work of his lifetime, together with his latest results and his latest opinions; and all those who were concerned in the manufacture of iron, or the treatment of masses of material by heat, or generally in the application of science to large industries and practical work, must have followed the address with the utmost interest. It was unnecessary for him to dwell upon the importance of the paper for the particular industry to which it referred; but he wished to point out the immense importance which the paper proved of investigating step by step all that happened in an industrial process and apparatus, however simple they might appear to be on paper (and nothing could be simpler than the reduction of iron by carbon as described in the olden times), and thus establish what the consecutive steps of the process really were. It was only by proceeding in that manner, and thus gaining an accurate knowledge of the complications really underlying what was apparently simple, that the best possible industrial results could be attained.

The motion having been put and carried by acclamation,

The PRESIDENT said in reply that his friends the mover and seconder of the vote had each endeavoured to commend themselves to the gratitude of the meeting by making a short speech, and he would endeavour to earn even deeper gratitude by making a still shorter one. He would merely say, therefore, that he had been agreeably impressed by the kind attention which the members had paid to the address which he had prepared for the occasion. He had certainly learned one good lesson from the Latin studies of his early days. It was expressed in the line: *Rerum cognoscere causas*, and he had ever since thought it desirable to endeavour to ascertain at the time the cause of any phenomena in which he was interested. He would only say in conclusion that he felt very grateful to the members

for their vote of thanks; for if he talked for half an hour he could not add to, and might weaken, that expression of his feelings.

The SECRETARY then read the report of the scrutators, which showed that 176 ballot papers had been sent in, and that the following had been elected to fill six vacancies among the ordinary members of Council:—Mr. A. H. Allen, Mr. H. Grimshaw, Professor R. Meldola, F.R.S., Mr. E. K. Muspratt, Mr. T. L. Patterson, and Mr. T. W. Stuart.

The following is a list of the Council for 1890–91:—

*President and Treasurer.*

E. Rider Cook.

*Vice-Presidents.*

Sir Lowthian Bell, Bart, F.R.S.	Ludwig Mond.
R. Forbes Carpenter.	Dr. Hugo Muller, F.R.S.
Prof. James Dewar, F.R.S.	B. E. R. Newlands.
James Duncan.	Dr. W. H. Perkin, F.R.S.
David Howard.	Dr. Edw. Schunck, F.R.S.
S. H. Johnson.	J. C. Stevenson, M.P.

*Ordinary Members of Council.*

A. H. Allen.	Prof. R. Meldola, F.R.S.
L. Archbutt.	E. K. Muspratt.
S. B. Boulton.	T. L. Patterson.
Jno. Brock.	Jno. Pattinson.
Jno. Calderwood.	Jno. Spiller.
H. Grimshaw.	T. W. Stuart.

*Foreign Secretary.*

Dr. Ferdinand Hutter.

*ELECTION OF AUDITORS.*

Mr. S. H. JOHNSON moved that Messrs. Theobald Bros. and Miall, Chartered Accountants, be re-elected auditors for the ensuing year. The motion was seconded by Mr. T. TYLER and carried unanimously.

*ANNUAL GENERAL MEETING FOR 1891.*

Mr. T. TYLER moved that the Society meet at Birmingham in 1891. Letters received from the Chairman of the Birmingham Section (who was prevented by indisposition from attending the present meeting) and from various gentlemen connected with the town made him feel quite sure that the Society would receive such a welcome there as the reputation of the town for hospitality would lead one to expect.

Mr. R. B. BATTY seconded the motion, which was carried unanimously.

The PRESIDENT then called upon the meeting for a hearty vote of thanks to the Senate of University College. Although such a vote was generally regarded as mere matter of form, it was only proper to express to the gentlemen connected with that magnificent establishment the assurance of the members' complete appreciation of what they had done towards the reception. Judging of their sentiments in that direction by what they had done for the cause of education by the construction and maintenance of that splendid building, he felt sure that those gentlemen must take a sufficient interest in the visit of the Society.

Mr. NORMAN TATE had much pleasure in seconding the vote proposed by the President. He felt sure that all the members present must feel pleasure in noting what had been done at Nottingham in the way of giving scientific instruction which would help forward the progress of that industrial chemistry in which they all felt so deep an interest.

The vote of thanks having been passed unanimously,

The MAYOR said that on behalf of the committee entrusted with the management of the College he thanked the Society for the way in which their services had been appreciated. As representing the Corporation, he felt proud that they were in a position to receive the Society in an establishment like that in which they were then assembled.

He believed that he might say without fear of contradiction that the Corporation of Nottingham was the only one that had had the courage to do what they had done, namely, to work a University College. There were other colleges in existence which no doubt far exceeded theirs in magnitude and usefulness, but none of them had been built by the town and for the town. Other similar institutions elsewhere were built and worked by private enterprise or contributions; but that in which they were now assembled was built by the town's money, and would, he hoped, do good service to the town and to the Society represented there that day.

### VISITS TO WORKS.

#### VISIT TO THE MIDLAND RAILWAY WORKS, DERBY.

About 120 members proceeded by train to Derby to visit the works of the Midland Railway Company, travelling in saloon carriages provided by the Nottingham Section. On arrival at Derby, the party proceeded to the Midland Hotel, and, by invitation of the Nottingham Section, partook of luncheon. After luncheon, the President and a party of about 100 members proceeded to the locomotive works, where they were met by Mr. S. W. Johnson, the locomotive superintendent, Mr. Holt, the works manager, and other officials. Time did not permit of more than a hurried inspection of the extensive works, which cover nearly 12 acres of ground adjoining the Midland Railway station, and give employment to more than 3,000 men. Commencing with a visit to the laboratory, and walking through the millwrights' shop, the party proceeded to the mess rooms, capable of accommodating 700, 500, and 300 men respectively, in which a staff of cooks find constant employment in the preparation of the meals of those workmen who live at a distance. The party thence proceeded to the spring shop, and through the wheel and tyre turning shops, and the smithy, to the boiler shop, where the steam rivetting machine, the powerful shearing machine, and the machine for drilling the holes for boiler stays evoked considerable interest. Escaping from the deafening din of the boiler-smiths' hammers, the route was continued through the smaller erecting shops, the press shop, the coppersmiths' shop, and the brass foundry, to the iron foundry, a lofty building 180 ft. long by 90 ft. wide, where about 310 tons of cylinders, chairs, and all kinds of general castings are turned out every week. Adjoining the iron foundry were seen the gas works which supply the various shops, as well as the offices and station, with gas, the quantity made averaging about  $1\frac{1}{2}$  million cubic feet per week. The next shop visited was the large erecting shop, 150 ft. broad by 450 ft. long, covered by a roof of three spans, and capable of accommodating 90 engines in progress of construction and undergoing repairs. The six powerful travelling cranes, each capable of lifting 25 tons, and worked by endless cords, were objects of interest. The adjoining fitting, turning, and brass-finishing shop was much admired. This shop has four spans, each 40 ft. wide by 450 ft. long, and contains no less than 460 separate machines driven by a quite bewildering mass of belting. The many interesting machines in this shop would have repaid a more lengthened inspection, but as time pressed the party proceeded to the painting shop, where an opportunity was afforded the members of viewing and examining a newly-finished engine and tender similar to that which gained the "Grand Prix" at the recent Paris Exhibition, and which was very much admired. A full description of this engine appeared in "Engineering" on March 2nd and 16th, 1888. A walk through the new engine shed, where accommodation is provided for 48 engines to get up steam and stand in readiness for their respective trains, brought the visit to a close.

A smaller party of about 20 members had in the meantime proceeded to the carriage works, where the manager, Mr. Osborne, and other officials took charge of the party and conducted them through the various shops. The carriage works of the Midland Railway Company are situated about half a mile south of Derby station, and cover  $14\frac{1}{2}$  acres of ground with  $10\frac{1}{2}$  miles of sidings and

rails. They are the largest of their kind in the kingdom, and consist of seven large shops, four on the west side devoted entirely to the preparation of timber, putting together of material, and finishing off of vehicles, and three on the east side devoted entirely to metal work; all the shops being conveniently arranged for the direct transmission of work from one to another by means of steam traversers, so as to avoid all unnecessary labour in passing backwards and forwards. The sawing and wood-working mill is 320 ft. long by 200 ft. broad. The floor is supported on more than 500 cast-iron columns, and all the main shafting, pulleys, belting, &c., are situated in the cellar below. This mill contains about 100 machines specially designed for the various operations of wood working. Next in order is the wagon shop, of the same dimensions as the saw mill, and here the prepared timber from the mill and the prepared metal-work from the machine shop are put together in the form of waggon. The demand for waggon by the Midland Railway Company, 66 per cent. of whose traffic is goods, is very great, and has so much increased of late years that it has been found necessary to build a new shop, considerably larger than any of the older shops, which is entirely devoted to wagon building, and some idea of the facilities afforded for this kind of work may be gathered from the fact that on an average one new wagon is completed every 20 minutes. In the next shop to the old wagon shop the building of carriages is carried on, and the finished carriages pass thence to the painting and trimming shop where they undergo no fewer than 25 different operations of priming, filling-up, rubbing down, painting, varnishing, &c., to enable them to withstand the weather and present a satisfactory appearance. The lighter part of the upholstery work and the French polishing connected with the vehicles is carried out by women and girls, who work in a separate portion of this building with separate mess-rooms and offices. The iron foundry, smithy, bolt and spring shop, wheel-tying shop, and machine and fitting shop were all inspected, and after a most interesting afternoon the members joined the larger section of the party from the locomotive works and returned to Nottingham in the saloon carriages in which they came.

#### MESSRS. J. AND R. MORLEY AND CO.

Visits were also paid by some of the members to the hosiery factories in Manvers Street and Handel Street belonging to the well-known firm of Messrs. J. and R. Morley, whose manufactories have been fixed in Nottingham and its neighbourhood for almost a century.

In these factories the various processes of manufacture were watched with much interest, special attention being given to the new patent self-acting fashioning frames, of which this firm, in their various factories, are said to have the largest plant in the world.

Machines for making the well-known Derby-ribbed work, and also the numerous kinds of natural wool underclothing now so largely used, were closely inspected by the visitors, who expressed much pleasure at what was shown to them.

In the Handel Street factory, in addition to the making of hosiery goods, the process of cotton spinning is also carried on, and this added to the interest of the visit.

#### TRENT BRIDGE LEATHER WORKS.

A party of about 25 members assembled at the works of Messrs. Turney Brothers, Limited, leather manufacturers, Trent Bridge, and were shown over by Mr. J. T. Wood.

Commencing with skins as they entered the works from the fellmongers' yards, the party followed them through the various processes—the liming, fleshing, splitting, bating, and tanning (both by sun and bark).

They then inspected the manufacture of chamois or wash-leather by means of fish oil, the felling mills, hydraulic presses, and the scouring of the leather, and saw the finished article being packed in the warehouses for export.

The dyeing and finishing of the leather for bookbinding, purse-making, boot uppers, boot linings, and hat leathers was next inspected, and a new product which the firm are manufacturing, the glazed Dongola leather for the upper leathers of high class boots, attracted considerable attention.

The salting or pickling of skins for the American market was next examined, and after looking at the laboratory the party went away expressing themselves very pleased with their visit.

The following works were also open for inspection:—

Messrs. Blackburn's Hosiery Machine Works, and Messrs. Lindley, Wright, and Cox's Lace and Hosiery Finishing Works.

#### CONVERSAZIONE AT THE CASTLE.

On Wednesday evening the Mayor of Nottingham (Alderman Goldschmidt) recognised the presence of the Society in the town by giving a conversazione in the Castle Museum and Art Gallery. Upwards of 850 invitations were issued, and of this number about 800, including 200 members of the Society, accepted the kind hospitality of the Mayor. Eight o'clock was the hour fixed for the commencement. The arrangements in every respect were admirable, both inside and outside the Castle. The guests were received in the Long Gallery at the north end by the Mayor and Miss Goldschmidt, in the absence of the Mayoress, who was unfortunately too indisposed to be present. The Mayor's party consisted of Lady Turney, the Sheriff (Councillor Pullman) and Mrs. Pullman, Mrs. S. G. Johnson, and Mrs. Lewis. The gallery was brilliantly lighted, and soon the scene was a very pleasing one. Behind the Mayor and party were a number of palms, plants, and flowers, and throughout the rooms and on the steps were similar banks of colour. From the Long Gallery the guests could promenade at will through the Water Colour Gallery, and into the Dawson Gallery, where light refreshments were served. The guests could wander still further, either into the well-lighted museum to admire the many interesting curiosities, or into the second refreshment room on the ground floor, and so on to the East Terrace. From thence gentlemen and their more timid companions, who cared to venture under ground, could be conducted by an attendant to "Mortimer's Hole." Another opportunity was also given to those who chose to seek the refreshing, but somewhat cold breezes of the night, the entrance to the Castle roof being thrown open. At no period of the evening were the galleries uncomfortably crowded, and the absence of this almost inevitable feature of all such functions was doubtless matter of congratulation on the part of the assembled guests. Mr. Watson's band played capital selections of music in the Water Colour Gallery. From the Castle green, during the early portion of the evening, there also floated the sweet strains of a band, which at dusk played inside the Castle. It was not until 10 o'clock that the loud hum of conversation noticeably lessened, and the pleasant lounges began to be forsaken; but after that hour the guests gradually dispersed, the conversazione concluding at 11 o'clock.

#### SECOND DAY.

##### VISIT TO THE BURTON BREWERIES.

On Thursday morning a party of about 100 members proceeded to Burton, where they were met by Messrs. Matthews and Lott, secretaries of the reception committee. From the station the party proceeded in sections of about 20 to the breweries of Messrs. S. Allsopp and Sons, Lim., Messrs. Bass, Ratcliffe, and Gretton, Lim., Messrs. Ind, Coope, & Co., Lim., Messrs. Salt & Co., and Messrs. Worthington & Co., Lim. At the several breweries they were received by Dr. Harrow, Mr. T. C. Martin, and Mr. Strachan (Allsopp's); Mr. C. O'Sullivan, Mr. J. O'Sullivan, Mr. Walter Odling, and Mr. Jas. McGregor (Bass's); Mr. Skilton and Mr. Lloyd (Ind, Coope's); Mr. Adrian J. Brown, Mr. H. Daniel, and Mr. W. Newton (Salt's); and Dr. G. Harris Morris, Mr. W. Swinnerton, and Mr. C. Fletcher (Worthington's). A thorough inspection from the malt-house to the tasting-room was afforded in each case, and the familiar process of brewing was exhibited under the most favourable condition that a perfect water and the highest technical skill can supply.

After two o'clock the various parties met at the St. Paul's Institute where, by the hospitality of the five firms above

mentioned, members partook of a sumptuous luncheon. At the conclusion of the repast Mr. Ludwig Mond and Mr. Muspratt proposed and seconded in brief speeches a warm vote of thanks to the five firms, their hosts. Mr. David Howard asked leave to include in this the names of those who had received and escorted the various parties. The votes of thanks were carried by acclamation. Mr. C. O'Sullivan (Messrs. Bass & Co.), Mr. Martin (Messrs. Allsopp & Co.), and Mr. Lott responded.

##### MESSRS. SAMUEL ALLSOPP AND SONS' BREWERIES.

Those members visiting the breweries of this firm were first conducted to the new brewery. Besides the fine offices and the huge storeroom, which is capable of holding over 30,000 casks, the capacious well, the largest in Burton, and having a diameter of 46 ft., formed an object of interest. The party was now taken by a special train to the middle yard, where, after seeing the stables, it was shown through the general stores. The train then steamed across to the old brewery, and here Mr. Martin was able to explain in detail the brewing process, commencing with a mash which was carried out whilst the party looked on. Several of the members were much interested in the special washing treatment this firm subjects the yeast to which is not utilised on the premises. It is thus possible to obtain a higher price for this material than could otherwise be obtained. In connexion with this Mr. Martin said he was glad to know that some members of the Society were devoting their attention to the more advantageous disposal of brewery by-products, and hoped they might be successful in finding a means of replacing German yeast by a similar article made in this country from brewer's yeast, and also make spent hops and grains of more service to the farmers.

Returning to the new brewery, the party visited the two large union rooms, holding respectively 1,624 and 1,376 casks, and capable of cleansing nearly 500,000 gallons of ale at one time; and the enormous racking hall, 400 ft. long by 100 ft. wide.

Before leaving the premises, a visit was paid to the laboratory, where Dr. Harrow, successor to the late Dr. Griess, with whom he had for many years been working, pointed out many of the more peculiar pieces of apparatus and contrivances for analysing beer and the materials necessary for its production.

##### MESSRS. BASS, RATCLIFF, AND GRETTON, LIMITED, BREWERIES.

Messrs. Bass and Co. have three breweries in Burton, the Old, the Middle, and the New—in each of which the process of brewing is carried on independently and completely. The capacity of the three together is at present somewhat over 30,000 barrels weekly.

The first department visited was the cooperage, adjoining the Middle brewery. This was seen in full work, about 40,000 casks being required annually for the export trade alone. There was more machinery in this department than is usually seen in connexion with this industry, and the method of closing the staves, after one end of the cask had been secured, by surrounding it with a powerful chain and tightening this by hydraulic power, was watched with some interest. The party then proceeded to the extensive hop-stores, with about 800 tons of hops in stock, kept in the dark to preserve the flavour.

Underneath these were the ale stores, where samples were produced for examination by the visitors. From this point the party was conveyed in waggons by a private railway line round the town to the Old brewery.

Here the pumping machinery for the water supply was first inspected; there being separate sets of pumping machinery for the brewing, the cooling, and the washing water. The brewing water is raised from wells, adjoining the Shobnall Maltings, about a mile and a half away; this is pumped into the brewing tanks, while the cooling and washing waters are stored in large service tanks at the top of a tower. Burton water is drawn from the new red sandstone foundation. This sandstone contains mud and gypsum, from which the water dissolves calcium sulphate to the extent of about 200 grains per gallon, making it extremely hard. It is also free from organic matter, a

most important fact as affecting the fermentation. It was formerly supposed that the presence of this calcium sulphate was advantageous, as hindering the solution of the albuminous portions of the malt; but experiments have since shown that this is not so, and that the chief merit of the calcium sulphate lies rather in its antiseptic properties, which serve to keep the fermentation under better control. Near the pumping engines are situated the boilers to supply the hot water required for the mashing process.

In the top storey of the Old brewery the crushed malt is passed in thin streams into the mash tub, where it is treated with hot water, the mixture being kept in motion by an agitator revolving on a vertical axis, on the arms of which again revolve paddle-wheels. The room visited contained seven mash tubs, each capable of mashing 60 quarters of malt. The "wort" flows thence through a perforated bottom to the "underback," a species of storage reservoir, and thence to the "coppers," where it is boiled with hops. These coppers are heated by an open fire. Thence the boiled wort flows to the hop-back, in which the hops are retained by a perforated false bottom; it is pumped on to the "coolers," large shallow trays of wood; it then flows into the "refrigerators," consisting of tanks containing great lengths of copper tubing through which a current of cold water flows. The wort having reached a proper temperature now passes into the "fermenting squares," where yeast is added, and where the evolution of carbonic acid is very marked. There are on one floor 160 of these "squares," each of 50 barrels capacity—a very large plant. From the squares the beer is allowed to flow, at the proper time, into the "union room," a feature peculiar to Burton. This "union room" contains rows of large casks communicating in "sets," and when in work kept constantly full of beer. From the top of each cask issues a pipe which rises a few feet and then dips over into a trough. In these casks fermentation is completed, and the yeast is gradually forced up the ascension pipe from the full cask and is collected and retained in the troughs. The temperature of both casks and troughs is regulated by a current of cold water passing through tubes inserted in them. From these the beer is drawn off by a moveable cock which so projects upwards into the cask that the sediment is not disturbed. The union room is 125 yards square, and can contain 2,500 casks, each of 160 gallons capacity. From this room the beer passes into the "racking room," where the process of brewing ends, the finished beer being here "racked" from large tanks into casks of various sizes for use.

The party next proceeded to view the private laboratory of Mr. C. O'Sullivan, F.R.S., who manages this brewery and directs the scientific department connected with the whole concern, and then resumed their places in the waggons and were conveyed to Shobnall. The firm own 32 maltings at Burton, of which seven are at Shobnall—all connected—and they own and work many other maltings at Lincoln and elsewhere. Here barley is steeped in warm water, then allowed to germinate on large floors, and finally kiln-dried at a temperature increasing from 110° to 160° F. The capacity of the Shobnall Maltings is 60,000 quarters.

#### •MESSRS. IND, COOPE, AND CO.'S BREWERY.

The party which visited Messrs. Ind, Coope, and Company's brewery were ably conducted over the establishment by Mr. C. F. E. Skilton. The Burton work is, we believe, not so large as the same firm's brewery at Romford, but it struck us as being singularly compact and well arranged, and every department was a pattern of neatness and good order.

The visitors were taken first to the mashing rooms, of which there are two, containing four mashing tuns each, the total working capacity of which was stated to be about 360 quarters of malt. From these they proceeded to the rooms in which the wort from the mashing tuns was being boiled with its complement of hops in six huge coppers, each of about 110-barrel capacity. On the way to the next department the visitors examined the mill in which the malt is crushed by steel rollers, and from which it is distributed by means of hoppers to such of the mashing tuns as require feeding. Next were seen the two large cooling tanks, which are used for surface cooling only, a very simple floating arrangement being employed by means of which

the pipe that carries off the liquor to the refrigerators is kept just below the cooled surface. The new system of refrigerators adopted by the firm appear to be very ingenious and effective. Each apparatus (of which there were two of a series of four in work) consists of a stack of horizontal pipes through which cold water continually passes, the warm liquor trickling down from the top and passing over the edges of the series of pipes, finally leaving by a trough at the bottom cooled down to 58° F. From here the party was conducted to the hop store, passing on the way the new tanks for supplying hot water to the mash tuns. Of these there are nine, each of 3,400 gallons. Traversing the larger of the two fermenting rooms (containing 32 tanks) the visitors proceeded to the "union room," wherein is conducted the process of final fermentation and cleansing by the Burton method, details of which are given in the paragraph relating to the visit to Messrs. Bass and Co. It should be mentioned, however, that in one "union room" Messrs. Ind, Coope, and Co. have adopted the plan of cooling by means of pipes running along above the barrels; but it was stated that the method does not work so well as the old system of passing cold water through pipes traversing the barrels. The finished beer is drawn off from these barrels and run through troughs into the "racking vaults" beneath, where it is casked.

After inspecting the Reece's freezing apparatus, the yeast pressing room, and the laboratory, the visitors retired to the stores, where they tasted samples of the various ales produced by the firm, finishing with a bumper of the special "Jubilee brew."

#### THOMAS SALT AND CO.'S BREWERY.

Those visiting Messrs. Thos. Salt and Co.'s brewery first drove to the storerooms in Wetmore Road. Thence the party was conducted to the cooperage, where, after inspecting the unheading, washing and steaming of casks, they examined numerous machines for cutting and preparing the oak staves so that they might be put together into casks of various sizes. The malt-houses were next visited, and although in summer time malting is not carried on, the process was thoroughly explained. After this, the members were rapidly conveyed in a railway waggon to the brewery proper—about half a mile away. In order were seen first the crnshing of the malt, attention being specially directed to the grooved or fluted steel rollers used by this firm in preference to the smooth ones elsewhere in vogue. Next the raising of the malt by automatic elevators. Then the mash tubs, five in number, each capable of holding 60 quarters of malt and 120 barrels of water. Here attention was called to the device by which the brewer in charge could control both temperature and volume of water used. Then came the copper-house containing eight large coppers, whence the boiled wort is pumped to the top of the building and run into large shallow copper coolers and subsequently over refrigerating pipes, and so down to the "square" room. As elsewhere in Burton fermentation is carried on here first in "squares" or open vats, and subsequently in casks or "unions," where the finished ale is cleared of its yeast. Messrs. Salt's "union" room is capable of holding as much as 3,600 barrels of ale at one time. Below is the racking-room, one of the largest of its kind in Burton, where the finished ale is run into wooden rounds, holding 100 barrels each, prior to being put into casks. After inspecting the yeast presses the party proceeded to the St. Paul's Institute for lunch.

#### WORTHINGTON AND CO.'S BREWERY.

The party for Messrs. Worthington and Co., Limited, were conveyed in breaks to the brewery premises in High Street. Here the stores were first visited. From the stores the party proceeded through the maltings. Owing to the time of year no malting operations were in progress, but the visitors had an opportunity of examining the malt-houses, the largest of which, with a cistern of 180 quarters capacity, and floors capable of receiving a steep of this quantity every four days, was much admired. The machinery for screening, cleaning, and grading the barley was also inspected, and after passing through the barley and malt stores, capable of holding 13,000 quarters, and from which the barley is

distributed to the different malt-houses by means of a travelling india-rubber endless band, the party visited the laboratory. Here the members were naturally much interested in the complete arrangements for the examination and analysis of wort, beer, malt, &c. The room fitted up specially for the pure cultivation of yeast by Dr. Hansen's method attracted great attention, and it was mentioned that the company had brewed as many as 6,000 barrels of beer with different varieties of pure yeast, each cultivated from a single cell. The results, however, were not sufficiently satisfactory to encourage a more extended use of pure cultivated yeast. Leaving the laboratory, the party passed on to the brewery on the opposite side of High Street, and, starting with the malt-mill, which contains a pair of east-iron rollers capable of crushing 50 quarters of malt per hour, the members followed the grist into the mash-room, containing three mash tuns, each fitted with a Steel's mashing machine capable of mashing 80 quarters in from 10 to 12 minutes. From the mash tuns the wort was followed to the coppers, the largest of which holds 160 barrels, and where it is boiled with the necessary amount of hops. From the coppers the party proceeded to the hop-back, where the hops are strained from the wort, thence to the cooling room, and on to the refrigerators and fermenting room. Here the various devices to prevent, as far as possible, contamination of the wort at this point were explained to the party, and it was stated that the fermenting room was the most complete and best fitted in England. From the fermenting room the partially fermented wort passes to the "union casks," in which the primary fermentation is completed. The "union cask" system is peculiar to Burton and its immediate neighbourhood, and it is said that the character of the beers for which Burton is famed is largely due to this system. From the "unions" the beer is run into racking-squares and thence into the casks ready for consumption or storage, as the case may be. The hop- and barm-presses and other adjuncts to the main brewing process having been inspected the party proceeded to the cooperage and to the washing-out sheds, where all casks are thoroughly washed by several processes before being used in the brewery. The very complete arrangements for testing, washing, and drying casks excited great interest among the members, and after examination of these as time would allow, the party entered railway trucks attached to one of the company's locomotives, and after passing through the entire brewery premises made a complete circuit of the town, and by passing the premises of the other Burton firms were enabled to form an idea of how completely the town is devoted to the manufacture of beer.

#### VISIT TO THE BUTTERLEY IRON WORKS.

This alternative visit was participated in by about 30 members on Thursday afternoon, July 10th.

They were conducted round the works by the manager and others of the firm, and the arrangements were such that the critical or finishing stages of several important processes could be seen to advantage by the visitors. Gaseous fuel is largely consumed in the works and is generated in a series of Wilson gas-producers. Near to and fired by these producers were several Martin-Siemens steel furnaces, and the pouring of the molten steel into moulds to form ingot-steel excited much interest. Perhaps the most beautiful sight was that of the intensely-heated molten metal in the furnaces themselves, as looked at through blue cobalt glass, for the eyes of the visitors could not endure the intense glare of white light without such aid.

A great deal of interest was also evinced in the processes of manufacture of bar and rod iron of various dimensions and grades, &c., as well as in the powerful and ingenious machinery for rolling, drawing, and other purposes. Several gigantic steam hammers were in operation, and as the evidence of enormous economy both of time and labour by the use of this apparatus was witnessed, it was difficult to regard these giants of force, as well as of skill and ingenuity, without a mingled feeling of admiration and reverence for the master mind, of which we have been so recently bereft, and who invented and brought the steam hammer to perfection, and when Watt, of Glasgow, and Stevenson, of

Tyneside, are henceforth spoken of, the association of British engineering genius will not be complete without the addition of the name of Nasmyth, of Manchester.

Every attention was shown to the visitors, and much pains taken to answer the numerous questions asked.

#### MESSES. MAXLOVE, ALLIOTT, FRYER, & CO.

The engineering works of this firm in Nottingham were visited on Thursday afternoon. The visitors were first received in the drawing office, where were exhibited a number of elaborate arrangements of the complete plants necessary for the prosecution of various industries, including the most modern sugar factories, oil mill installations, steam laundries, &c.

Arrangements of machinery for the treatment of precipitated sewage sludge were also shown, and members had an opportunity of inspecting models of the most recent type of gas engine, known as the "Cycle."

A conspicuous object on first entering the erecting shops was the Passburg grains dryer, for drying brewers' grains. A factory is now being fitted up by the firm at Burton-on-Trent, in which four of these large machines are to be placed. A number of washing machines of various sorts, including rotary steam washers, Découdan steam ironers, &c., and some large filter presses for the Wolverhampton Corporation were also shown. These latter will yield one ton of pressed cake per hour from sewage sludge after lime treatment.

In a shop adjoining several centrifugal machines of various types were to be seen in motion, the cages being directly driven by small engines attached to the iron casing or pan, the whole being either suspended from small pillars secured to the foundations, or else allowed to slide about on "slippers" on small carefully faced plates attached to the floor. By these means the inevitable vibrations caused by the great speed of the engine are reduced to a minimum.

An apparatus which deserved some attention from those engaged in chemical pursuits was next inspected. The "inspissator," as it is called, is an invention of Mr. Fryer, and with it solutions readily injured by heat can be rapidly concentrated without the necessity of boiling in vacuo. To illustrate the process to the visitors some water was rapidly evaporated by direct fire at a temperature of 120° F. This particular apparatus was of small size, capable of being worked by hand, and heated by small gas jets, being, in fact, the size suitable for laboratories.

Newhall's conveyer dryers, for the extraction of the last remnant of moisture from sugar crystals, also attracted some considerable amount of attention, more especially as the arrangement can be used in conjunction with the ordinary granulators of the Newhall or Hersey type.

#### VISIT TO THE NOTTINGHAM MANUFACTURING COMPANY'S WORKS, STATION STREET.

The party was received by Mr. Heslop, the Managing Director, and he with the assistance of Mr. Taylor, the Manager of the Manufacturing Department, and other heads of the different departments, explained very fully the various processes by which stockings and underwear are produced.

A model of the machine principally in use in the first quarter of this century was first shown; and Mr. Heslop very briefly explained how hosiery machinery was originally let out to cottagers in the surrounding district, and how the rents were received as regularly as that of the cottage they occupied, and how, as a matter of fact, hosiery machinery was heritable property, and was often transferred to the daughters of the family as a portion of their dower.

Later on, as was the case with other hand-loom when steam was introduced as a motive power, heavier and faster machinery was invented, and the manufacture of hosiery was transferred to factories in the towns, the effect of which was graphically described in the "Times" of January 19th, 1852, an extract from which Mr. Heslop produced. When hosiery machinery was let out to villagers a man would produce on the average 12 pairs per week; from this a gradual improvement of machinery developed upon the same lines until a new departure was made by Cotton's

patent of 1864, when a machine was invented which eventually revolutionised the trade, notwithstanding the prejudices of manufacturers, which prejudices were strengthened by the knowledge that this machine must render almost useless all the expensive plants in the various factories in the town. The patent was purchased by the Nottingham Manufacturing Company, who afterwards disposed of a share of it to the firm of J. and R. Morley, of London and Nottingham, and the success the two firms had with the production from this machinery obliged outsiders to seek for licenses to work the patent. Year by year improvements were made, and at this factory a man with two apprentices now makes both plain and ribbed work of similar properly fashioned, or as ladies understand in knitting, narrowed make, at the rate of 1,000 pairs per week.

After the factory the party passed through the rough stock room, and were informed that the fearful competition in the manufacture of hosiery made it somewhat difficult to satisfy the requirements of the shareholders, and that the demands of labour rendered it probable that in the future capital would have to be satisfied with a smaller return.

After a walk through the warehouse, where the various articles were finished, folded, and put up, the party visited the finishing shop, engine house, and yarn cellars, and departed much gratified by the visit.

The following works were also open for inspection:—

The Birks Co.'s Embroidery Works, Messrs. Dobson's Lace Factory, Messrs. Lambert's Lace Dressing Rooms, the Midland Lace Co.'s Frilling Factory, and Messrs. Doughty's Lace Factory.

#### ANNUAL DINNER.

At 7.30 about 150 members assembled in the Exchange Hall—most generously granted for the occasion by the Mayor and Corporation of Nottingham—for the annual dinner.

The President, Sir Lowthian Bell, Bart., F.R.S., occupied the chair, supported by the Mayor of Nottingham (Mr. Alderman Goldschmidt), Mr. E. Rider Cook (President-elect), Messrs. Ludwig Mond, David Howard, and E. K. Mnspratt (past Presidents), Alderman Sir John Turney (Chairman of the Nottingham Section), Professor Clowes, D.Sc., and many other members of Council and the local committee.

The PRESIDENT, in proposing the first toast: "The Queen, the Prince of Wales, and the rest of the Royal Family," said that the most exalted personage in the realm had so endeared herself to the hearts of her subjects, and had so entirely gained the respect of the rest of the civilised world, that he need do no more to recommend her to the affectionate consideration of the company than simply pronounce the name of Her Majesty the Queen. He had had the honour of serving under the Prince of Wales on the occasion when the object in view was the progress of that knowledge which it was the aim and duty of the Society of Chemical Industry to cultivate and advance. He was sure that it was unnecessary for him to say anything further.

The toast having been drunk with musical honours,

The PRESIDENT next gave "The Town and Industry of Nottingham." It was, he said, about 25 years since he had last visited the town, and he had endeavoured during his short stay to acquaint himself as far as possible with its claims as regarded the prosperity of its industries. He must confess that if Nottingham's claims were judged by the progress which it had made during that 25 years, no amount of prosperity which it might receive would be in excess of its deserts. He had seen enormous progress in its public monuments; streets where there were no streets before; and roads which were a pattern of excellence to all the world. He had endeavoured to account for this by the fact that the town had at its head a public spirited and intellectual municipal body watching over its interests. But that would amount to very little if the endeavours of such a body were not backed up by the intelligence and goodwill of the inhabitants.

With regard to the particular branch of science with which they were specially concerned, no words of his could better recommend Nottingham to the favourable consideration of those engaged in chemical industry than did the town's own action in promoting the cause of science by the erection and endowment of one of the best appointed colleges of science in general, as well as chemistry, that he had ever seen. Some years ago, he had paid the highest compliment to the College of Science in Nottingham that could be paid by any one man. For when at Newcastle they wanted a principal for their college, they, on his advice, sought him in Nottingham, and took him away from there; and, in the absence of his friend Professor Garnett, he might venture to say that no man had better deserved the confidence of his council and the town of Newcastle than he had. But the toast assigned to him related more particularly perhaps to the industries of Nottingham. He was sorry to learn from sources which he could not possibly have misunderstood that one of the staple trades of the town was not in that commercial position which they and the country at large would like to see it enjoy. He, however, was one of those who were far from thinking that occasional periods of depression in any branch of industry were an unmixed evil. Those were the occasions which intelligent and brave men used for the purpose of advancing that branch of industry to which they devoted their lives by a steadfast and intelligent study of its special requirements. If one looked back for a few years into the history of any particular branch of industry one was astonished at the progress which had been made. Confining himself for the moment to the iron trade, he might mention that when he first entered it they thought it very clever to make one ton of iron with four tons of coal, and to produce 70 tons of iron a week. They were now able, using a refractory ore, to make a ton of iron with half the quantity of coal once used; and instead of making only 70 tons a week, they thought themselves badly used by their furnaces if they did not make more than 70 tons a day. With respect to the lace trade and the other industries of Nottingham, he, of course, could not speak with authority. He had for the first time in his life been that day permitted to inspect a manufactory devoted to the production of that useful article called leather, and carried on under the scientific guidance of his friend Sir John Turney. He never was more agreeably impressed with a branch of industry with which he was unfamiliar than on that occasion. In visiting the Midland Railway Works under the guidance of his friend Mr. Johnson, he had enjoyed a great treat, for it happened that he was a director of a railway in the North of England, and was in charge of what was known on that line as the locomotive committee. He had found at Derby an excellent laboratory, with a skilful chemist engaged in examining with the utmost care almost every article which entered into consumption on the Midland line. His friend Mr. Johnson would be grieved beyond measure if at any time he received a report showing that the metal out of which his tyres were made contained the 1,000th part of its weight more of phosphorus than he considered it prudent to have. He confidently asked the members to join him in drinking to the return and continuation of prosperity to the town of Nottingham, and with the toast he would couple the name of his friend the Mayor.

The MAYOR, in responding, said that he and his colleagues were extremely pleased to see the Society in Nottingham, and anything they had done to make the visit a pleasant one had been done in appreciation of the science which the members pursued. That science had, he took it—excepting perhaps engineering—done more than any other to develop the commerce of the country and to contribute to the comfort of the inhabitants. The President had told him that he would go even further, and say that even engineering could not get on without the aid of chemistry, and he fully believed that the Forth Bridge could not have been erected without the assistance of that science of which the company present were the votaries. As regarded the Corporation which he had the honour of representing, the Society had seen what had been done for science in the college in which they were received. They had seen also in that beautiful temple of

art on the Castle Rock what had been done for higher culture. Here rejoiced that the Corporation excelled all others in this, that they were not satisfied with only looking after the material welfare of the town, with providing good, well-paved, clean streets and capacious sewers, but their aims went higher, and they took care of the intellectual progress of the inhabitants. With respect to the commerce to which Sir Lowthian Bell had so pathetically referred, it was quite true that for the time being one of the principal industries of the town was under a cloud. But they did not despair. They had seen similar periods of depression before, and had overcome them; and he had no doubt whatever that they would ride over the storm on which they were tossed about at the present moment, and safely arrive in a well-sheltered harbour. That particular industry was to some extent connected with chemistry, since lace, like all textile manufactures, depended a good deal upon the art of dyeing. Formerly, dyeing operations used to be done by rule of thumb; but that period had passed away and everything now depended upon science. He sincerely hoped that the visit of the Society to Nottingham would stimulate those who were engaged in dyeing, and that henceforth they would not be satisfied with merely being abreast with their foreign competitors, but by dint of science surpass them in the race.

The Town Clerk (Mr. S. G. JOHNSON), in proposing the toast of "The Society of Chemical Industry," said that he wished that the Society could have visited the town when it was at the flood of prosperity rather than in the ebb of adversity. But an old divine had said that where one would be found who could bear prosperity well, ten would be found who could bear adversity well. That saying was recalled to his memory by the President's remarks; and he quite believed that times of adversity had been the times when Nottingham men had renewed their strength and risen against adverse circumstances to new prosperity. It might, indeed, be fortunate that the Society had come at such a period, because they could commend to the members many circumstances in which they might find means to encourage them. They had there, in the centre of England, a very fine town, hardly to be surpassed in the manufacturing centres of the country; a very healthy town; a town which they had endeavoured to beautify, and in which they had done all they could for the intellectual growth of the inhabitants. They had there all the chief materials of England's prosperity: iron, coal, railway and water communication, and above all a people who were hard headed, strong handed, and willing to work with intelligence, industry, and perseverance. He trusted that some one might find the means of utilising all the material he had named, and thus make a good thing for the town and for himself. He fully endorsed what the Mayor had said respecting the value of the Society's work, and was glad to find that the members could sink all small differences and jealousies, and meet on common ground to interchange ideas and discoveries, instead of bottling them up in their own breasts. He felt that he was addressing men who had gone out to wrest from nature her great secrets, and who had struggled hard in their laboratories, for it could not be supposed that they were usually occupied as comfortably and pleasantly as he saw them at that moment. But he thought of them in their workshops, smithies, and laboratories, working day by day to acquire further knowledge for the benefit of that great humanity of which they all formed a part, and he knew that what they had done was only an earnest of what they would yet do. He need not use many words in commending a toast which practically meant themselves; but he had the pleasure of coupling with that toast the name of Mr. Rider Cook, who had been their Hon. Treasurer for 10 years, who had helped to establish the Society, and whom they had that day chosen as their next President. He was sure that under his guidance the Society would continue to prosper.

Mr. E. RIDER COOK said that he felt it a very high honour to be called upon to respond to the toast so ably proposed by the Town Clerk of Nottingham, a gentleman whose reputation was not confined to that very energetic

town, but was well known throughout England. He felt that he had a great deal more to thank Nottingham for than the mere drinking of that toast. Ever since he had set foot in the town, his mind had been full of gratitude for the princely and magnificent manner in which the Society had been entertained. When he received the papers relating to the meeting, he felt that the committee who had the matter in hand, had not only bestowed an immense amount of thought on the task of making the gathering a success, but had translated that thought into very efficient action. But when he arrived in the town and found that the University College, the Museum, the Arboretum, the Public Library, and the other institutions open to them, were all the work of the Corporation, he felt that they were going through an entirely new experience in receiving the hospitality of a municipal body, and that the example set by Nottingham was one which might well be followed by other municipalities throughout the country. He did not believe in centralisation. He believed in the people of a place managing their own affairs for themselves; and when he found that the Mayor and Corporation of Nottingham had been actuated by a desire not only to make their city beautiful and healthy, but to bring into operation those great institutions for developing the taste, thought, and education of the people, he felt sure that, though the ratepayers might have grumbled at first, they were now proud of what had been done. Moreover, the Mayor and Corporation had not confined themselves to general arrangements and the loan of rooms, &c., but had even granted the use of their plate and table requisites—a kindness which, though apparently slight in itself, called, he thought, for their especial gratitude. On behalf of the Society, he desired to thank also the various manufacturers in the neighbourhood who had so freely thrown open their works to the visitors. There had been no limitation whatever, the owners of the various works had trusted to their visitors, while learning lessons for themselves, taking no undue advantage of the privileges so freely accorded to them. He himself thought that very little harm was done in that way. What even technologists learnt in going over works similar to their own was not the particular little secrets which the owners relied upon for their own success. They learnt, rather, that general arrangement of plant, which, while it was useful to those who saw it, did no harm to those who arranged it. He would have felt it impossible to have accepted the position which their kindness had placed him in if the Society had been the Chemical Society. There was a time when he thought that he knew something about chemistry, but the rapid advance of the science had long left him behind. But the Society he was addressing was not the Chemical Society, and it was well that that should be borne in mind. Neither was it the Institute of Chemistry, a body which had to do with the conduct of practical analyses by skilled chemists. The body he was addressing was the Society of Chemical Industry, and members of that Society required not only chemical knowledge, but that knowledge which manufacturers gained in carrying on works and plant on a large scale. The name originally proposed was the Society of Chemical Engineers; and though the present title was preferred, it would be wise for them to try to ensure that their Council and the committees of their local Sections should always include, not only professional chemists and workers in pure science, but also men who had been successful in arranging plant and processes under the guidance of chemical knowledge. They should always seek to guard the Society from being regarded as a chemical society pure and simple. Chemists were wanted, but the chemists required the aid of manufacturers with knowledge and experience; and it was by these two classes of members working together that the Society could best serve the trade of the country. Under those circumstances, he hoped that his experience as a man of business, and his knowledge as a manufacturer, might enable him, to some extent, to justify the confidence which the members had placed in him in electing him to the high office of President. He thanked the worthy people of Nottingham, and especially the Mayor and his colleagues, for receiving the Society so kindly, and the present company for drinking the toast so heartily.

Sir JOHN TURNER, in giving the next toast, "Our Guests," said that he proposed the toast of "Our Guests" with great pleasure, and he felt that in doing so he had the sympathy and support of all the people of the town. They felt it a distinguished honour to have an opportunity of entertaining gentlemen who held so high a position in the scientific and manufacturing work of the whole world—men who had rendered immense services to science, and who had as manufacturers overcome difficulties which at one time seemed to be insuperable. Looking at the names connected with the Society,—Sir Henry Roscoe, Sir F. Abel, Walter Weldon, Dr. Perkin, David Howard, Professor Dewar, Ludwig Mond, Sir Lowthian Bell, and the new President, Mr. E. Rider Cook, any town might feel proud of having an opportunity to pay such men a compliment. If they had done anything to make the Society's visit enjoyable, they were amply repaid. He had great pleasure in coupling with the toast the names of Mr. W. E. Dobson, Mr. Councillor Fitzhugh, and Mr. Frank Lott.

Mr. J. E. DOBSON found it difficult after the able speeches of the Town Clerk and Sir John Turner to do more than reiterate their words of welcome, and to wish the members of the Society God-speed in their good work.

Councillor FITZHUGH had great pleasure in responding to the toast. He was present as President of the Nottingham and Notts Chemists' Association, an institution which was engaged in training youths whom, he hoped, would in due course become members either of the Society of Chemical Industry or of some kindred body. They had turned out many good men, and he hoped that they would make their mark in the world. It was their constant endeavour, as the Mayor and Town Clerk had said, to do everything in their power for the education of the town, and particularly, if he might say so, in his own department, which was concerned with chemical science. He would conclude by thanking the Society for the honour it had done the town by holding its meeting there on the present occasion.

Mr. FRANK LOTT, in responding, said that all the members present, with the exception of local men, were practically guests of the Nottingham Section, and the numbers present was the best proof they could have of the cordiality with which the invitation had been received. Speaking both as a member and as a guest he could only say that in whatever town the Society might next meet he hoped that they might receive as cordial a welcome and hospitality as full as that which they had enjoyed in Nottingham.

Mr. E. K. MUSPRATT, in rising to propose the toast of "The President," said that Sir Lowthian Bell had been connected with chemical industry from his infancy. His father was, he (Mr. Muspratt) believed, a partner with Mr. Losh, who had studied chemistry in Paris under the great Lavoisier. That carried one back to the birth of modern chemistry, the channel through which the great progress in industry had been brought about. Sir Lowthian Bell had been intimately connected therefore with that branch of applied chemistry with which he (Mr. Muspratt) was concerned, namely the alkali manufacture, though he had made his name by the application of chemical science to the iron manufacture of this country. He could remember the time when no iron works in England—perhaps in the world—possessed a chemical laboratory. Now, he presumed, there was not one without such an adjunct; and that in itself marked a great amount of progress. He thought, indeed, that he might justly say that all the progress made in the production of iron during the last 30 or 40 years was due to the application of chemistry. The address of the President showed what part he had taken in that application, and showed, too, that they owed a debt of gratitude to him for the position which the iron manufacture still retained in England. For with respect to that manufacture England had to a great extent been deprived of the supremacy which the contiguity of the raw materials used to give her. Other countries were now found to be as well provided and better situated than she was. But so long as England possessed men like Sir Lowthian Bell to lead the way in the application

of science to that industry, she need not fear competition with all the world. He had much pleasure therefore in proposing the toast of "The President," Sir Lowthian Bell.

Mr. DAVID HOWARD desired to express on behalf of the London Section an entire concurrence in the remarks made by Mr. Muspratt. They were proud to have as the President a man like Sir Lowthian Bell, the most eminent manufacturer of that product which, more than any other, tended to the prosperity not only of chemical industry but of all the industries of Great Britain.

The toast having been drunk with enthusiasm,

Sir LOWTHIAN BELL, in response, said that whatever might be their custom when they met together to discuss questions of a purely scientific character, they were bound, when they met round the hospitable board, to carefully abstain from debatable matter. Nevertheless, he could not allow the kind language used by his friends who had last spoken to pass unchallenged. He was sorry, on his own account, that the kind words which they had used were far in excess of his merits. He admitted that he had done a little—at any rate, he had done his best—to advance that industry with which he had been connected since his birth; but, to say that the iron industry of the world owed him a great debt of gratitude was much in excess of the truth. He was glad, on one account, to be permitted to say a few more words, and that was to express his entire concurrence in what had been said as to their reception. The machinery had worked so easily that they were apt to forget that any trouble had been encountered in making the arrangements for their entertainment. But everything had gone as smoothly as a well-balanced and carefully designed machine; and so they seemed to have been dwelling in a paradise of ease and comfort. He thanked Mr. Muspratt and Mr. Howard for their kind words in proposing his health, and the members of the Society for the cordial manner in which it had been received; and he hoped that those present would live to enjoy many more such happy meetings.

Mr. T. TYLER said that there was one more item to be brought forward, an item which the modesty of the hosts would not allow to appear on the official programme, and the charge of which had fallen upon him. He had had a great deal to do with the organisation of the meetings of the Society, but he had never felt prouder of it than he did that night. It had begun life well; it had gone on to better things; but on the present occasion it had excelled itself. To mention only a small matter—though business men would agree with him that it was on such matters that success often depended—he would refer to the fact that, following the usual precedent, a circular was issued with the last number of the Journal containing a list of the visits and entertainments, and with a request to members to initial those which they wished to attend. The highest type of bureau and the most systematic arrangement he could conceive of was the English railway booking office, where one was supplied with what he wanted with automatic precision no matter what the crowd or the pressure of business. But those who applied at University College on Wednesday morning were merely required to state their name and town, and were then immediately handed an envelope from a neatly arranged packet, containing everything that was necessary to convey them to the places they wished to visit, without trouble or price, and with the assurance of a hearty welcome. He said, therefore, that the Nottingham Section had excelled all that had been done before, and had set an example to other Sections which he hoped might be followed, but which could scarcely be surpassed. To whom did they owe all this? They owed it in part to the loyal co-operation of the Burton members of the Birmingham Section, but chiefly to the organising committee of the Nottingham Section, Sir John Turner, Professor Clowes, Mr. Archbutt, Mr. Lloyd Whiteley, Mr. S. V. Holgate, and the late Secretary, Mr. Ashwell, and to the fact that these gentlemen had secured the invaluable co-operation of the Mayor. He had the greatest pleasure, therefore, in proposing the health of the members of the

Nottingham Committee, coupled with the names of Professor Clowes, Mr. Archbutt, and Mr. Lloyd Whiteley.

The toast having been cordially drunk,

Professor CLOWES said that he had been taken by surprise by Mr. Tyrer, and scarcely knew how to thank him for his kind words respecting the Nottingham Section. It was, he thought, very fortunate that the Society of Chemical Industry ventured to "perform out of London," and did not, like a certain other Society, selfishly confine itself to the metropolis. It was an advantage to the Society at large and to the local Sections that it should be peripatetic, at least in its annual meetings. They had been profanely called "the industrious chemists," a title to which they were not likely to demur. The name certainly fitted the committee which had been working with him for months to provide entertainment for their visitors. They had been industrious, and their industry had met with its hoped-for reward.

Mr. L. ARCHBUTT wished to thank the company heartily on behalf of the Nottingham Section for the cordial manner in which their efforts had been received. There had undoubtedly been a great deal of time and labour expended; but it had been amply repaid by the success of the meeting and the numerous expressions of appreciation which had fallen from the various speakers that evening. He was only expressing the feelings of the committee when he said that they would not have succeeded as they had if it had not been for the kind co-operation of the Mayor of Nottingham and their friends of Burton. This was their first experience, and he looked forward with pleasure to the next visit of the Society after it had gone the round of the other Sections.

In the intervals between the toasts a selection of songs and instrumental pieces was admirably rendered by Madame Fannie Lynn, Mr. Bingley Shaw, Mr. Charles Young, Mr. Alfred R. Watson, and a select band under the direction of the latter gentleman.

### THIRD DAY.

On Friday morning a party of about 140 members left the Great Northern station at Nottingham, at 8.30, by special train for Worksop. The weather was, unfortunately, cold, damp, and gloomy, but little rain actually fell. This was of some importance, as at Worksop some dozen or more open breaks met the party—half of whom proceeded to Welbeck Abbey, the seat of the Duke of Portland, and the remainder to Clumber, the seat of the Duke of Newcastle. Both parties then proceeded to Edwinstowe, where an excellent lunch was provided by the Section. After lunch the Welbeck party returned *via* Clumber, and the Clumber party *via* Welbeck, reaching Worksop at 6 o'clock and Nottingham at half-past eight, after a very enjoyable day.

## London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

*Chairman:* T. Tyrer.

*Committee:*

W. Crowder.	B. E. R. Newlands.
J. Dewar.	B. Redwood.
A. G. Green.	John Spiller.
S. Hall.	W. S. Squire.
C. W. Heaton.	Wm. Thorp.
D. Howard.	T. E. Thorpe.
C. C. Hutchinson.	C. R. Alder Wright.
R. Messel.	

*Hon. Local Sec. and Treasurer:*

T. W. B. Mumford, 1, Glendale Villas, Sylvan Road, Wanstead, E.

### ON THE ACCURACY OF THE GREASE SPOT PHOTOMETER FOR MEASURING THE DENSITY OF PHOTOGRAPHIC PLATES, AND A NOTE ON THE SECTOR PHOTOMETER.

BY CAPTAIN W. M. W. ABNEY, C.B., R.E., D.C.L., F.R.S.

THE publication of a paper by Messrs. Hurter and Driffield in the Journal of Chemical Industry, on "Photo-Chemical Investigation, and a New Method of Determination of the Sensitiveness of Photographic Plates" has induced me to offer a few criticisms on the subject.

I have two reasons for doing this; one is that I have written a good deal regarding part of it, and the other that some doubt is thrown in the paper on the accuracy of the results I have obtained, owing, as it is asserted, to the photometer I use being faulty.

I should have been unwilling to enter into a criticism of the paper now the session is over were it not that it will no doubt be quoted largely at home and abroad as giving an authoritative exposition of the law of density, and that no opportunity of having a say in the matter would occur before November.

We may take the paper as practically divided into four parts: Definitions of terms employed; instrument for measuring and method of measuring the density of deposit in photographic plates; methods of producing density; and a mathematical investigation of the subject.

Under the first heading I may have one or two criticisms to make subsequently—such as on the law of absorption applied to a film in which opaque particles are embedded—but for the present I wish to confine myself to the second division, viz., the instrument and the mode of measuring densities, for if these are in fault, the measured densities and the application of theory to them will require revision.

To begin with, the instrument itself as used by the authors. There is a statement made regarding the method of photometry employed to which I must take exception, and that is that the Bunsen disc is more sensitive than the (Rumford) method of shadows. The leading authorities on photometry in London, viz., the Gas Referees, have adopted the shadow test, and certainly the measurements made by Mr. Vernon Harecourt are not wanting in delicacy. The well-known drawback to the grease spot method is the necessity of excluding all reflected light from the grease spot, and when it is recollected that the blackest lamp-black reflects more than 2 per cent. of white light, the exclusion of all such reflected light becomes a problem very hard to solve, more especially in an instrument  $12 \times 4 \times 6$  in. such as is used by Messrs. Hurter and Driffield. I am not saying that they have not overcome this difficulty, but I bring forward a possible objection to this instrument. This may be passed over, however; but unless I am very much mistaken a much more serious, if not fatal, objection must be taken to it when measuring the density of photographic deposits, and is one I have long been practically acquainted with, and which I have again investigated recently. Let any one, after focussing a view, replace the ground glass of a camera by a photographic negative, and place his head under the focussing cloth. He will see two objects, the lens through the plate, and the view, more or less dim, on the negative itself. In other words, the film acts like ground glass and is partially translucent. Now if the negative be replaced by a glass of apparently the same darkness in which the colouring matter is part of the glass itself, the view is no longer visible, or, if visible at all, very faintly so, but the lens will be clearly seen. Now ground glass, if illuminated, becomes practically a source of light, the light being scattered in every direction, but it naturally illuminates more strongly in the direction from which the original light falls on it, if the glass be perpendicular to that direction. Thus, when a piece of ground glass is placed at the end of a narrow tube which is inserted in the walls of a dark, and black

painted, room (the ground surface being inside the room), it will be found that if a beam of light be sent through the tube, not only is the room illuminated exactly opposite the tube, as it would be were the ground glass removed, but also at every angle with the axis of the tube. The illumination of a white surface gave the following results in one case, the surface being always at the same distance from the aperture.

TABLE I.

Angle from the Axis.	Relative Illumination.
0°	100
10	64
20	21
30	14
40	8.2
50	7.2
60	6.0

Evidently the amount of scattered light would here have to be taken into account, as, if not, it would be immaterial if the ground glass were in front of the tube or not, except for the small amount of light which would be reflected back towards the source of light; and further, the brightness of the light which illuminated the grease spot would not vary exactly inversely as the square of the distance since the light is not symmetrically scattered, if we may use such a phrase.

If the ground glass in the above experiment be replaced by a piece of a negative the same scattering of light will be readily seen by holding a piece of white card about 1 ft. from the orifice.

Now let us see how the results obtained by the instrument under consideration would be affected by the "ground glass" effect of the negative. Suppose we have two lights properly enclosed in a darkened room, one stationary with an aperture in front of it, the flame being of such dimensions that it more than fills the aperture (in fact, just as the authors arrange both their lights) and the other moveable. Let a moveable Bunsen disc be placed at some fixed distance from the aperture, and the other light be moved till equality of illumination of the grease spot is secured, and let the distances of the aperture and of the moveable light from the grease spot be noted. Next, let the Bunsen disc be moved to a different distance from the aperture and the moveable light be again moved till equality of illumination is secured, and let the two distances be again measured. The distances of the aperture and of the moveable light from the grease spot in the first case should be proportional to the two distances in the second case. Suppose, in the first instance, the distance of the aperture from the grease spot was 6 in. and that of the moveable light 3 ft., then if the grease spot be moved to 12 in. from the aperture the distance of the moveable light should be 6 ft., and so on. Now if the measurement of density of a plate by the grease spot method be correct when a film is placed in contact with the aperture, the same should hold good, but if the scattering of light by the film affects the result it should not. To test this I have made a good many very careful experiments, and I cite one here, which is a sample of the results obtained in all cases. The plan adopted was to make measures of a lighted aperture as stated, and then without any alteration of the general arrangement to place a portion of a plate with a photographic deposit upon it against the aperture, and measure the light coming through it by placing the grease spot at different distances from the aperture, and then to get equality of grease spot illumination by moving the second light. Table II. gives the measures of the unmasked aperture, which was about  $\frac{1}{4}$  in. in diameter as taken.

TABLE II.

Distances of Aperture from Grease Spot.	Distance of Moveable Light from Grease Spot.		
	Readings.	Mean.	Adopted.
Cm. 3.5	1.3, 75, 1.2	4	4
7	8, 8, 8,	8	8
14	16, 16	16	16
28	31½, 31½, 32	31.7	32
42	47½, 48½, 48½	48.2	48
56	63, 63, 63	63.3	64
70	80, 78, 79, 79	79	80

The readings are sufficiently close to show that for naked lights the results are concordant. Table III. gives the measures of the light passing through a negative, and at different distances reaching the grease spot.

TABLE III.

Distance of Aperture from Grease Spot Negative in Front.	Distance of Moveable Light from Grease Spot.			Ratio of Distance of Aperture to Moveable Light from Grease Spot.
	Readings.	Mean.	Adopted.	
Cm. 3	42½, 42, 42½	42.7	42.7	14.2
4	48, 49, 49	48.7	48.7	12.2
5	57, 58, 56½	57.2	57.2	11.4
6	63, 62, 64	63	63	10.5
8	84, 85, 84	84.3	84.3	10.5
9	93, 95, 95	93.7	93.7	10.4
10	102, 99, 100	100.3	100.3	10.03

If we critically examine this table we shall at once notice that large discrepancies appear. For instance, at 6 in the first 1st column, the distance of the moveable lamp should be double that at 3, or should be 85.4, but it is only 63; so at 8, if it were double of that at 4, it should be 97.4, whereas it is 84.3; at 10 it should double that at 5, or 114.4, whereas it is 100.3. The last column gives the ratios of the distances.

The squares of the ratios of the first and last measures, viz., at 3 and 10, the distances of the aperture from the source, are as 201.6 to 100.6, or nearly as 2 to 1. The nearer distance of the screen to the aperture therefore gives a lower value of the transmitted light than the further one. The question is which is, if either is, correct, and looking at it from a theoretical point of view, it appears that neither is. According to these two measures the light transmitted through the negative was about  $\frac{1}{1.5}$ th and  $\frac{1}{2.5}$ th, whereas by a correct means of measurement the amount transmitted was found close upon  $\frac{1}{1.5}$ th.

The trial of their instrument by the authors with Indian ink and indigo solutions is totally different to its trial with films. In a minor degree Indian ink scatters, but the indigo solution is transparent. Now, from the published description\* of the instrument as used by Messrs. Hurter

\* A rough description of their instrument is as follows:—A box 12 in. x 6 in. x 4 in. with an aperture of small dimensions at each end. A broad light behind each aperture so that all distances to the disc carrying the grease spot can be measured from the apertures. The grease spot disc is in a box two inches cube, travelling inside the bigger tube, apertures being cut to allow the light to pass. In front of one aperture the negative whose density has to be measured is placed, and equality of illumination is secured by cutting off light from the other aperture and by moving the grease-spot disc.

and Driffield it is probably impossible for the grease spot to be nearer to the aperture than  $1\frac{1}{2}$  in., or about 3 cm., seeing that the inner box is 2 in. cube, and that we have to add for the thickness of the glass of the negative and the thickness of the box itself. We may take it that the distance of the grease spot in the measures made varies between 6 in. and  $1\frac{1}{2}$  (15 and 3 cm.) inches, and in this range there can be a remarkable variation of densities to be obtained from the different readings. It may be said that the measures obtained are concordant one with another. This may be so, since it will be seen from Table III. that after a certain range is passed the ratios of the two distances become almost the same, but they will not be true measures of the light transmitted. Taking all things into account, it seems not unreasonable to conclude that the measures of light given as transmitted through deposits are too small; and as has been shown, when the densities are great, and the grease spot has to be moved close to the aperture, the variation may be as much as 100 per cent. less than would have been obtained if a longer box had been employed and the disc were further from the aperture.

In this part of the paper to which I am confining myself, the authors allude to the photometer which I use, and which works on the principle of cutting off light by means of rotating sectors of varying apertures, but a remark is made which more than suggests a want of accuracy in its measure. The authors say that with it the density measured "rises to over 100 per cent. (of error) with plates of high densities, which renders it utterly untrustworthy." From the formula of light transmitted through my photometer given by the authors the 100 per cent. evidently means making the density too great. In taking exception to the results obtained by their grease spot method, I have indicated experiments which anyone interested can try, and I shall now give some made with my own photometer. I might, however, stop here and use an "*argumentum ad hominem*" which would be thus. The grease spot photometer having been proved capable of giving results *inter se* 100 per cent. in error, and mine having in the same hands given results 100 per cent. in error when compared with these, may it not be assumed that my photometer gives correct results, or at all events more nearly correct results than the grease spot method gives? Setting this kind of argument on one side I will for a brief space examine the statements that have been made regarding my photometer. They say the light transmitted is more correctly represented by  $I_x = I \cdot \frac{\phi}{360} + C$

(where  $I_x$  is the light transmitted,  $I$  the light falling on the sector,  $\phi$  the aperture of the sectors, and  $C$  a constant), than by  $I_x = I \cdot \frac{\phi}{360}$ , which I have always taken as the true transmission. Their formula of course, if pushed to extremes, results in an absurdity, for if the aperture be  $0^\circ$ , that is if the sectors be closed, still  $C$  light will be transmitted. The reason assigned for adopting this formula is said to "be due to the semi-shadow on both edges of the sector openings." Evidently then, if we increase the number of sector openings, keeping the total aperture the same, the magnitude of  $C$  will increase. If with 2 sectors it is  $C$  then with 4 sectors it would be  $2C$ , with 8 sectors  $4C$ , and so on, till we arrive at a point when  $nC = I$ , which is the total intensity, leaving no light to pass through the apertures.

Had the formula been  $I_x = (I \cdot \frac{\phi}{360} - C)$  there might have been something to say in its favour, for if the light be close to the sectors the thickness of the metal of which the sectors are made might possibly cut off a fraction of a degree, but but as I never use the photometer in such a manner any error caused by this is quite negligible, more especially as the photometer, for other reasons, is rarely read below  $7^\circ$  or  $8^\circ$ , the light being adjusted to make higher readings when low readings with one position of light would be obtained.

I may as well here give some experimental results of the correctness of the photometer.

Two incandescence lights approximately similar in dimensions were used and kept glowing with a constant current. One lamp was fixed at a distance of about 18 inches from the screen, and the other placed on a block sliding on a bar,

and the illuminated shadows cast by a rod fell on a white patch and were equalised in brightness. The rotating sectors were introduced between the first light and the screen and were fixed at different apertures. Equality of illumination was obtained by sliding one light along the bar.

The following are the results:—

TABLE IV.

Sectors set at	Mean Reading of the Distance of the Movable Lamp.	Calculated Value.
°		°
180	16.25	180
90	23	90
45	32	46.5
20.5	48.5	20.2
10	69	10
4.8	101	4.7

In the next two tables we have a large luminous source, viz., an Argand burner  $\frac{3}{4}$  in. in diameter.

The first shows the worst measures made, and the second, one usually obtained.

TABLE V.

Sector Set at	Mean Readings of Lamp from Source.	Calculated Intensity.
°		
180	13.75	176.8
88	19.5	88
60	23.5	60.5
45	27.25	44.5
30	33	30.8
10	59	9.6
5	83	4.8

TABLE VI.

Sector Set at	Mean Reading of Lamp from Source.	Calculated Intensity.
°		
180	13.25	180
90	18.75	90.3
44.5	24.75	44.6
10	57.25	9.6
5.2	79.0	5.1
3	106.5	2.8

Equally good results were obtained when the sectors were placed in the beam of light which was focussed on the screen by means of a lens.

In the foregoing remarks I have given my criticisms on the accuracy of the grease spot photometer for measuring densities, and it has seemed to me that the whole paper more or less hangs on this. I have also endeavoured to vindicate the sector photometer from the slur which has been placed upon it. All the experiments I have given on both subjects are easy to repeat, and I trust that some independent physicist will take the matter up, and judge between myself and the authors.

It would be premature to go into the proofs which can be adduced that the method employed by myself for measuring the densities is correct. If necessary, such proof can be given. Doubt has only been thrown upon the instrument I use, and not on the manner of using it in its latest development. My admiration of the paper is not diminished by any fault I have found in the methods employed by Messrs Hurter and Driffield, but I thought it right, in the interests of photographic science, to point out what I believe to be a weak spot in the proofs of their theory.

## REPLY TO THE PRECEDING COMMUNICATION OF CAPTAIN ABNEY "ON THE ACCURACY OF THE GREASE SPOT PHOTOMETER, Etc.\*"

BY FERDINAND HURTER, F.R.S., AND V. C. DRIFFIELD.

CAPTAIN ABNEY has conferred a great honour upon us by his kind criticism of part of our paper.

The objections which Captain Abney brings against our photometer are two. In the first place he objects to the light reflected from the walls of the blackened large chamber as likely to interfere with the readings of our instrument. But we placed the photometer disc within a second chamber for this very reason, and the light reflected from the walls of the second chamber are equal on both sides when the disc is at point of equality.

The second objection is of greater importance. The phenomenon of "scattering" represents one of the great difficulties to contend with. It is more readily observed with white opaque substances, such as ground glass or emulsions, but it also undoubtedly exists, though to a small extent, in negatives. Fortunately, it interferes only in plates of very high densities.

The experimental results given by Captain Abney agree fairly with our own, though they are rather worse. We have, however, guarded against serious errors by showing in Table I. the extreme limits to which we use the instrument. It will there be seen that the last figure we use is 1.7, corresponding to  $l \times 0.75$ , which in our instrument means a distance of 1.5 inches between the Bunsen disc and the plate to be measured. If we accept Captain Abney's results, given in Table III., as correct, the relative densities shown for this distance of 4 cm., and one of 10 cm., would be proportional to the logarithms of the numbers 12.2 and 10.03 respectively, i.e., to 1.086 and 1.00, and the error made in this extreme case would be 8 per cent. only, and not 100 per cent., as stated by Captain Abney. But it is very seldom indeed that the disc has to be moved so close to the plate as is assumed in this example, and we have clearly and carefully stated that we do not claim any greater accuracy than 5 per cent.

With regard to the angle subtended by the spot of the Bunsen disc and the diameter of the diaphragm, it is even in this extreme case less than  $10^\circ$ .

Respecting the objection we made to the revolving sector, we asserted that the light transmitted by the sector was not exactly the half or the quarter of that which the lamp gives directly, when the sector is open to  $180^\circ$  and to  $90^\circ$  respectively, and the experiments quoted by Captain Abney are no answer to this objection. We also stated that the error was small with plates of low density. The formula we gave was the result of experiment and not of any theoretical considerations.

Like other empirical formulæ it has the property of leading to absurdities when pushed to extremes. We may have occasion to quote an important formula published by

Captain Abney which has the same disagreeable property, but it is interesting perhaps to state that we assured ourselves of the existence of the error by the very experiment Captain Abney mentions, viz., by multiplying the sector openings.

We have to apologise to Captain Abney for the omission in our paper of an important statement which was made when the paper was read, viz., that this error does not in any way affect the results of his researches on the sensitiveness of the silver compounds to the various parts of the spectrum. We thank Captain Abney for his expression of admiration of our paper, and we can assure him that we do not undervalue or wish to detract from the importance of his classical researches.

## Journal and Patent\* Literature.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

*Tannin Matters as Anti-incrustators for Steam Boilers.*

L. Vignon. Bull. Soc. Chim. 1890, 3, 410—413.

See under XXIII., page 767.

#### PATENTS.

*Improvements in or relating to Glass-lined Fittings for Glass-lined Tubing.* D. Rylands, J. Crowder, and R. Morant, Barnsley. Eng. Pat. 6750, April 20, 1889. 8d.

This specification describes the operation of lining pipe fittings with glass and gives examples of lining "tees" and elbows. A "tee" is lined by introducing a piece of tubing through the head and suitably holding it while a hole is made in the side in the ordinary way, by means of a blow-pipe flame through the side piece. Another piece of glass tube may then be welded on. The space between the glass tee and the metal tee is packed with pitch, cement, &c. Modifications are described.—O. H.

*Improvements in and connected with Filters for Water and other Liquors.* R. Bruce, C. C. M. Gibson, and E. D. Reeve, London. Eng. Pat. 8265, May 17, 1889. 1s. 3d.

THE inventors make their filter in the shape of a porous tubular vessel, closed at both ends, which they insert either vertically or horizontally in a tank containing the water to be filtered. One end is closed with a cap, the other screwed to a plate which has a central exit passage through which the filtered water is carried away, passing through the side or bottom of the tank by means of a stuffing-box. The plate on which the filtering tube is secured can be made to rotate on its central outlet for the purpose of allowing the outer face of the tube to be cleaned either by a jet of water or steam, or in any other manner. Several filtering tubes may be set on to one rotating plate, and such an arrange-

\* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Luck, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d. ....	3d.
Above 8d., and not exceeding 1s. 6d. ....	1d.
" 1s. 6d., " " 2s. 4d. ....	1½d.
" 2s. 4d., " " 3s. 4d. ....	2d.

\* These communications, though strictly not within the scope of the Journal of the Society, have been inserted on account of the interest of the subject, but in accordance with a resolution of the Publication Committee, no communications of a controversial nature, apart from reports of discussions of papers in open meetings of the Sections of the Society, will in future be inserted.—ED.

ment, with horizontal tubes, is shown in section in the accompanying illustration.

FILTER FOR WATER OR OTHER LIQUID.

In this arrangement of the apparatus, if the rotating gear be temporarily stopped and the water in the tank lowered below the level of the upper tube or tubes, these can be removed, cleaned, and replaced without arresting the action of the other tubes. Six sheets of drawings are attached to the specification, and there are 13 claims.—B.

*Apparatus for the Methodical and Continuous Treatment of Pulverulent Matters by Fluids.* W. L. Wise, London. From Solvay and Co., Brussels, Belgium. Eng. Pat. 8872, May 28, 1889. 8d.

THE treatment of solids by gases has always presented difficulties when the gases pass in from below upwards.

TREATMENT OF PULVERULENT MATTERS BY GASES, &c.

Channels are apt to be formed through which the main body of the current of gas passes, there being thus an excess in the one place and a deficiency in the other. Consequently numerous efforts have been made to overcome these disadvantages by causing the gas to travel in the opposite direction, *i.e.*, from above downwards. Any channels are now kept closed by the action of gravity and by the current of gas itself, the whole reaction being thus uniform. In this invention the vessel A is cupola-shaped, and carried upon hollow trunnions. The gas enters at D, passing downwards through A and issuing at D¹. When the reaction in the upper layer or layers is completed the cupola is turned through half a revolution and a given amount allowed to fall out through C¹, which of course is now lowermost, a fresh charge being introduced at C. If necessary to avoid shaking the material in the vessel A when discharging, a false bottom may be introduced and worked from outside, as shown at E. The apparatus is turned back to its old position and the operation begins again *de novo*. The charges therefore work by gradual stages through the cupola.—S. G. R.

*Improvements in Apparatus for Treating Metallic Ores or Compounds with Chemicals.* S. Alley, Polmadie. Eng. Pat. 9592, June 11, 1889. 8d.

THIS apparatus consists of a metallic vessel coated inside and out with vulcanised rubber and capable of being rotated on hollow trunnions. At one end is a valve opening inwards, kept closed by means of the elasticity of rubber rings placed on its spindle. The valve coincides above with a hopper for charging, and below with a vessel provided with a filtering bed, into which the contents of the cylinder are discharged. The vessel is provided with a flexible cover of rubber. The cover has a ring-shaped opening in its centre, which can be pressed in contact with the above-mentioned valve, thereby forming an air-tight joint when discharging.—H. K. T.

*New or Improved Method of Distilling Products by Means of Steam, and Classifying or Separating them according to their respective Points of Vaporisation, and Apparatus therefor.* W. P. Thompson, Liverpool. From N. Notkin, Moscow, Russia, and P. Marix, Paris, France. Eng. Pat. 10,907, July 6, 1889. 6d.

THE method of distillation recommended in this patent could not well be made clear without transcribing the specification in full, to which readers are referred. There are no drawings attached to illustrate the arrangement of the apparatus, and the claims recorded are the following, *viz.*:—“(1.) A process of continuous distillation and classification of distilled products by means of steam used (a) indirectly (*viz.*, without mixing it) to carry those to a temperature near the point of vaporisation of the more volatile parts, and then (b) directly by acting successively on small parts at a time to produce distillation and classification of the products that distil, substantially as described.

“(2.) In the above process of continuous distillation and classification of products, the special manner or method whereby the steam acts by a direct way consisting in mixing the steam and substance in stills separated from the supply vat, and thus by proceeding either by pulverisation (single or repeated), or by single or repeated steam clearing and at temperatures conveniently increasing from one still to the other, to obtain the classification of the distillation substantially as described.”—B.

*Improvements in Filtering Apparatus.* H. J. E. Jensen and E. F. G. Busch, Hamburg, Germany. Eng. Pat. 10,921, July 6, 1889. 8d.

THE improvements contemplated are more particularly applicable to filters constructed under a previous patent, Eng. Pat. 5669 of 1886 (this Journal, 1887, 364). They refer to details of construction and to methods of cleaning of that class of filters which is composed of a number of hollow porous drums or discs secured to a hollow rotating

shaft and inserted in a tank containing the unfiltered liquid, the drums acting as filters and the shaft serving to conduct the filtered liquid away.

The improvements consist in perforated tubes which are fitted between adjacent drums, and admit of streams of water impinging against the surfaces of the rotating drums at acute angles, for the purpose of carrying away the accumulated impurities. Or rotary brushes through the circumferences of which currents of water are issuing are fitted into the spaces between the drums with the same object in view. There are two sheets of drawings and 10 claims.—B.

*Improvements in Apparatus for Evaporating, Heating, or Cooling Liquids.* R. C. Garton, C. H. Garton, and W. Lawrence, London. Eng. Pat. 11,350, July 15, 1889. 8d.

THE invention relates to apparatus in which the process is carried on under ordinary atmospheric pressure. Vertical (or nearly vertical) tubes made of any suitable material are fluted, grooved, twisted, or otherwise formed so as to increase their external and internal surfaces. The diameter of the tubes, and the angles at which they are twisted, depend upon the nature of the liquid to be acted upon. Steam is admitted to one side of the tube, either externally or internally, as desired, and the liquid to be treated flows down the reverse side in a thin film; or by jacketing the tubes a double effect can be obtained. The invention is stated to be of "special utility in the evaporation of already partly concentrated liquors in chemical and other manufactures when great rapidity of concentration is desirable in the finishing process, and particularly in the evaporation of viscous substances, and the crystallisation of salts."—E. S.

*Improvements in the Crystallisation of Salts or Crystallisable Acids.* R. C. Garton, C. H. Garton, and W. Lawrence, London. Eng. Pat. 11,351, July 15, 1889. 8d.

SOLUTIONS are usually crystallised in open pans. The crystals formed are found at the bottom, and thus impede the evaporation of the rest of the solution. Further boiling is apt to decompose and alter the constitution of the crystals already produced. The patentees use tubes grooved either longitudinally, spirally, or laterally, and heated by hot air, steam, &c. The liquid to be concentrated may either be caused to flow on the outside or inside of the tubes, the heating agent passing along the opposite side, jacketing being employed if necessary. The grooves may run spirally round the tubes, and are cut of different pitches. With a very viscous solution the grooves may be made at an angle of 45°, in other cases at a slower pitch. The diameter of the tubes may vary, from 1½ to 5 in. being recommended both for inside and outside flow, but in the former case the indentations should be deeper. The tubes may be made of metal, glass, porcelain, earthenware, or of other materials. (See preceding abstract.)—S. G. R.

*Apparatus for Purifying Water for Economisers.* G. W. Allen and H. J. A. Bowers, Manchester. Eng. Pat. 11,595, July 20, 1889. 6d.

THIS invention consists chiefly in improvements in Eng. Pat. 7772 of 1887 (this Journal, 1888, 313) so as to apply the same advantageously to an economiser. For this purpose, "collectors" are used instead of the "scum plate" described in the former patent. These are placed in the bottom boxes of the economiser to collect the impurities deposited by the feed water. Each collector is preferably a slotted casting of an inverted V shape in cross section, and communicates, by means of a flow-pipe, with an external "separator." The return pipe from the separator is connected to the bottom boxes of the economiser, and terminates in a nozzle on the injector principle in order to ensure the circulation of water in the proper direction.—E. S.

*Improvements in and connected with Apparatus for Drying Granular and like Materials.* S. Seckendorf, London. From M. Reuland, Dortmund, Germany. Eng. Pat. 3089, February 26, 1890. 8d.

"THE object of this invention is an apparatus for drying granular, pasty, or thick material, in which the drying material is gradually moved over an inclined heated surface by means of obliquely placed scrapers, whence it passes into troughs or additional drying receptacles." For the mode by which this is effected, the specification and the drawings accompanying it must be consulted. There are six claims.—E. S.

*Improvements in Apparatus for Purifying and Cooling Water.* G. Simpson, Philadelphia, U.S.A. Eng. Pat. 4251, March 18, 1890. 6d.

THE apparatus consists of a tank having two partitions, one forming a chamber for receiving the water, and the other a storage vessel for the purified water, the two being separated by a cold well, which communicates with an ice chamber in the upper part of the storage vessel. Outside the tank is a coil supplied with water through a pipe, and controlled by a regulating valve in the tank, the water being heated by a gas jet beneath the coil, and afterwards flowing into the tank, from which it passes through the filtering bottom of the storage vessel to the ice chamber. There are five claims.—E. S.

*Improvements in Kilns for Cement and the like.* W. A. Gibbs, Chingford. Eng. Pat. 4741, March 26, 1890. 8d.

THE inventor proposes to apply a water jacket to kilns for drying and burning cement, &c., for the purpose of heating water or raising steam.

The water jacket may either be a casting or consist of steel or iron plates, or of a solid welded coil of pipe, or of a series of vertical pipes united by junction chambers at the top and bottom. A portion of the steam obtained in this way may be used to increase the heat within the kiln by producing a forced draught of air or of air impregnated with petroleum vapour through the cement, this blast being optionally heated in a regenerator by means of the waste gases.

The waste gases are utilised for drying the cement slurry on the ground level so as to obviate the necessity for pumping it up to the top of the kiln. For this purpose, the fire is lighted at the top of the kiln, and the heated gases drawn down by a fan, and either passed into metal tubes with shallow trays containing the slurry on their upper sides, or blown over the surface of the slurry contained in shallow tunnels. It is claimed that the substitution of water jackets for the interior brick lining of cement kilns greatly reduces the cost of repairs.—S. B. A. A.

*Improvements in the Construction and Working of Double, Triple, and Multiple Effect Evaporating Apparatus.* A. Chapman and S. Vickess, jun., Liverpool. Eng. Pat. 5267, April 5, 1890. 6d.

THE improvement consists in causing the liquid to be evaporated, to flow from the pan or pans of lower pressure to those of higher pressure, and the steam or vapour to go from pans containing liquid of greater density to those having liquid of lower density. By this arrangement liquid can be concentrated to greater density than in the ordinary manner of carrying out the process. The drawing attached to the specification shows the apparatus as arranged for producing a quadruple effect. The pans shown are of the ordinary construction, but those described in Eng. Pat. 1752 of 1888 (this Journal, 1889, 128) may also be used.—E. S.

*Improvements in the Evaporation of Brine and other Solutions or Liquids, and in Apparatus employed therein.* J. C. Mewburn, London. From C. C. Peek, Warsaw, U.S.A. Eng. Pat. 6107, April 22, 1890. 1s. 1d.

THE invention is intended, primarily, for the evaporation of brine in the manufacture of salt, but it can be applied to other liquids. The principal improvements consist (1) in the position of the heating surface, (2) in the construction of the vacuum chamber, (3) in making the process continuous, (4) in heating the brine before introducing it into the vacuum chamber, and in effecting its proper circulation. For details of construction and the mode of working, the specification and eight sheets of drawings must be consulted. There are 26 claims.—E. S.

*New or Improved Preparation or Composition for Dissolving Boiler Scale, and for Preventing Formation of such Scale.* J. Effrem, Berlin, Germany. Eng. Pat. 6478, April 28, 1890. 4d.

THE composition consists of the following substances in or about the proportions mentioned, viz.:—25 parts by weight of potato starch, 25 of concentrated lye, 3 of leather glue, 47 of water.—A. J. K.

#### ERRATUM.

The larger figure at foot of page 594 is made continuous, whereas the horizontal lines should have been broken  $2\frac{1}{2}$  inches from right-hand side of figure. An erasure in a vertical line, or a strip of paper  $\frac{1}{4}$  inch wide pasted across the figure at the part indicated will produce the effect intended.

## II.—FUEL, GAS, AND LIGHT.

*Determination of Ferrocyanide in the Residues from Gas Purifiers.* R. Zoloziecki. Zeits. f. angew. Chem. 1890, 301—302.

See under XXIII., page 767.

#### PATENTS.

*Improvements in Artificial Fuel.* A. Myall, London. From J. H. Lancaster, New York, U.S.A. Eng. Pat. 8040, May 14, 1889. 6d.

"SEXTALIT" is claimed as a new fuel for domestic heating purposes, and it is alleged that it may be burnt in flueless stoves without "emitting any smoke, or noxious gases or vapours." It is prepared as follows:—

100 lb. of finely divided charcoal are re-calcined to expel all the contained gases or vapours, mixed with  $1\frac{1}{2}$  lb. of manganese dioxide, and with a solution of  $3\frac{1}{2}$  lb. of starch and  $3\frac{1}{2}$  lb. of saltpetre, moulded into blocks, &c., and dried at a gentle heat. Coke or other carbonaceous substance may be substituted for charcoal, and "acetate of lead" for the manganese peroxide.—S. B. A. A.

*Improved Burner for Alcohol, Petroleum and other Combustible Liquids.* E. H. Allain, Créteil (Seine), France. Eng. Pat. 8304, May 18, 1889. 11d.

THE heating apparatus fitted with the improved burner consists essentially of a vessel containing a central asbestos wick of "tubular form" surrounded by a layer of an absorbent incombustible substance susceptible of being heated, such as sand, asbestos or "vegetable earth." A thick wire may then be coiled around in a spiral form, and the remainder of the vessel filled with some absorbent substance which conducts heat badly. The wick is immovable and does not project beyond the top of the vessel, and both the top and bottom of the vessel are perforated concentrically with the wick; only the interior surface of the wick is thus exposed, and accordingly combustion takes place on that surface alone. To regulate or extinguish the flame a lever is arranged to raise or

lower a metallic tube moveable in the central perforation of the vessel, thus masking the interior surface of the wick to any extent required. Devices are also shown for distributing the fuel and for preventing its evaporation when the apparatus is not in use. Two modifications are given; in one of these, which is adapted for illuminating purposes, the burner consists of the small central tube, asbestos wick, and one absorbent layer, the latter being connected by a capillary feed wick with a reservoir of the combustible liquid placed beneath.—S. B. A. A.

*Improvements in Furnaces and Grates therefor, and Means for conducting Air thereto.* S. J. Miles, Chicago, U.S.A. Eng. Pat. 255, January 7, 1890. 6d.

THE furnace and appliances are designed especially for burning coal slack and other fine refuse. The combustion chamber is divided into compartments by transverse bridge walls rising to some distance above the level of the grates, there are also transverse curtain walls which hang down from the roof over the centre of each chamber (except the first) for some distance below the level of the tops of the bridge walls. The grate bars are perforated, and each compartment of the combustion chamber is provided with a practically air-tight ash pit into which a blast of air is supplied from a pipe communicating with a fan. Refuse fuel is charged on the first perforated grate and there in great part uniformly consumed; a portion is, however, forced by the blast over the bridge wall into the next compartment, there arrested by the curtain wall and deflected on to the second grate, from which likewise a portion is blown over to the next grate, and so on. An arrangement is also described for cleaning the ash pits.—S. B. A. A.

## III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Researches on the most Volatile Constituents of Coal Tar.* J. Biehringer. Dingl. Polyt. J. 276, 78—90 and 184—191.

IN their investigations of the most volatile portions of coal tar, authors have hitherto employed the first runnings obtained by the distillation of benzene hydrocarbons which have been subjected to a preliminary treatment with acids and alkalis. On this account a number of substances present in the crude material have escaped identification owing to their removal by this treatment, whilst new bodies formed by the action of acids and alkalis have been isolated which could not be detected in the raw material, and it is doubtlessly owing to this circumstance that conflicting statements have been published regarding the presence or absence of a number of substances in the most volatile portions of coal tar. The author therefore thought it desirable to employ unrefined benzene hydrocarbons for the purpose of this investigation, special attention being also given to the quantitative determination of the more important constituents by simple and accurate methods. At first the portion of English 90 per cent. benzene boiling between  $30^{\circ}$  and  $80^{\circ}$  was used, of which about 1.5 per cent. was obtained. Subsequently the fractions boiling between  $50^{\circ}$ — $60^{\circ}$  and  $60^{\circ}$ — $70^{\circ}$  were chosen, the necessary material being obtained from Dr. Häussermann of the Griessheim Chemical Works, and the fractions being marked L1 and L2 respectively. They form colourless mobile strongly refractive liquids (assuming a yellow colour on standing), and possess a disagreeable penetrating odour which causes headache and slight giddiness after prolonged inhalation. The taste is caustic. Blue litmus paper is turned red. They burn with a luminous smoky flame which gives off a disagreeable odour. All attempts to isolate the different constituents by fractional distillation were unsuccessful; thus the fraction L1 which gave about 66 per cent. between  $50^{\circ}$  and  $60^{\circ}$  began to boil at  $40^{\circ}$ , and left a considerable residue boiling above  $60^{\circ}$ , and although after several fractionations it was possible to gradually concentrate the carbon disulphide in the portion boiling below  $50^{\circ}$ , the

results were by no means satisfactory, as this end could only be achieved at the expense of the higher boiling portion. It would, in fact, seem as if it were not merely some peculiar property brought about by the process of fractional distillation which gives rise to this anomaly, but as if during the distillation the mixture suffered decomposition, forming new substances which considerably influence the boiling point. The author therefore tried the following methods:—He attempted to remove by some means the bodies known to be present and then searched for new substances, and in a second series of experiments he made a number of tests to detect the presence or absence of certain hydrocarbon series by means of well-known group reagents.

1. *Carbon disulphide* was first obtained by Vincent and Delachanal from the low boiling portions of unrefined benzene. Its presence completely masks the results obtained by fractional distillation, and as acids and alkalis fail to remove it commercial benzenes are almost invariably contaminated therewith. For the quantitative determination Hofmann's process was tried. This is based on the formation of a well crystallised red additive compound when carbon disulphide is brought in contact with triethylphosphine. The author used pure carbon disulphide boiling at  $46.8^{\circ}$ , but failed to obtain satisfactory results although he is unable to explain the cause of this. The numbers were invariably too low. He then tried the xanthic acid reaction. For this purpose a measured quantity of carbon disulphide or liquid containing the latter is added gradually to an alcoholic solution of potash, when potassium xanthate is formed. The amount of the latter is then estimated as cupric xanthate by adding a decinormal solution of cupric sulphate until there is a slight excess of the copper salt which is ascertained by placing a drop of the solution from time to time on a double filter paper and testing the liquid on the lower paper with potassium ferrocyanide. One cc. of the copper solution is equal to 0.0152 gm. of  $\text{CS}_2$ . The method gives good results. The following numbers were obtained:—

	Per Cent. $\text{CS}_2$
Fraction boiling between $36^{\circ}$ and $80^{\circ}$	37.30
Fraction L1	19.50
Fraction L2	19.17

The amount of potassium xanthate may also be estimated by means of a standard iodine solution. The author, however, found that with pure carbon disulphide the results were about 2.5 per cent. too low. In order to remove the carbon disulphide the following method was adopted:—From 1,000 to 1,200 grms. of first runnings are placed in a flask and treated with from 5 to 6 times the weight of alcohol, the flask and contents being kept in a cooling mixture to prevent loss by evaporation. A constant stream of dry ammonia is then introduced through a wide glass tube until the separation of solid xanthate is complete, when the mixture is filtered rapidly through a cotton filter, the filtrate being collected in a separating funnel. The lower layer contains the alcohol, some water and a small amount of hydrocarbons in solution. In order to separate the latter the mixture is diluted with water, the product thus obtained is then added to the upper layer and the whole subjected to another treatment with alcohol and ammonia. It is advisable to repeat this operation a third time in order to ensure the complete removal of all sulphur compounds. The hydrocarbon liquid is then washed thoroughly with water and dehydrated with calcium chloride. The removal of carbon disulphide reduces the specific gravity considerably; thus in the case of fraction L1 it fell from 0.8148 to 0.7401.

2. *Nitriles and Isonitriles*.—Vincent and Delachanal found acetonitrile in light benzene to the extent of from 50 to 70 per cent. Nocting detected the presence of an isonitrile, and showed that in spite of the small proportion of poisonous ingredients found in the first distillate from benzene, the working of light benzenes on a large scale may under certain conditions produce poisonous effects. He quoted a fatal case which occurred at a factory in Thann, where a workman having inhaled the vapour of

isonitrile died from its effects. For the quantitative estimation of nitriles the author used the following method:—A measured quantity of light benzene was boiled in a flask provided with a reflux condenser for 12 to 15 hours, with half its weight of concentrated hydrochloric acid. The brown mass thus obtained was evaporated to dryness, extracted with hot water, the solution filtered off, again treated with hydrochloric acid, evaporated and extracted with water. This operation was repeated until the residue was coloured only slightly yellow. It was then dissolved, treated with hydrochloric acid, evaporated to dryness in a tared dish, dried at  $100^{\circ}$  and weighed. The following results were obtained:—

	Per Cent. Nitrile.
Light benzene boiling between $36^{\circ}$ to $80^{\circ}$	7.49
Fraction L1	11.93
Fraction L2	10.03

3. *Aldehydes and Ketones*.—From the circumstance that aqueous solutions extracted from light benzene reduce ammoniacal silver solutions, the author concludes that aldehydes are contained in the first runnings from benzene. He treated a large quantity of fraction L1 with sodium bisulphite, but obtained only about 1 per cent. of extract, and was, therefore, unable to examine the mixture of aldehydes and ketones more closely. He, however, detected the presence of acetone by the characteristic odour, the formation of iodoform and the indigo reaction with orthonitrobenzaldehyde and sodium hydroxide. According to Michael a bright yellow resinous substance is obtained on boiling aldehyde with an alcoholic solution of resorcinol and a minute quantity of hydrochloric acid (see this Journal, 1884, 253). The author has obtained a similar product by applying the same reaction to light benzene.

4. *Ethyl Alcohol*.—The author has not been able to isolate this product from any of the fractions obtained by the distillation of light benzene. He, however, obtained a faint reaction for ethyl alcohol from a sample which had been in contact with water for a fortnight, and concludes from this result that light benzene contains an ethyl compound which is gradually decomposed by water with formation of ethyl alcohol.

5. *Phenols*.—The examination for phenols was conducted in the following manner. After treatment with hydrochloric acid the light benzene was shaken up with dilute soda lye. The alkaline extract was then acidified with sulphuric acid and distilled with steam or extracted with ether. In both cases a product having a tarry odour was obtained, but the quantity was too small to admit of further investigation.

6. *Mercaptans*.—To detect the presence of these compounds in light benzene the different fractions were heated with mercuric oxide and alcohol, and in a second series of trials they were added to an alcoholic solution of mercuric chloride. The presence of mercaptans could not, however, be established with certainty, as only a slight turbidity was obtained.

7. *Detection of Bodies belonging to the Pyrrol-, Thiophen-, and Furfuran Series, also of Hydrocarbons of the Benzene Series*.—The vapour from fraction L1 imparts a greenish colour to pine shavings moistened with hydrochloric acid. The reaction with phenanthraquinone and with isatin and concentrated sulphuric acid gave no colouration, so that it may be inferred with certainty that no closed chain compounds of the pyrrol, furfuran, or thiophen series are present. It was not possible to separate aromatic hydrocarbons by treatment with a concentrated solution of picric acid, although benzene was found in the residue obtained by fractional distillation.

8. *Unsaturated Compounds*.—The different fractions from the distillation of light benzene absorb bromine very eagerly, and form additive as well as substitution compounds. The group of unsaturated compounds includes derivatives of acetylene, the author having found that on adding an ammoniacal solution of cuprous chloride to light benzene and allowing the mixture to stand, a red-brown precipitate is obtained.—D. B.

*By-products of Wood Distillation.* Vldesco. Bull. Soc. Chim. 1890, 3, 510—514.

THE author has examined two samples obtained during the rectification of methyl alcohol in wood distillation. Both samples combined with sodium monosulphite, and did not reduce silver nitrate in ammoniacal solution, thus indicating the presence of higher ketones.

*Sample No. 1*, distilling 85°—140°, was washed with distilled water to remove any soluble portion. The insoluble part was treated with sodium monosulphite, with which it combined to form a solid substance, with the exception of a certain quantity of liquid, which separated uncombined. The combined portion was recovered by distillation with sodium carbonate, and fractionated, distilling chiefly at 99—102°.

The analysis, together with the fact of its combining with sodium monosulphite and not reducing ammoniacal silver nitrate, pointed to the probability of this substance consisting chiefly of one of the three isomeric ketones, with 5 atoms of carbon.

The author proved it to consist of methylpropyl ketone. The identity was established by analysis and examination of the product obtained by treatment with phosphorus pentachloride, by obtaining the corresponding alcohol, by the action of sodium amalgam, and also by obtaining the corresponding pinacone.

The uncombined portion consisted of a mixture of toluene and xylene. The portion soluble in water was methylethyl ketone, as in the following sample.

*Sample No. 2*, distilling between 70°—143°, of this, 75 per cent. dissolved in water. The insoluble proved to be identical with the foregoing insoluble part. The soluble portion was separated with potassium carbonate, and treated with sodium monosulphite, with which almost the entire quantity combined. After recovery, it was fractionated, distilling chiefly between 79°—82°, the boiling point of methylethyl ketone, with which it was identified by analysis.

As the price of these ketones in commerce is high, the author considers it would be advantageous to produce them from the above-mentioned products, in which they occur in notable quantity.—D. A. S.

#### The Recent Investigation of Naphthenes or Polymethylenes.

V. Markovnikov. J. Russ. Chem. Soc. 22, 275—279.

SINCE the investigation of hydrocarbons from Caucasian naphtha were commenced some years ago in the author's laboratory, the nature and the object of these researches have been considerably altered. Their chief object having formerly been the study of the composition of naphtha, they are now principally directed to the general and individual properties of the new class of hydrocarbons found in naphtha, and generally termed polymethylenes or naphthenes, in order to determine the relationship to other classes of organic compounds. The investigation of nononaphthene  $C_9H_{18}$  and its derivatives, by Kononov (J. Russ. Chem. Soc. 22, 118—148) is the first of the new researches, while several others of the same nature are being carried on in the author's laboratory.

However, the author finds it even now possible to make several generalisations concerning this class of compounds.

(1.) The identity of hexanaphthenes, hexahydrobenzenes, and hexamethylenes, long ago foreseen by theory, may be now considered almost proved by facts—

represents the only possible construction for all three. Although these simplest members of the series have not been studied yet in the pure state, the identity of some of their derivatives is proved beyond doubt.

Octonaphthene is hexahydrometaxylene; iso-octonaphthene is but the para derivative of the same aromatic

hydrocarbon. Nononaphthene, according to M. Kononov, is hexahydro-pseudocumene, &c. On the other hand, the identity of the hexahydrobenzenes and hexamethylenes may also be considered as established after the research on succinyl ether by Baeyer (Ber. 19, 428).

(2.) But beyond the  $C_6$  methylene group there may exist other methylene groups of  $C_3$ ,  $C_5$ ,  $C_4$ ,  $C_7$ , and, indeed, trimethylene and pentamethylene had already been obtained; hexamethylenes and tetramethylenes are known in the form of their derivatives. Some chemists had been inclined to doubt the possibility of the existence of heptamethylene but the author succeeded in obtaining it from suberone.

(3.) All these hydrocarbons having analogous structure ought to possess analogous properties, therefore they may be all classified as polymethylenes or naphthenes of the general formula  $C_nH_{2n}$ , and placed according to their chemical character between the aromatic series with the group  $C_6$ , and that of the paraffins, without adopting any special fixed group at all.

(4.) The well-known relation of the terpenes to the benzenes and the recently-established connexion between these hydrocarbons and the naphthenes, induce the author to regard them as a third isologous series of  $C_nH_{2n-4}$ ; the second series being formed of naphthylenes or unsaturated derivatives of naphthenes, of the general formula  $C_nH_{2n-2}$ . Thus, all derivatives of 4-atomic terpenes become derivatives of decanaphthenes; whilst those of 2-atomic terpenes ought to be classified with the decanaphthylenes.

(5.) It is remarkable that the boiling points of polymethylenes are almost the same as those of the paraffins with the same number of atoms of carbon in the molecule.

$C_5H_{12}$ 37°;	$C_6H_{14}$ 67°;	$C_7H_{16}$ 100°;
Normal pentane.	Hexane.	Heptane.
$C_5H_{10}$ 35°;	$C_6H_{12}$ 69°;	$C_7H_{14}$ 98°—100°;
Pentamethylene.	Hexamethylene.	Heptamethylene.
$C_5H_9.CH_3$ 70°—71°;	$C_6H_{11}.CH_3$ 99°;	
Methylpentamethylene.	Hexahydrotoluene.	
$C_6H_{10} 2 CH_3$ 123°—124°;	$C_6H_{10} \left\{ \begin{array}{c} C_2H_5 \\ CH_3 \end{array} \right\}$ 150°—152°;	
Iso-octonaphthene (para).	Methylethylhexamethylene (ortho).	
$C_5H_8 \left\{ \begin{array}{c} C_2H_5 \\ CH_3 \end{array} \right\}$ 124°;	$C_7H_{11} 2 CH_3$ 150°—152°.	
Methylethylpentamethylene (ortho).	Dimethylheptamethylene (ortho).	

These considerations and data make the author inclined to suspect that the naphthenes from Caucasian naphtha are mixtures of analogous members of different series of polymethylenes. For every additional  $CH_2$  in the carbon group the boiling point rises from 30° to 34°.—N. W. T.

#### PATENTS.

*Improvements in Distilling Shale, Coal, or other Oil and Tar-yielding Minerals, and in Retorts therefor.* A. Neilson, Inkerman, and W. Black, Airdrie. Eng. Pat. 9783, June 14, 1889. 8d.

THE retort is built of fire-brick in the form of a large cylinder and preferably encased by a shell of iron or other material to exclude air. A hopper is fixed on the top to which the sheet iron is securely jointed. A door is also fixed at the bottom for the removal of the residue from the retort. A jet of steam and a supply of air are introduced into the retort at or immediately above the lower door, both of which can be regulated according to the heat required. The retorts may be built singly or in groups, but no arrangement for furnaces or flues is required, the whole heating being obtained from the combustion of the material within the retort itself. The retort when applied to shale distillation for oil is preferably built in a vertical position. It is of great height and large dimensions and may be oblong at the bottom, tapering slightly and regularly narrower toward the top. Its action is practically continuous, a portion being drawn from the bottom and another fresh portion

charged at the top at regular intervals. In distilling shale for oil the retort is heated up and a quantity of spent shale left in the lower part of the retort, the upper part being charged with fresh shale. A jet of steam with the necessary amount of air is then admitted at the bottom to carry on the combustion of the spent shale, the hot gases from which pass up through the mass of fresh shale, whereby the oil products are distilled. In order to regulate the heat and at the same time improve the quality of the products, steam, gas from scrubbers, spent ammonia, or lined water may be introduced, and in cases in which there is insufficient carbon in the spent material to maintain the necessary heat in the retort, a small quantity of coke breeze, cinder, or anthracite coal may be charged along with the material to be operated on.—D. B.

*Improvements in the Distillation of Mineral Oils and like Products, and Apparatus for that Purpose.* J. Dewar, Cambridge, and B. Redwood, London. Eng. Pat. 10,277, June 24, 1889. 8d.

This invention relates to a method of conducting the distillation of mineral oils in such a manner that the benefit of regular vaporisation under high pressure is obtained, and also at the same time such advantage as can be got from the operation commonly termed "cracking." For this purpose the inventors propose to arrange a suitable boiler and a condenser in free communication with one another, the latter being provided with a regulated outlet for condensed liquid. The space in the boiler and condenser which is not occupied by liquid is charged and kept charged with air or, preferably, with carbonic anhydride under considerable pressure, so that the distillation is also conducted under great pressure which can be regulated at will. In this manner the inventors claim to obtain from the residue of heavy oil a quantity of light oil suitable for illuminating purposes which cannot be obtained by distillation under the ordinary pressure. The upper part of the boiler may also be so arranged as to operate according to the cracking method, the cracking in this case taking place under high pressure.—D. B.

*Improvements in Coke Ovens.* C. Heucken, Aix la Chapelle, Germany. Eng. Pat. 3363, March 3, 1890. 8d.

THESE improvements are in the construction of bee-hive ovens modified for the recovery of the products of distillation, and permit of the ovens being heated from the floor and sides, and not from the floor only as is usual; in this way the time of coking is brought down to the amount required for ovens of the more modern systems, without any deterioration of the high quality of the coke produced. The cross section of the improved ovens is slightly elliptical, that shape permitting of a convenient door at one end of the minor axis without detriment to the floor flues of the oven. The space beneath the floor of the oven is divided by a partition into two parts not communicating with one another, and each divided into seven flues partially open to each other and communicating on each side with an equal number of side flues of varying width, all of which pass into an arched flue placed around the periphery of the oven dome. This arched flue is divided by partitions into three compartments, one of which contains convenient openings into the oven, and another is connected with side flues leading to the chimney. The gases in the oven pass through the openings in the dome into one division of the arched flue, then down one set of side flues through the flues under one half of the floor and up through one set of flues on the opposite side into the second division of the arched flue; they are then forced down the adjacent set of side flues, through the flues under the second half of the floor and up through the opposite set of side flues into the third division of the arched flue, from which they finally escape into flues leading to the chimney. There are convenient openings for observation, supply of air, &c.—S. B. A. A.

## IV.—COLOURING MATTERS AND DYES.

*α-Naphthol-Benzoin.—A New Indicator.* R. Zaloziecki. Chem. Zeit. 14, 605—606.

See under XXIII., page 770.

*The Action of Fuming Nitric Acid on Hexachlorobenzene.* Istrati. Bull. Soc. Chim. 1890, 3, 184—186.

Fuming nitric acid attacks hexachlorobenzene energetically, forming dichlorodihydroxyquinone; this, in fact, is the best method of preparing the latter body, as an excess of nitric acid does not destroy it. It appears in this reaction that (1) the chlorine in the benzene nucleus is partially removed and replaced by oxygen, this action being accompanied (2) by the evolution of a gaseous mixture of 62—64 per cent. of nitrous gases and carbon dioxide, 34—39 per cent. of oxygen, and 4—7 per cent. of nitrogen.—E. B.

*A New Method of Chlorinating Aromatic Compounds.* Pétricon. Bull. Soc. Chim. 1890, 3, 189—191.

THE author recommends stannic chloride for assisting the chlorination of benzene compounds. The stannic chloride is preferably used "in the nascent state," being produced by the action of chlorine on metallic tin in admixture with the compound to be treated. Compared with iodine, antimony pentachloride, &c., stannic chloride has the following advantages: the chlorination is effected in a shorter time; it is especially useful in the preparation of higher chlorinated derivatives such as, for instance, pentachlorobenzene; its action is well defined, a more limited number of compounds being produced than when iodine is used; very little decomposition takes place of the aromatic compound under treatment.—E. B.

*The Action of Sulphuric Acid on Tribromophenol.* Georgesco. Bull. Soc. Chim. 1890, 3, 193—195.

HERTZIG has stated that tribromophenol is destroyed by boiling for four hours with sulphuric acid. The author, guided by the results obtained by Istrati with the chlorobenzenes, has re-examined the reaction. On heating together a mixture of tribromophenol and sulphuric acid for 20 hours on a sand-bath, action takes place accompanied by the evolution of considerable quantities of gas, consisting chiefly of sulphur dioxide along with small quantities of carbon dioxide and hydrobromic acid, the sulphuric acid at the same time becoming deep red-brown in colour. A precipitate separates when the acid mixture is poured into water. This precipitate consists of brominated fractions containing from 42·137 to 63·786 per cent. of bromine, and having the characteristic brown colour, high melting point, and other properties of this class of bodies. In the flask used for the experiment there remained a solid substance, which was found to be a mixture of unaltered tribromophenol, tetrabromophenol, pentabromophenol, and a red substance, with difficulty soluble in hot benzene, crystallising therefrom in small plates, which sublime without melting or decomposition at 250°—258°. It was not obtained in sufficient quantity to permit of an analysis being made. Pentabromophenol is a crystalline rose-coloured body melting at 220°.

When, as in Hertzig's experiment, the action of the acid is continued for four hours only, the result is similar, the higher brominated derivatives, however, being formed in smaller amount.—E. B.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

*Thermo-Chemical Investigations on Silk.* L. Vignon.

Bull. Soc. Chim. 1890, 3, 405—410.

See under XXIII., page 771.

*Distinction between Jute, Flax, and Hemp Fibre.* W. Lenz.  
Zeits. Anal. Chem. 29, 133—134.

JUTE is of course recognised by its peculiar structure, chiefly by the irregularly thickened walls of the bast fibres. To be able to make use of such distinction requires a great deal of care and considerable practice. An easier method seems to be by the aid of polarised light. The fibre is warmed with nitric acid and a grain of potassium chlorate, washed with water, then warmed with water containing a little caustic potash, and finally well shaken with pure water. A portion is brought on to a microscope slide, and the moisture is allowed to evaporate; a drop of glycerin is now added and a cover glass laid on. Not only are the peculiar thickenings now well shown under the microscope, but the specimen serves especially well for examination by polarised light. With a crossed Nicol, using a magnifying power of about 200, a beautiful play of colours is obtained with almost every fibre in the case of flax and hemp, whilst with jute only yellow or bluish single shades are obtained; occasional fibres show the colouration of the flax, but not to such a marked degree. It is necessary to have the individual fibres well separated, for colourations are obtained with jute if the individual fibres cross or run counter to each other. The cross lines running at right angles to the walls of the bast cells are much more distinct in polarised light with a magnifying power of 600 than they are in ordinary light.—T. L. B.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*Methods of Dyeing pursued by the Chinese.* Chem. Ind.  
13, 154—157.

FOR dyeing yellow, the bark of a large tree, the *Pterocarpus flauus* (Chinese name, huang pei), is employed. Silk is softened in boiling water, and immersed in a solution of the colouring matter of the bark, prepared in the cold, and is then dried in the shade. The colour is not fast to hot water. Cotton is first worked in a liquor prepared by steeping meizu plums in water for several days, then the solution of the yellow colouring matter is added to the liquor, and the cotton cloth is passed through the bath until fully dyed, which requires sometimes as many as 80 immersions, and the cloth is finally dried in the shade.

Gamboge (Chin., teng huang) is employed chiefly for painting.

The bark of *Berberis thunbergii* (Chin., hsiaopei), and the wood of *Dereilla versicolor* (Chin., hang lou) are also employed.

Turmeric (Chin., kiang huang) is largely used.

*Rhamnesia linensis* (Chin., tihuang), and the buds of *Sophora japonica* (Chin., huai hua or hua ni), are also used for dyeing yellow, the former extensively.

Five different qualities of indigo are in use for dyeing blue. The indigo vat is prepared by gently heating for some time a mixture of indigo, oat- and rice-refuse, and lime.

Silk is dyed green by mordanting it first with alum, dyeing yellow with hwaimi, and then dipping in an indigo vat set with Shanghai indigo. In dyeing cotton, the order of the operations is reversed, a blue colour being first dyed, and then, after mordanting with alum, a yellow.

The preparation of Chinese green is described in the original paper. The price of this colour has fallen from 225 frs. in 1865 to 66 frs. per kilo. at the present time.

For dyeing red there are employed the following dye-stuffs: Safflower (*Carthamus tinctorius*), the roots of lithospermum erythoxylon, sanderswood, sapanwood, and madder.

Vermilion and sapanwood are employed for dyeing brown on cotton or silk, which has been previously dyed blue with indigo. Bright reds are obtained by treating white silk or cotton with these materials.

Grey is produced by working blue-dyed cotton or silk in a decoction of the nut-galls of *Rhus semialatus*.

In dyeing black, the leaves and husks of *Mimosa ferox* and gull-nuts are employed along with ferrous sulphate. Another black is obtained on dark blue-dyed fabrics with hwa kuo and black alum.

There are some 10 fairly large dye-houses in Shanghai, employing about 400 hands.—E. B.

*Dye-Wood Extracts, and their Modern Manufacture.*  
J. H. Soxhlet. Chem. Zeit. 14, 667.

THIS industry sprang up in France at the beginning of this century, Meissonier being the first manufacturer of a liquid and solid material suitable chiefly for printing. Logwood is occasionally submitted to a process known as "oxidation" before being placed in the extractors. The chips are spread out in thin layers, and moistened with water containing in solution or suspension the following substances: ammonium chloride, ammonium carbonate, putrid urine, chalk, clay, saltpetre, potassium permanganate, and bichromate; the exact procedure being kept secret. This "oxidation" must be condemned, owing to the fact that the resulting extracts yield much less permanent colours.

The extraction of the colouring matter from the wood is conducted either by maceration in open vessels—French method—or under steam pressure at high temperatures, as first employed by Lanford in America. The yield of extract at 45° B. by the former process is 16½ per cent., by the latter from 20 to 21 per cent. For printing purposes, the "French" extract is to be preferred, higher prices being obtainable, but for dyeing woollen yarn, where fastness rather than purity of tone is necessary, the "American" extract is better. The "French" extract is often adulterated with molasses, glucose, dextrin, &c., to the extent of 50 per cent. in the cheaper qualities.

In America logwood extract is sold under the name of "black dye extract," adulterated with quercitron and hemlock; and fustic extract, called "substitute for fustic," adulterated with quercitron.

Extracts manufactured under pressure usually contain more woody particles than the "French." To avoid this, the liquors may be allowed to subside before evaporation, or they may be filter-pressed, or precipitated with salt or sodium sulphate.

The pressure in the pans should not exceed 1 or 1½ atmospheres.—F. H. L.

*A New Bleaching Process.* Kassner. Monit. Scient.  
1890, 103.

THE author proposes to take advantage of the well-known oxidising action of potassium ferrieyanide in presence of alkali. The resulting ferrocyanide is oxidised by digestion with peroxide of lead, the action being facilitated by passing a stream of carbonic acid. The deposit from this operation is dried, and the lead peroxidised by calcination, the product being boiled with sodium carbonate solution, and the precipitated peroxide used as above.—C. F. C.

*The Chroming of Wool.* Scurati-Mauzoni. Mon. de la teinture, 1890, 34, 29.

IN order to determine whether on treating wool with bichromate, the fixation of the chromium is due to the reducing power of the wool itself, or to organic sulphur compounds contained by it, the author has examined the final liquor and found that it contained potassium sulphate, which increased in quantity with the length of the boiling; that the colour of the wool was proportional to the amount of sulphate formed, and that by long-continued boiling the

wool became green, whilst the liquor remained yellow as long as it contained bichromate.

If the treatment with bichromate be allowed to take place under pressure (two atmospheres for three hours), then at the conclusion the liquor contains no more bichromate, the wool becomes a dirty green, shrinks together and is quite valueless, and the interior of the vessel is blackened.

It is thus evident that it is the sulphur contained in the wool which produces the reduction, being itself oxidised to sulphate. The author has shown that finely divided sulphur is capable of thus acting by impregnating wool with sodium thiosulphate, treating with hydrochloric acid, which causes a deposit of sulphur in the wool, and after washing, treating with bichromate; after half an hour's boiling this is reduced and the hydroxide deposited in the wool, the finely divided sulphur first forming sulphuretted hydrogen which performs the reduction. The same effect may be produced by a stream of sulphuretted hydrogen. The practical objection to both these methods is that two operations have to be performed. The author has attempted to find a sulphur compound which might be added with the bichromate to the bath. He has found the potassium tri- and tetra-thionates and sodium tri-thionate the most efficient. They may be kept mixed with the bichromate in the cold without action, and by warming produce a slow reduction. For 100 grms. of wool, 2.5 grms. of potassium bichromate and 8 grms. of potassium tri-thionate are dissolved in 5 litres water, and boiled one hour. It is evident that the price of the thionate must be considerably reduced before its use becomes practicable. (See this Journal, 1890, 58—61.)—A. L. S.

#### PATENT.

*Manufacture of Bleaching and Disinfecting Liquor.* E. Hermite, E. J. Paterson, and C. F. Cooper, London. Eng. Pat. 8177, May 16, 1889. 4d.

Blocks of carnallite are by mechanical means divided up into three portions, one of which is a double chloride of

magnesium and potassium. This is dissolved in water and a current of electricity passed through the solution (see this Journal, 1887, 727; and 1888, 126 and 321), which is thereby decomposed and may now be employed as a valuable bleaching and disinfecting agent. Some magnesia is also liberated which is found to be advantageous as it renders the solution alkaline.—S. G. R.

### VII.—ACIDS, ALKALIS, AND SALTS.

*Reduction of Nitrous Vitriol by Coke.* G. Lunge. Zeits. f. angew. Chem. 1890, 195—196.

THE author has already shown (Chem. Ind. 1885, 2; also this Journal, 1885, 31) that the nitric acid gradually disappears from a mixture of nitric and sulphuric acids by contact with coke, even at ordinary temperatures; whilst at higher temperatures such disappearance is very rapid. Nitrosylsulphuric acid is formed. This observation led to an explanation of the fact that even in the Gay-Lussac tower containing nitrogen peroxide, the nitrous vitriol gave no marked evidence of the presence of nitric acid. Later on (Zeits. f. angew. Chem. 1889, 387) it was shown that the reducing action of the coke could extend even to the nitro-compound. The present work deals more in detail with this latter action of the coke.

Solutions of chamber crystals in pure sulphuric acid were used—the sulphuric acid being of two strengths, 1.8375 and 1.7250. The coke used was:—(a) gas coke, in pieces the size of a pea; (b) the same, roughly powdered; (c) hard oven coke in pieces; (d) the same, powdered. The experiments were made at the following temperatures, 15°, 40°, 70°, and 100° C., and were carried out in flasks closed by means of a Bunsen valve, the air being displaced by dry carbon dioxide. Amount of nitrogen trioxide was ascertained by running the acid into warm permanganate solution. The accompanying table gives the experimental results.

Material.	Temperature.	Duration in Hours.	Original $N_2O_3$ in Grms. per Litre.	Decrease.		
				In Grms. of $N_2O_3$ per Litre.	In Percentage of $N_2O_3$ .

II.—LIQUID OF SP. GR. 1.725.						
Gas coke, powdered.....	{	15	24	19.50	0.386	1.98
		40	2	19.50	0.574	2.94
		70	2	19.50	0.891	4.57
		100	2	19.50	3.410	17.49

Of course nitric oxide is evolved, and this must naturally escape unused from the Gay-Lussac tower. Some of the coke is also transformed into carbon dioxide, as was shown by displacing the air of the flask in one experiment by nitrogen instead of by carbon dioxide.

It is concluded that coke has here a reducing action, and the action increased with the temperature, and also with increase in the coke surface; the soft gas coke has a greater reducing action than the harder coke. A temperature of 40° may prevail in the Gay-Lussac tower in summer, and so after two hours' contact the nitrogen trioxide may be reduced to the extent of 2·4 to 4·5 per cent. The greatest reduction given (28 per cent.) takes place over 70°; this temperature never exists in the Gay-Lussac tower, but it may be found in the upper part of the Glover tower. The action is more pronounced in the case of solutions of nitrosyl-sulphuric acid in concentrated sulphuric acid than in the case of solutions in only moderately strong sulphuric acid.

The following practical conclusions are drawn:—It is useless to employ coke wherever the temperature rises above 70° C.; the upper portions of the Glover tower should not, therefore, be filled with coke, otherwise the acid becomes denitrated by coke instead of by sulphur dioxide; filling the Gay-Lussac tower with coke must lead to some loss (by evolution of nitric oxide). Nevertheless, by using hard oven coke in large pieces, and by not having the acid too strong, the action is more moderate, and so the coke may last also a considerable time. (See also this Journal, 1889, 164-168; 1890, 175-182.)—T. L. B.

#### *A Central African Salt Lake.* Chemist and Druggist. 37, 18-19.

"On the north of the Albert Edward Nyanza, and within a few miles of the equator, Mr. Stanley discovered the salt lakes of Katwe, 3,265 ft. above the sea. The temperature of the lake was 78·4° F.; a narrow thread of sulphurous water indicated 84°. Its flavour was that of very strong brine. A bottle full of this brine was brought to Cairo and analysed in the Laboratoire Khedivial there, and estimated by the chemists, Messrs. A. Pappe and H. Drop Richmond, to be composed as follows:—

Sodium chloride .....	18·67
Sodium sulphate .....	5·63
Sodium carbonate .....	2·72
Potassium carbonate.....	3·87
Water .....	68·77

"The residue is potassium sulphhydrate ·04, silica ·01, with traces of lime, magnesia, and organic matter. A sample of the natural crystalline salt taken from beds where the water had evaporated was brought, and is reported upon by Mr. Henry S. Wellcome, who, after giving the exact analysis of bases and acids, assumes the composition to be as follows:—

Potassium sulphate .....	8·43
Sodium sulphate .....	5·32
Sodium carbonate .....	2·46
Sodium chloride.....	82·71
Oxide of iron.....	0·15
Water.....	0·82"

#### PATENTS.

*Application of the Residues of Soda Manufacture for Building Purposes.* W. Schleuning, Heidelberg, Germany. Eng. Pat. 6433, April 15, 1889. 6d.

THE residues are exposed to oxidation so as to convert them into "soda gypsum"; burnt gypsum is added thereto, together with lime and sufficient water to form a mortar or plaster, or with little water to form a paste, which is subjected to pressure in suitable moulds, for the production of building blocks.—E. G. C.

*A Process first for Producing a Clean Gaseous Fuel to be used in the Evaporation of Brine, and secondly for Recovering the Ammonia formed during the Production of said Gaseous Fuel.* S. W. Wilkinson, Manchester. Eng. Pat. 8993, May 30, 1889. 6d.

COAL is burned in a closed furnace or producer with a limited supply of air and steam, so regulated that the gaseous products may contain a maximum of ammonia. The gases are passed through a scrubber or tank containing sulphuric acid which retains the ammonia; they are then led into a chamber consisting of chequer brickwork and there mixed with the quantity of air necessary for complete combustion. The ignited gas may be led over the surface of brine without any carbon being deposited. An arrangement is also shown for utilising the waste gases for heating brine tanks by means of flues, &c.—S. B. A. A.

*Improvements in the Manufacture of Phosphorus.* T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 10,437, June 27, 1889. 4d.

A SUITABLE material, such as a natural phosphate, is mixed with carbon or carbonaceous material in a furnace or crucible, together with a non-volatile metal, such as iron or copper. The whole is then kept at a sufficient temperature to effect the reduction by an electric current, the molten metal acting as a bath to keep the temperature more uniform. Phosphorus comes off as a vapour and is condensed by known means.—E. T.

*Improvements in the Manufacture of Carbon Bisulphide.* T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 11,099, July 10, 1889. 4d.

A MASS of charcoal is placed between two suitable electrodes, preferably constructed of carbon, which are connected with an electric current of sufficient density to bring the charcoal to the temperature necessary for it to combine with the sulphur, which latter is passed through the heated mass in the form of vapour. The supply of charcoal is renewed continuously or from time to time, either by hand or by automatic feeding arrangements. The vapours of carbon bisulphide are led off and condensed in the usual manner.—C. A. K.

*Process and Apparatus for the Production of Fuming Sulphuric Acid or of Sulphuric Anhydride from the Acid Waste or Residual Matter obtained in the Petroleum, Paraffin, and Tar Industry.* J. D. Starek, Iseheim, Bohemia. Eng. Pat. 12,028, July 29, 1889. 8d.

THE acid waste or other material is fed in at a proper speed to the lower end of an inclined iron retort within which is an endless screw working for the purpose of drawing outwards the residual coke-like mass. The sulphurous anhydride and water produced are passed through a condenser and a wash-chamber to remove any water or hydrocarbons coming over. The gas is then led through a tower similar to a Glover tower, to dry it completely, and mixed with dried air or oxygen in the required amount to form sulphuric anhydride. The mixture thus made is conducted through a tube filled with platinised asbestos, pumice stone, or metallic oxides precipitated upon porous bodies, and the sulphuric anhydride produced is either condensed or absorbed in sulphuric acid. The residual gases containing sulphurous anhydride are passed into lead chambers to be converted in the ordinary way into sulphuric acid. The specification is illustrated by drawings.—S. G. R.

*Improvements in the Treatment and Distillation of Ammoniacal Liquor of Gas and other Works, and in the Manufacture of Sulphate of Ammonia therefrom, and in the Apparatus to be employed therein, and for the Prevention of Nuisance in such Manufacture.* A. W. Ellis, London. Eng. Pat. 13,003, August 17, 1889. 1s. 3d.

THE specification is of great length and is illustrated by six sheets of drawings. Of these the most important is

THE DISTILLATION OF AMMONIACAL LIQUOR.

the one showing the general arrangement of the whole plant, and which is given above.

The liquors to be treated pass downwards from the overhead tank E, through the pipe *r* controlled by the tap *r'*, to the bottom of the heater G. In their passage upwards they are warmed by waste gases obtained in a manner which will be seen later. Here also any light tarry matters or scum are run off by the pipe *q* and the heavier portion or tar sinks to the bottom and is removed at *q'*. The now hot liquors pass away at the top by *i* into the distilling column F, and any gases evolved also escape to F by the pipe *h*. The distilling column F is made of iron and is preferably cylindrical in shape, and placed within it are a series of trays one below the other over which the liquid runs in a thin continuous stream. The plates are of special form. The liquid is then steamed and the free ammonia in the liquors is evolved and passes upwards to the top of E. The liquor in its passage downwards finally reaches the fixed ammonia still F<sup>1</sup>, which by means of a continuous horizontal partition is divided into two portions, an upper and a lower. The upper is again subdivided into three, one chamber being central and cylindrical, the other two annular, whilst the lower is made up of five divisions, one as before being central and the remaining four peripheral and annular. A steam coil passes through all the sections and any residual tar is here removed. Lime is introduced by the pipe *k*, and thus the fixed ammonia is liberated. The steam enters first into the chamber *d* in which is the oldest and most nearly exhausted liquor. This column is also cylindrical and made of iron. The spent liquors pass away at *n* to the settler D. The ammonia which has reached the top of the still F is led away by the pipe *h* to the saturator J, containing dilute sulphuric acid. The hot gases unabsorbed in J are passed through the interceptor K, also containing sulphuric acid, to remove the last traces of ammonia, and the hot gases, rich in sulphur compounds, are taken by the pipe *p* to the heater G, down

which they are carried by a coil to the condenser G<sup>1</sup> through which water is kept circulating. The residual gases, rich in sulphuretted hydrogen, pass off by the pipe *b* and can be treated by any of the known methods for the utilisation of that gas. The impure strongly smelling liquid separated in the condenser G<sup>1</sup> flows by *b'* to H, which is heated either by steam or by the nearly boiling spent liquors from the settling tank D and which are conveyed by the pipe *a*. The vapours given off are either led back to *p* and G by *p'* or may be treated for the recovery of cyanogen. The liquid in the saturator J, which should contain a slight excess of ammonia, is run into the steam-tight receiver I, where, either by the hot spent liquors from D which have already passed H or else by steam, every trace of ammonia, sulphuretted hydrogen, &c., can be driven off. The gases pass by *y'* to the interceptor K; *y* is a safety tube. In I any precipitate of sulphides of iron and arsenic separates out, and the clear liquor, which has been further concentrated by the steaming or heating to which it has been subjected, is run out and caused to crystallise. This residue in I is removed from time to time by a separate exit. For further details of the construction of the different parts of the plant, the original specification should be consulted.—S. G. R.

*Improvements in the Evaporation of Brine and other Solutions or Liquids, and in Apparatus employed therein.* J. C. Mewburn, London. From C. C. Peck, Warsaw, U.S.A. Eng. Pat. 6107, April 22, 1890. 1s. 1d.

See under I., page 728.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

*Red Glass.* C. Guignot and L. Magne. *Monit. Céram. et Ver.* **21**, 26.

THE authors consider the colour of red glass (coloured with copper) to be due to the presence of cuprous oxide, in opposition to the views of *Ebell*, who ascribes it to finely divided metallic copper (this *Journal*, 1888, 123; and 1890, 68). They found their contention on the fact that basic cupric chloride heated between two glass plates gives a red colour, holding that the soda in the glass reacts with the basic cupric chloride giving cuprous oxide and sodium chloride. Even admitting that cuprous oxide may at a high temperature decompose (*Proc. Chem. Soc.* **78**, 19) and the metallic copper dissolve in the glass with the formation of a red colour, yet this experiment must deal with a distinct phenomenon, inasmuch as it is completed at the softening point of the glass, provided air be excluded.

By fusing together 100 parts of sodium carbonate, 50 of calcium carbonate, 260 of sand, and 10 of cupric oxide, a green-blue glass is obtained; the same mixture with 15 parts of forge scale substituted for the cupric oxide gives a yellow glass; if now these be fused together they react upon each other and yield a dark green glass streaked with purple-red veins.—B. B.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Influence of Sea-Water on Portland Cement.* E. Candlot. *Monit. Céram. et Ver.* **21**, 42. (Compare this *Journal*, 1889, 543.)

THE nature and quantity of the water used are of influence on the setting of cement. Sea-water, by forming calcium chloride and sulphate by double decomposition of the magnesium salts it contains with the lime compounds present in the cement, retards the setting. Neat cement gauged with sea-water, is at first stronger than when fresh-water is used, but retrogrades after some months. Cement, when made up into mortar by admixture with sand, shows no such tendency; the use of sea-water may delay its reaching its full strength, but this is attained after the lapse of a year; this fact applies particularly to finely ground samples.—B. B.

*Magnesia Cements.* Sprechsaal, **23**, 247.

THE various cements for stone and terra-cotta depending on the formation of magnesium oxychloride, generally consist of Portland cement or hydraulic lime mixed with magnesia and any inert substance such as sand or granite, according to the use to which they are to be put, moistened with magnesium chloride, and applied to the surfaces to be repaired after moistening them with the same solution.

—B. B.

### PATENTS.

*Application of the Residues of Soda Manufacture for Building Purposes.* W. Schlenning, Heidelberg, Germany. Eng. Pat. 6433, April 15, 1889, 6d.

See under VII., page 734.

*Process and Apparatus for Producing Artificial Stone.* B. Mertelmeier, Berlin, Germany. Eng. Pat. 13,957, September 1, 1889. 8d.

THE powdered constituents are exhausted of the inherent air in a hermetically closed receptacle, and are afterwards mixed, by means of a stirring device within the receptacle, with "air-exhausted water." The product is then cast into moulds, and is said to be "equal or even superior in solidity and durability to natural stone." Drawings of the apparatus are given.—E. G. C.

*An Improved Manufacture of an Artificial Solid Material and Apparatus therefor.* H. H. Lake, London. From J. F. Gesner, New York, U.S.A. Eng. Pat. 1097, January 21, 1890. 11d.

MATERIALS made by mixing inert solids with alkaline silicates are not suitable for use as artificial stone, inasmuch as the alkaline silicate remains soluble and is liable to be washed out by rain. Attempts have been made to get over this difficulty by treating the stone with solutions of metallic salts such as calcium chloride, with the object of depositing insoluble silicates within the pores of the substance, but owing to its imperviousness thorough impregnation has been impracticable, even when the use of a pump or heated solution has been resorted to, or the mass mixed with sand to give it greater porosity. The patentee proposes a process, of which the following is an outline, to obviate these defects: Soluble glass either alone or, more generally, mixed with some inert solid, is allowed to dry in the air until it is stiff enough to be handled, and then subjected to what is termed "calcining." By this is meant the process of gradually raising its temperature above 212 F. until the combined water is driven off, and it swells to a light porous mass. If this be effected while it is confined in a mould which may be held together by springs, or a screw press with springs inserted to give a yielding pressure, it can be made to assume and retain any desired shape, and become reasonably compact although porous. On immersion in a solution containing some substance such as a free acid or a soluble base or a metallic salt capable of decomposing the alkaline silicate, rapid absorption takes place, after which the moulded blocks are usually washed, preferably by a spray of water, to remove soluble salts, dried, and if necessary pressed again, and if desired rendered impervious by treatment with some waterproofing substance such as paraffin wax, sulphur, fatty or resinous substances. The product may be coloured by the addition of some inert pigment to the soluble glass at the beginning of the process. Besides the finished article thus described, the material at the end of some of the steps of the process may be used for certain purposes. Various forms of press may be employed, and the heating effected in different ways; in that most approved and minutely described the mass to be treated is held between perforated metal plates covered with asbestos cloth, which fit into frames provided with a set of horizontal pipes for the transmission of steam (which may be superheated), a series of such arrangements being placed one above the other, and subjected to the action of a screw press provided with spiral springs to regulate the pressure.

The claims, which are 44 in number, deal with variations in the mixtures used, the conditions of manufacture, and the structure of the press.—B. B.

*Experiments on the Solubility of Minerals.* C. Dölter.  
Monatsh. **11**, 149—150.

See under XXIII., page 767.

*On the Reduction of Oxygen Compounds by Magnesium.*  
C. Winkler. Ber. **23**, 44—57, 120—130, and 772—792.

THE author has examined the behaviour of magnesium, the heat of combustion of which is very high, towards compounds containing oxygen. He gives the following results of experiments on the oxides and carbonates of the elements contained in the first group of the periodic system.

The substances under examination were previously dried or fused carefully in order to dehydrate, and then mixed in a warm mortar with the requisite quantity of powdered magnesium, and transferred to a glass tube sealed at one end. Owing to the difficulty of obtaining the oxides of the alkali metals pure, *i.e.* free from carbonate, water, &c., and retaining them in that state, it was decided to employ the carbonates.

A.—Chief Group (Carbonate  $R_2CO_3$ ).

1. *Lithium* (7.01).—On heating, violent detonation accompanied by the rapid combustion and vaporisation of the reduced metal. (Mixture being 1 mol. of the carbonate to 3 atoms of magnesium.)

2. *Sodium* (23).—(Mixture as before.) Detonation and vaporisation of the metallic sodium which partially condensed in the cooler part of the tube.

3. *Potassium* (39.03).—The reaction was quiet and safe; no deflagration or volatilisation of the metal. The reduction appeared to require less heat than was necessary in the case of sodium carbonate. By introducing the mixture into a porcelain boat and carrying out the reaction in a current of hydrogen in a combustion tube it was found that at a low red heat a metallic mirror was formed, further increase of temperature driving off greenish vapours. A greyish black residue consisting of magnesia and carbon remained in the boat, and as the residue was only slightly alkaline the potassium must practically have been driven over completely.

It seems, therefore, very probable that potassium can be prepared on a commercial scale in a similar manner, *viz.*, by heating freshly calcined potassium carbonate with magnesium in an iron retort, and condensing the potassium vapour in a suitable receiver. Illuminating gas could, however, hardly be substituted for the hydrogen as it contains carbon monoxide, which might form the dangerous explosive compound with the potassium, though in carrying out the process the presence of carbon monoxide can scarcely be avoided.

Of the three oxygen atoms in the molecule of potassium carbonate, two can be more easily taken up by magnesium than the third. This observation is of theoretical importance as it yields a proof of the constitutional formula—

also that the group OK is more easily reducible than the CO group. When 1 mol. proportion of potassium carbonate is heated with two atomic proportions of magnesium instead of three, the reduction must take place according to one or other of the following equations:—

(I.)

(II.)

It was found in the following experiment that the *second* equation represents the reaction.

A mixture of 138 parts (1 mol.) of potassium carbonate and 48 parts (2 atoms) of powdered magnesium was introduced into a combustion tube, at first heated gently and then to low redness, a moderately rapid stream of hydrogen being meanwhile passed through the tube. The metallic mirror observed in all the preceding experiments could not be seen, but instead in the cooler part of the tube was obtained a considerable layer of a green powder, which could be no other than the compound of potassium carbon monoxide; also no separation of carbon took place in the residue. The residue consisted of magnesia, so it may be taken that the formula of the potassium carbon monoxide compound is—

By heating together 56 parts (1 mol.) of potassium hydroxide and 24 parts (1 atom) of powdered magnesium, the reaction is very violent, but if 56 parts of magnesia be added, the reduction, which commences at a red heat, is quiet and safe, the residue remaining behind consisting of almost pure magnesia. This reaction may serve for the manufacture of potassium, employing the apparatus devised by C. Netto (this Journal, 1889, 122) for preparing metallic sodium continuously by allowing molten caustic soda to trickle through red-hot carbon contained in a vertical retort, the sodium which collects at the bottom being siphoned off. Instead of the carbon, bars of magnesium might be employed, though the magnesia formed at first may hinder further action by forming a coating on the magnesium.

The author gives the following data for the (theoretical) preparation of potassium:—

	M.
1.44 kilos. of potassium hydrate, at 2 M.....	2.88
0.62 kilos. of magnesium, at 10 M.....	24.80
	<hr/> 27.68

39 M. against 130 M., the present commercial price.

N. Beketow (J. d. russ. Phys. Chem. Gesellsch. Protok. 1888, 363—365) prepared potassium by reducing potassium hydrate with aluminium, but only half of the metal was obtained as such, the other half remaining in the residue as potassium aluminate.

4. *Rubidium* (85.2).—On gentle heating no reduction occurs, but on strongly heating the reaction takes place quietly, with a slight glow and partial volatilisation of the metal.

5. *Cesium* (132.7).—No reduction.

B.—Sub-group (Oxide  $R_2O$ ).

1. *Copper* (63.18).—Moderately strong decrepitation and partial deflagration.

2. *Silver* (107.66).—Reduction takes place with explosive violence.

3. *Gold* (196.20).—Quiet decomposition of the gold oxide into its elements, without the aid of the magnesium present.

The author's experiments, which disprove the statement of Warren (Chem. News, 1889, **60**, 187) that magnesium does not reduce the alkalis and alkaline earths, appear to show that the reducing power of the magnesium diminishes as the atomic weight of the element increases. This is in accord with the observation of Beketow, that, beginning at lithium and as far as rubidium, the heat of oxidation increases with the atomic weight.

The heavy metals belonging to the sub-group exhibit an opposite behaviour, *i.e.*, the reduction of their oxides is more violent the higher the atomic weight of the element. The anomalous behaviour of gold is only apparent, and is caused by the slight stability of the gold oxide at a high temperature.

## SECOND GROUP.

The reduction takes place according to the equation—

Some of the hydroxides as well as the oxides were experimented upon.

## A.—Chief Group (Oxide RO).

1. *Beryllium* (9.08).—Reduction takes place quietly, the mixture becoming dark coloured and glowing faintly, but the reaction is incomplete.

2. *Magnesium* (24.3).—No formation of a lower oxide.

3. *Calcium* (39.91).—Almost complete reduction, the mass becoming green coloured, but without glow.

4. *Strontium* (87.3).—Reaction commences quietly, the glow gradually extending throughout the mass. Reduction apparently complete.

5. *Barium* (136.9).—Tolerably violent reaction accompanied by strong glowing and partial ejection of the mass.

## B.—Sub-Group (Oxide RO).

1. *Zinc* (65.1).—Reduction takes place with explosive violence, accompanied by flame and decrepitation.

2. *Cadmium* (111.7).—Reaction commences with hissing noise and glowing of the mass. Complete reduction.

3. *Mercury* (199.8).—Powerful detonation accompanied by flame and complete volatilisation of the mercury.

From the foregoing it will be seen in the reduction of the oxides of the elements of the chief group, that an increase takes place, which, omitting magnesium, is in direct relation to the increase of atomic weight. The behaviour of the hydroxides is more marked. The reduction of the oxides of the sub-group is generally very violent, the reduced metal being volatilised completely or almost so.

## THIRD GROUP.

A.—Chief Group (Oxide R<sub>2</sub>O<sub>3</sub>).

1. *Boron* (10.9).—Boric anhydride and borax are easily reduced on heating with magnesium, the reduction of the latter being accompanied by delagration and volatilisation of sodium. Boron is never obtained, but magnesium boride of varying composition and behaviour towards acid. Hydrochloric acid either dissolves the magnesium boride completely with evolution of hydrogen mixed with boron, or leaves a solid residue consisting of a compound of boron and hydrogen. In keeping with the acid character of boron, acid borates are formed during reduction. A monoxide of boron does not appear to exist.

2. *Aluminium* (27.01).—Aluminium oxide on heating with magnesium forms a dark-coloured powder, the mixture glowing and swelling up during the reaction. According to the proportion of reducing agent employed, the aluminium is found in the above residue, either as finely divided metal or as monoxide. This monoxide, which up till now has not been known, could not be prepared in the pure state. The formation of the latter in accordance with the acid character is always accompanied by that of magnesium spinelle.

3. *Scandium* (43.97).—Omitted.

4. *Yttrium* (88.90).—Reaction takes place quietly, the mass glowing and blackening. Reduction apparently complete.

5. *Lanthanum* (138.6).—Reaction quiet, accompanied by tolerably strong glowing of the mixture. Apparently complete reduction.

6. *Ytterbium* (172.6).—Omitted.

B.—Sub-Group (Oxide R<sub>2</sub>O<sub>3</sub>).

1. *Gallium* (69.9).—Reduction accompanied by hissing noise and partial ejection of the mass.

2. *Indium* (113.6).—Violent detonation. A lower oxide could not be obtained by employing small quantities of magnesium.

3. *Thallium* (203.70).—Thallium oxide decomposes into the lower oxide and oxygen at a temperature below that necessary for reduction by magnesium. The suboxide formed is either not reduced at all or only incompletely

by magnesium, though the carbonate decomposes almost with explosive violence. The action of magnesium upon the oxides of the elements of the chief group increase only to a slight extent with the increase of the atomic weight. With boron there is an unmistakable tendency to combine with magnesium and hydrogen, and the acid character is also exhibited by the simultaneous formation of acid borates. Similarly, in the reduction of aluminium, a deficiency of magnesium results in the formation of a lower oxide before that of an aluminate.

The reducing action of magnesium on the oxides of the elements of the sub-group is very powerful, and increases with the atomic weight. The exceptional behaviour of thallium is only apparent, the previous decomposition of the thallium oxide sufficiently accounting for it.—O. H.

*Properties of Aluminium.* A. E. Hunt, J. W. Langley, and C. M. Hall. Eng. and Mining J. 49, 284—285, 314—316, 334—336.

*Purity of the Metal.*—The earlier information on the physical properties of aluminium is not very reliable, owing to the impurity of the metal, which rarely contained more than 95 per cent. of aluminium. More recently metal of 99 per cent. has been manufactured by Deville's process and by the electrolysis of alumina dissolved in a fluoride bath. In the first process the impurities are half silicon and half iron. In the latter they are mainly silicon. The latter impurity occurs chiefly in the graphitoid form.

*Specific Gravity.*—A table of the specific gravities of the metal, from various sources and variously treated, is given. The following values may be useful. Taking the specific gravity of aluminium as 1, that of soft steel is 2.95, of copper 3.6, of ordinary high brass 3.45, of nickel 3.5, of silver 4, of lead 4.8, of gold 7.7, a sheet of aluminium 12 in. square and 1 in. thick weighs 14.03 lb. A bar of aluminium 1 in. square and 12 in. long will weigh 1.17 lb. A bar of aluminium 1 in. in diameter and 12 in. long will weigh 0.918 lb. A cubic inch of cast aluminium weighs 0.092 lb. A cubic foot of cast aluminium weighs 158.967 lb. Aluminium has the tensile strength of cast iron, with only about one-third the weight. It may, therefore, replace the latter with advantage in the moving parts of machinery.

*Action of Heat.*—Pure aluminium melts at about 1,200° F. One per cent. of iron raises the melting point over 100°. Aluminium passes through a pasty stage, commencing at 1,000° F., and can be readily welded by pressure. It is very red-short at this temperature, and will not bear hammering. The metal is not injured by heating for a moderate period. The melting point of aluminium is given as 700° C. by Roscoe and Schorlemmer; by Deville it is stated to be higher than that of zinc, but lower than that of silver. Aluminium in a compact mass is chemically unaltered when heated under ordinary conditions by combustion of carbon at any furnace temperature, although it will burn readily in oxygen when in the attenuated form of thin foil. The presence of a flux is absolutely injurious, as it assists the absorption of silicon and iron from the walls of the crucible. When fused, the metal becomes coated with a thin film of oxide, which protects it from further action. It is best melted in plumbago crucibles, from which it absorbs .25 per cent. of silicon at each melting. Where it is desired to retain the purity of the metal, it may be melted in crucibles brasqued with pure magnesia mixed with sufficient tar to give it plasticity. Aluminium is most malleable between 200° and 300° F., but can be rolled or drawn cold with frequent annealing. It becomes red-short at 400° F. The annealing of aluminium is best carried out by heating it to a temperature of 800° F. At this temperature a bar of iron appears of a dull red in weak daylight. A piece of pine-wood drawn across the metal should leave a streak of carbon, which should burn away very slowly. Small articles may be annealed by plunging them in boiling linseed oil or water, and allowing them to cool with the liquid.

Aluminium when slowly cooled from fusion crystallises in octahedra. When pulled in a testing machine a granular fracture is obtained. If aluminium is cooled rapidly the

silicon does not combine with the metal and its hardness is not increased. The specific gravity of aluminium is 2.143 (Richards). The coefficient of linear expansion of metal of 98.52 per cent. (Pittsburg Reduction Company) is .0000206 per  $1^{\circ}$  C. between  $0^{\circ}$  and  $100^{\circ}$ , a value approaching that for tin and higher than that for copper. Sound castings of aluminium can be obtained in dry sand moulds preferably lined with plumbago. The metal should be heated to a temperature very little above its melting point and should be poured quickly. The shrinkage of the above metal is  $0.2\frac{1}{2}$  inch to the foot (2.26 per cent. of the length of the mould).

Aluminium, when exposed to the air, becomes coated with a very thin layer of oxide, which does not interfere with the surface polish but prevents the oxidation from going further. It is equally stable in the presence of steam and hot air. It is unacted upon by sulphuric acid and nitric acid if these acids be free from hydrochloric acid. It is not attacked by sea-water nor by weak solutions of salt in acetic acid.

Aluminium is a very soft metal, but is hardened by cold working. Castings can be hardened by being drop-forged in dies if not required to bear a great weight. As above mentioned aluminium is not hardened by chilling.

Aluminium is very ductile and malleable. In fact the latter property is a very good test of its purity. It is absolutely non-paramagnetic if it contain less than 0.05 per cent of iron. With .15 per cent. of iron a slight polarity was observed. With 2 per cent. the polarity was distinct.

The tensile, crushing and transverse tests of aluminium vary considerably according to the amount of work which has been put upon the metal. The flow of the metal under tensile tests is very local, the percentage of elongation decreasing very rapidly as it is calculated in increasing lengths from the point of fracture. Metal containing:—

	Per Cent.
Aluminium from.....	97—99
Silicon, graphitic, from.....	0.10—1.00
Silicon, combined.....	0.90—2.80
Iron.....	0.04—0.20

gave the following average tension and compression tests:—

Elastic limit per square inch in tension:	Pounds.
Castings.....	6,500
Sheet.....	12,000
Wire.....	16,000
Bars.....	14,000
Ultimate strength per square inch in tension:	
Castings.....	15,000
Sheet.....	24,000
Wire.....	30,000
Bars.....	28,000
Percentage of reduction of area in tension:	Per Cent.
Castings.....	15
Sheet.....	35
Wire.....	60
Bars.....	40
The modulus of elasticity of aluminium:	
In castings, is about.....	11,000,000
Sheets.....	13,000,000
Drawn wires.....	19,000,000
Elastic limit per square inch under compression in cylinders with length twice the diameter.....	3,500
Ultimate strength per square inch under compression in cylinders with length twice the diameter.....	13,000

Taking the tensile strength of aluminium in relation to its weight, it is as strong as steel of 80,000 lb. per square inch.

**Conductivity and Electro-chemical position of Aluminium.**  
—Aluminium is more electro-positive than any other metal, with the exception of the metals of the alkalis and alkaline earths. It is electro-positive to sodium in oxygen compounds since it liberates that metal from its oxide. When combined with sulphur it is electro-negative to iron. Its heat of combination with oxygen is about three times that of an equivalent quantity of carbon ( $C + O_2 = 96,000$  h.u.,  $Al_2 + O_3 = 388,000$  h.u.) The great affinity of aluminium for oxygen is made use of in the removal of oxygen from

molten steel by its means. At ordinary temperatures it resembles platinum and gold, and in nitric acid is nearly as electro-negative as platinum or carbon. It has been suggested that at low temperatures the atoms of aluminium are combined with one another. The following is the electrical resistance of aluminium (of 98.52 per cent.) as determined by C. K. McGee, of the University of Michigan:—

Specimen used.	Diameter in Inches.	Resistance in "Legal Ohms." of 1 Yard.	
		At $14^{\circ}$ C. (57 $^{\circ}$ F.).	At $76^{\circ}$ C. (176 $^{\circ}$ F.).
Unannealed Al wire.....	.0325	.05749	.07202
Annealed Al wire.....	.0325	.05484	.06928
Pure copper wire has the following resistance.....	.0325	.0315	.0387

The thermal conductivity of aluminium is nearly inversely as its electrical resistance, the thermal conductivity of aluminium being to that of copper as 1:1.88.

**Action of Impurities.**—Silicon hardens aluminium considerably, increasing its tensile strength without materially decreasing its ductility; it, however, very materially reduces its malleability, and takes away its capacity of taking a high polish and even prevents its retaining whatever polish it has received. Silicon in aluminium oxidises by the action of the atmosphere or of moisture, and if present in proportions above 3 per cent., very soon coats the metal with a dull grey and unsightly varnish. For certain purposes where it is desired to retain the lightness of the metal and where the polish is of no consequence, an alloy containing 6—8 per cent. of silicon is advantageous. As before remarked, the silicon is in the graphitoid state. Were it possible to convert it into the amorphous form a metal having the advantageous hardness without the tarnishing qualities might be obtained. Iron in small quantities hardens aluminium, but at the same time increases its specific gravity and renders it magnetic. It also reduces the malleability and injures the polish of the metal. If equal parts of aluminium and iron are melted together, an apparently true alloy is obtained which, however, on solidifying soon crumbles to powder. Aluminium may be advantageously alloyed with copper. The latter adds hardness and decreases the shrinkage of castings. Carbon combines with aluminium only at very high temperatures and in proportions not greater than 3 per cent. It renders the metal brittle and porous.

Sulphur combines with aluminium only at a very high temperature, and is not usually found in aluminium of commerce. Lead occurs in proportions up to  $\frac{1}{4}$  per cent. It has no appreciable influence on the properties of the metal. Antimony does not unite with aluminium. Chromium alloys readily with aluminium, increasing the hardness and tensile strength of the metal, but decreasing its malleability. Tungsten hardens aluminium, but gives no useful alloys. Platinum unites readily with aluminium, but the alloys are brittle and unsound. The most useful metal for improving aluminium seems to be silver. Five per cent. of silver increases the elasticity and hardness of aluminium without injuring the malleability of the metal. The alloy will also take a very fine polish. The addition of tin to aluminium renders the latter brittle, but it appears that 2 per cent. of aluminium added to tin renders the latter metal harder and more elastic. Cadmium unites with aluminium, giving fusible and malleable alloys; the aluminium is, however, weakened. Bismuth forms brittle, very fusible alloys. Nickel, in quantity, produces brittle alloys. In amounts less than 3 per cent. it increases the hardness without injuring the malleability and ductility of the metal. An alloy of 70 per cent. copper, 23 per cent. nickel, and 7 per cent. aluminium has a fine yellow colour, and takes a high polish. Alloys of zinc and aluminium are very brittle and crystalline. The best solder for aluminium is this alloy of zinc and aluminium, Venetian turpentine being used as a flux. It

does not flow very well, and the soldered surfaces will not withstand hard usage.

*Practical Hints.*—A number of instructions are given for working aluminium.

*Alloys of Aluminium and Copper.*—Ten per cent. aluminium with 90 per cent. copper (called 10 per cent. aluminium bronze) when rolled into plates has an elastic limit of 70,000 to 80,000 lb. per square inch, a tensile strength of from 100,000 to 120,000 lb. per square inch, a reduction of area of from 20 to 40 per cent., with an elongation of from 5—10 per cent. in eight inches. The metal has a beautiful yellow colour, and is capable of taking a high polish. It is unacted upon by dry or moist air. Its specific gravity in castings is 7.84, in rolled sheets about 7.89. Its modulus of elasticity is about 18,000,000 lb. In castings it has a tensile strength of between 70,000 and 80,000 lb. per square inch, with a reduction of area of about 20 per cent. Ten per cent. aluminium bronze melts at about 1,700° F., its melting point being a little higher than that of brass. It solidifies very rapidly and must be poured quickly. Care should be taken to prevent oxidation. Aluminium bronze is a very close-grained dense metal. It can be worked at a bright red heat and does not change at this temperature, hence it is well adapted for blast-furnace tuyères. It can also be remelted several times without loss, this property enabling scrap metal to be easily worked up. It can be brazed with a solder consisting of zinc and copper in equal proportions. One part of solder is used with three parts of a mixture of equal parts of borax and cryolite.

*Aluminium in Wrought Iron.*—Aluminium has been used with wrought iron in the well-known Mitis process for making castings in that metal.

*Aluminium in Cast Iron.*—The effect of aluminium on cast iron is to convert the combined carbon into graphite, thus changing white iron into grey. It has been used in proportions of  $\frac{1}{10}$  to 2 per cent. with good results.

*Aluminium in Steel.*—The effect of the metal on steel is to convert the combined carbon into graphite and to destroy the hardening action of the carbon in tool steel. In structural steel of .2 per cent. to 1 per cent. of carbon a small amount of aluminium increases the tensile strength without decreasing the ductility. When aluminium high in silicon is added to steel the silicon becomes converted into the amorphous form. It is frequently stated that aluminium lowers the melting point of steel and renders the steel more fluid and freer from blow-holes. It can be most advantageously used in proportions of from  $\frac{1}{10}$  to 3 per cent.

Methods of preparing alumina are given.—H. K. T.

#### *Use of Alloys in Metal Work.* W. C. Roberts-Austen. Soc. Arts J. 1890, 689.

THE subject of this paper is the colouring of metal-work, and its principal theme is the clever manner in which the Japanese impart a charming variety of colours and tints to bronzes and other metals by means of alloys and certain pickling solutions. They mix together copper, silver, gold, lead, and iron, and by varying the proportions of the different ingredients produce effects which are at once artistic and permanent. One of their chief mixtures is called "shaku-do," of which the analysis is as under:—

Copper .....	94.50
Silver .....	1.55
Gold .....	3.73
Lead .....	.11
Iron and arsenic .....	Traces
Total .....	99.89

Another analysis of this mixture shows:—

Copper .....	95.77
Silver .....	.08
Gold .....	4.16
Total .....	100.01

This mixture has been used by the Japanese for very large works, some of which, cast in the seventh century, are specially remarkable. Another important alloy is called "shibu-ichi," of which the following are said by Roberts-Austen to be typical analyses:—

Copper .....	67.31
Silver .....	32.07
Gold .....	Traces
Iron .....	.52
Total .....	99.90
Copper .....	51.19
Silver .....	48.93
Gold .....	.12
Total .....	100.15

The precious metals used in these mixtures vary considerably, but in the shaku-do the gold is made to yield a beautiful purple patina when treated with the pickling solutions, whilst the shibu-ichi possesses a very attractive silver-grey tint of its own. As to the pickling solutions the following are made up respectively as given here, and are used boiling:—

—	I.	II.	III.
Verdigris .....	438 grains	87 grains	220 grains
Sulphate of copper ..	292 "	437 "	540 "
Nitre .....	..	87 "	..
Common salt .....	..	146 "	..
Sulphur .....	..	233 "	..
Water .....	1 gall.	..	1 gall.
Vinegar .....	..	1 gall.	5 fl. drachms

The action of these solutions is said to be remarkable, especially in bringing out the tints and colours of which the Japanese workers in metals are so fond. The author, after enumerating some of these effects, asks, "Why cannot we in this country use the alloys named in order to produce similar results?" The question is quite pertinent and proper. We should be very pleased indeed if some of our gold and silver smiths, for instance, could see their way to following up, and possibly improving upon, the Japanese practice in these respects. Up to the present time only one English artist (Alfred Gilbert) has done anything of the kind, but the Americans and French have taken hold of the idea, and are working it already with conspicuous success. In Paris, Christoffe, and in New York, Tiffany, are producing beautiful pieces of work by using alloys, and the latter are even said to have discovered the secret of the celebrated Japanese "lobster red." What these firms can do we also ought to be able to perform, and as the abolition of the plate duties will be calculated to increase competition from without, it is absolutely necessary that our metal workers—of all grades—should bestir themselves in order to meet the threatened increase of rivalry from foreign and American houses. Roberts-Austen's elaborate explanation of Japanese work seems to us to offer an entirely new field to our artists and artisans. It is to be hoped that they will lose no time in making practical use of the information.

#### PATENTS.

*Improvements in Apparatus for Coating with Tin, Lead, or other Metals or Alloys.* H. F. Taylor, Neath. Eng.  
Pat. 6594, April 17, 1889. 11d.

THESE improvements relate to the cradle and nipping apparatus for immersing the plate to be coated, and refer especially to the coating apparatus described in Eng. Pat. 4350 of 1888. The nipper hook which seizes the plate is continuous with a tumbler or short lever having two faces

set at an angle. These faces come in contact with tappets which open and close the nipper hook as the cradle moves up and down, the plate being nipped between the nipper hook and cradle. In order to maintain the nipper hook in its open or closed position a rod is provided which is held in a yielding manner at its upper end, and whose lower end presses into a recess formed in the tumbler, and maintains the hook on one or the other side of its pivot centre.—H. K. T.

#### *Improvements in obtaining Alloys of Aluminium.*

G. Bamberg, London. Eng. Pat. 7666, May 8, 1889. 4d.

IRON or copper rich in carbon or silicon is introduced while in a molten condition into a Bessemer converter. The temperature is raised by blowing air through the metal in the usual way. Vapour of aluminium chloride or of the double chloride of aluminium and sodium are then introduced. Zinc or lead can be used instead of iron or copper.

—H. K. T.

#### *Improvements in obtaining Aluminium or its Alloys.*

G. Bamberg, London. Eng. Pat. 7667, May 8, 1889. 4d.

METALLIC zinc and aluminium chloride (or the double chloride of aluminium and sodium) are heated in separate retorts to a white heat, and the vapours produced are allowed to mix in a third retort or chamber also maintained at a high temperature. The zinc is used in excess. The resulting alloy of aluminium and zinc is heated to about 1,040 C. for the purposes of volatilising the zinc. (See preceding abstract.)—H. K. T.

#### *Improvements in the Production of Alloys of Aluminium.*

R. E. Green, London. Eng. Pat. 9358, June 5, 1889. 4d.

A MIXTURE of pig iron, aluminium fluoride, or cryolite and sand, silicate of potash, or "silicon disulphide" is heated in a crucible to a white heat until the silicon fluoride is driven off. The iron-aluminium alloy is then run into moulds.—H. K. T.

#### *Improvements in Apparatus for treating Metallic Ores or Compounds with Chemicals.*

S. Alley, Polmadie. Eng. Pat. 9592, June 11, 1889. 8d.

See under 1, page 726.

#### *Improvements in the Treatment of Zinc Ores.*

The Alkaline Reduction Syndicate, Limited, and A. B. Cunningham, Hebburn-on-Tyne. Eng. Pat. 9987, June 18, 1889. 4d.

ZINC ores containing silica and lead which have hitherto proved troublesome to smelt, are fused with caustic soda, the quantity required varying with the percentage of these impurities; e.g. an ore containing 30 per cent. of zinc and 30 per cent. of lead is treated with 50 per cent. of caustic soda. The lead is reduced to the metallic state and can be drawn off; it contains any silver or gold that may be present. The alkaline melt is lixiviated preferably by running it direct into water, the sodium silicate, sulphide, and excess of caustic soda being dissolved, and the purified "zinc-compound" left for reduction in the ordinary way, or for use after purification as a pigment. Iron and copper, if present in the original ore, remain in the treated ore, but do not hinder the reduction to metallic zinc. The alkaline liquor may be causticised with lime, the silica being thereby precipitated, concentrated and used again.—B. B.

#### *Improvements in the Manufacture of Copper Alloys.*

J. C. Bull, Belvedere. Eng. Pat. 10,154, June 21, 1889. 4d.

MAGNESIUM carbonate is mixed with carbonaceous matter and granulated copper, and the mass run down in a furnace,

an alloy of copper and magnesium containing about 2 per cent. of the latter metal being obtained. By repeating the process, using the product of the first melt instead of pure copper, an alloy containing about 6 per cent. of magnesium results. Suitable proportions are eight parts of copper, two of charcoal and four of magnesium carbonate. A preferable plan however is to use magnesium chloride as the source of magnesium. It is mixed with half its weight of common salt, to delay its decomposition until the melting point of the copper has been nearly reached, and the same quantity of quicklime, and the charge thus made gives an alloy containing as much as 5 per cent. of magnesium at the first melting, and 8 per cent. on repetition of the process.

Suitable proportions are eight parts of copper, two of carbon, two of magnesium chloride, one of common salt, and one of quicklime.

In both processes the temperature is kept as closely as possible below the melting point of the copper or alloy for one hour, the charge then melted and poured at the end of half an hour.—B. B.

#### *Improvements in the Wet Method of Extracting Gold and in Apparatus to be used therewith.*

J. H. Pollok, Glasgow. Eng. Pat. 10,298, June 25, 1889. 8d.

AFTER the ore has been treated with chlorine in the chlorination process, caustic or carbonated alkalis, or alkaline earths, or reducing agents which will absorb the chlorine without precipitating the gold, are added, thereby preventing the escape of noxious fumes. The charge is then drawn off and filtered and the filtrate is returned to the generator together with a fresh quantity of ore, a small quantity of bleaching powder and sufficient acid to liberate the whole of the chlorine. The process is repeated until the liquor is sufficiently rich in gold, which is then precipitated. A combined apparatus is described, consisting of a spherical generator and a filter bed connected by means of pipes and steam injectors with a series of vats. The same liquor is used repeatedly as above described, the washings from the ore being collected separately. The washings and concentrated gold solution are then mixed and the gold precipitated. (See this Journal, 1889, 444—446.)—H. K. T.

#### *Improvements in the Treatment of Gold and Silver Ores by the Hydro-metallurgical or Wet Method.*

J. Harper, London. Eng. Pat. 10,394, June 26, 1889. 8d.

THE ore is first roasted with salt and poor copper ore. It is then introduced into a chlorinator together with water or a solution of copper chloride, bleaching powder, and sulphuric acid. After a sufficient treatment the charge is transferred to a closed filter, air pressure being applied above, or suction below the filter. When the amount of gold in the ore is less than 1½ oz. per ton the treatment in the chlorinator is omitted. To the clear liquid from the filter sufficient calcium polysulphide is added to precipitate the gold and silver. The latter are filtered off and the filtrate is stored in a tank to be used again in a hot or cold condition in the first filter with a fresh quantity of ore. The filter beds are composed of layers of basket work, moss, pebbles, and coarse sand, the basket work being uppermost and the sand filling the interstices. A system of tanks and leaching vessels is described.

—H. K. T.

#### *Process for Removing Gases and Foreign Impurities from Metals or Alloys.*

J. L. Schenius, Stockholm, Sweden. Eng. Pat. 3440, March 4, 1890. 6d.

THE process is designed to increase the homogeneity of iron and other metals by subjecting them while fluid or semi-fluid to the action of "centrifugal force" in a "rotator." A machine adapted for this purpose consists essentially of a vertical shaft capable of being rotated, carrying a horizontal disc or radial arms at its upper end; from the edge of the disc or the ends of the arms moulds for receiving the molten metal can be hung so that when the whole is revolving they may fly out like the arms of a governor and eventually, when a sufficient speed is attained, become horizontal. By

this means the metal they contain is driven to the further extremity of the mould, while any lighter impurities, e.g. slag or gases, are forced to the near end, the metal thus gaining in homogeneity. In some cases the metal may be "centrifugalled" in the ladle before casting.—B. B.

*A Process for Concentrating Magnetic Iron Ore.* H. J. Haddan, London. From G. Conkling, Glensfalls, New York, U.S.A. Eng. Pat. 4690, March 25, 1890. 6d.

THE comminuted ore, suspended in water, falls vertically in contact with an endless band which moves in the opposite direction. Behind the endless band an electro-magnet is placed. The magnetic particles are attracted to the band. They are carried upwards and are scraped off into a suitable receptacle.—H. K. T.

*An Improved Process to be Employed for Hardening Steel.* J. H. Bramwell, Sheffield. Eng. Pat. 6529, April 29, 1890. 4d.

THE patentee hardens steel in a concentrated solution of common salt at a temperature of 100°–150° F., by immersion and agitation in the case of tools that are to be hardened uniformly, or by the local application of a stream of the liquid to such articles as are to be hardened in parts.—B. B.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### PATENTS.

*Improvements in Galvanic Cells.* R. A. Burnell, London. From T. Wilms, Hamburg, Germany. Eng. Pat. 6110, April 15, 1889. 8d.

THE cell is a modification of the ordinary Leclanché. The carbon is in the form of a large rod with deep longitudinal grooves. In one of these is placed a zinc rod suitably insulated; in the others are porous sheaths containing broken manganese peroxide. These sheaths project partly into the air to absorb oxygen for depolarising purposes and can be turned about in their grooves. For dry cells, a carbon of the same shape is used, but the manganese peroxide not only fills the grooves, but forms a layer all round. This layer is surrounded by absorbent material soaked with sal-ammoniac. A square perforated zinc tube encloses the absorbent material and is surrounded by more of the absorbed sal-ammoniac.—E. T.

*An Improved Exciting Liquid for Electric Batteries.* M. Süssmann, Berlin, Germany. Eng. Pat. 9183, June 3, 1889. 4d.

FERRIC chloride is used as an electrolyte with the addition of about 14 per cent. of zinc chloride, if zinc is the positive metal used. Without the chloride of the positive metal the current very rapidly falls off.—E. T.

*Improvements in Grids or Containers for the Elements or Plates of Secondary Batteries and Moulds to be Used in their Manufacture.* The Electrical Power Storage Co., Lim., and P. J. Rea, London. Eng. Pat. 9723, June 12, 1889. 8d.

THIS invention relates to moulds for the casting of secondary battery grids or containers, such that the active material contained shall not be liable to split or fall away. In the direction at right angles to the barrel section of the mould, the plug is further held by small projections cast

on the corresponding walls of the grid. Thus the active material is securely held even if it should split, which is not likely to occur. Moulds for various other sections of grid are described, the two parts of the mould, wherever under-cut sections are adopted, being separated in an oblique direction.—E. T.

*Improvements in Apparatus for Separating Gold and other Metals from their Ores by the Aid of Electricity.* G. J. Atkins, Tottenham. Eng. Pat. 10,061, June 19, 1889. 6d.

THIS invention is for improvements in the carbon screw anode of Eng. Pat. 12,295 of 1886. The screw sections are now fixed on a metal shaft, preferably of square section, by being threaded on into position, and having molten lead, type-metal, or other conductor cast in between the bosses of the sections and the shaft, good mechanical and electrical contact being thereby obtained to every section. Similar means are employed for fixing the shell form of anode. All the metal part of the apparatus is of course protected by insulating material, and the carbon part preferably impregnated with black earth-wax.—E. T.

*Improvements in the Manufacture of Sodium, Potassium, and Magnesium.* T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 11,707, July 23, 1889. 4d.

THE carbonates, hydrates, or oxides of sodium, potassium, or magnesium are mixed with a quantity of finely divided carbon sufficient to reduce them to the metallic state and heated by means of "an electric arc or electrical resistance," the metal volatilising and being condensed by suitable means. The electrodes used may be of iron, and a liquid bath of iron or other metal may be maintained at the base of the furnace for the purpose of diffusing the heat. The charge may be heated before introduction in order to economise current.—B. B.

*Improvements in Treating and Rectifying or Ageing Alcohol or Alcoholic Liquors or the like by Electricity.* A. de Méritens, Paris, France. Eng. Pat. 14,162, September 7, 1889. 4d.

See under XVII., page 758.

*Improvements in Electric Batteries.* C. Payen, Philadelphia, U.S.A. Eng. Pat. 18,481, November 19, 1889. 8d.

A CERTAIN amount of foreign material, such as zinc or cadmium, or their chlorides, is added to lead chloride, and the whole cast as a plate in a two-part mould. As the mass cools, crystals form and extend inwards from the edges. A metal supporting frame is then cast round the plate and the salts reduced by chemical action or by electrolysis. The foreign metal is removed in this reduction or by fusion, volatilisation, or sublimation, the plate being well washed afterwards. Such plates possess great porosity and conductivity. Instead of using the metal supporting frame, contact may be made by platinum strips cast into the plates.—E. T.

*Improvements in Electric Dry Batteries.* C. R. Bonne, London. From H. Meinecke, jun., Breslau, Germany. Eng. Pat. 19,129, November 28, 1889. 4d.

"The invention consists in saturating the carbon electrode in sulphate or nitrate of silver and in bringing it in contact with sal-ammoniac or with other liquid or substance saturated with liquid, in order to form chloride of silver, which is deposited in finely-disintegrated particles on the carbon. The intervening space between the zinc and carbon elements of the battery is filled with porous or absorbent material, to contain the sal-ammoniac or other liquid."

*Improvements in Electric Insulating Compounds.* J. B. Williams, Oakland, California, U.S.A. Eng. Pat. 1878, February 4, 1890. 6*d*.

AN insulating material for ordinary wires is made by mixing 60 parts by weight of india-rubber, 10 of a paraffin—preferably that obtained from ozokerite or mineral waste—22 of shellac, and 8 of sulphur. For a harder material for stationary conductors, inert material, such as silica, or a bituminous material that is solid and brittle when cold, may be added up to 30 per cent., or to 50 per cent. for telegraph insulators, &c. The amount of india-rubber may be varied, according to the degree of flexibility desired. The india-rubber is dissolved in "benzole" or other volatile solvent, the paraffin added and melted in; the solvent is distilled off, and the other ingredients incorporated with the help of steam rollers. Vulcanisation may be resorted to if desired, but is not considered so good.—E. T.

*Improved Storage or Secondary Batteries.* W. B. Hollingshead, East Chester, N.Y., U.S.A. Eng. Pat. 3008, February 25, 1890. 6*d*.

THE two electrodes are of iron and manganese peroxide respectively, the electrolyte being potassium bichromate, permanganate or cyanide, or other suitable solution. In charging, the peroxide is reduced to a lower oxide by hydrogen, and the iron oxidised. With bichromate electrolyte, chromic anhydride is deposited on the iron, and caustic potash is produced at the other electrode. The electrodes may be rods, or granules suitably encased.—E. T.

*Improvements in Storage or Secondary Batteries.* C. J. Hartmann, New Jersey, U.S.A. Eng. Pat. 3013, February 25, 1890. 8*d*.

IN one method of construction, each electrode is made up of three parallel and similar lead sheets, separated by a short distance from each other, the spaces between them being packed with the active material. To increase the surface, pockets of the shape of step pyramids are stamped in each plate in exactly similar positions, so that the pockets of A project into the inside of those of B. Holes are punched all over the surface of each sheet by a sharp tool, so as to leave a considerable burr. In another construction, the outside sheets are merely furnished with small corrugations, and are joined at the sides, so as to form a rectangular case. The central sheet is, however, furnished, in addition, with much larger corrugations, so that it consists of corrugated sheet made from metal already finely corrugated. Each sheet is here also covered with burr holes. The active material is either packed into the plates in a dry condition, or after mixing with gum or rosin made semi-fluid by an alkali. The plate is placed in an acid bath, which neutralises the alkali, and leaves the active material in a highly spongy condition.—E. T.

*Improvements in Secondary or Storage Batteries.* S. C. C. Currie, Philadelphia, U.S.A. Eng. Pat. 3439, March 4, 1890. 8*d*.

THE metallic portion of each electrode consists of a frame like an ordinary grid, with the top and all the meshes cut out, the sides, however, being farther apart at the top than at the bottom. A slab of active material is placed in this frame from the top and retained by its V-shaped edges, which fit into corresponding grooves in the two sides of the frame. India-rubber bands are placed vertically round the whole, and act as separators besides keeping the whole plate together. By drawing the bands to one side, the slabs can be drawn vertically out of the frames without disturbing the rest of the plates. A second frame of ebonite is sometimes placed outside the metal one.—E. T.

*Improvements in and Relating to Electric Secondary Batteries or Accumulators.* H. H. Lake, London. From T. Ewing, New York, U.S.A. Eng. Pat. 3455, March 4, 1890. 8*d*.

EACH plate is built up of a series of narrow strips of lead, one above another, each bent to the shape  indicated, the whole being suitably bound round. Each plate is supported on a strip of hard rubber of the same length and width as the plate, and furnished with short legs to enable the liquid to circulate under it. Vertical separating rods are employed, all the plates being bound together by horizontal belts of hard rubber, passing through both separators and plates. The lead oxide or other material is first mixed with sulphuric acid or other agent that will cause it to expand as much as possible; it is then heated to expel moisture, pulverised, and packed into the plates.

—E. T.

*An Improved Electrolytic Solution for Galvanic Batteries.* L. Weigert, Berlin, Germany. Eng. Pat. 3717, March 8, 1890. 4*d*.

CELLS containing the chlorides of iron, copper, &c., are known to be inconstant owing to the formation of insoluble salts. To remedy this defect the inventor adds oxidising agents, such as hypochlorites, to saturated solutions of the above mentioned salts. These agents are further said to have a regenerating effect on the electrolyte, and the cell can be made up as a single fluid one.—E. T.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

*On the Examination of Wax.* H. Rottger. Chem. Zeit. 14, 606—607.

See under XXIII., page 774.

*The Melting and Solidifying Points of some Fatty Bodies and Mixtures.* A. Terceil. Bull. Soc. Chim. 1890, 3, 195—200.

FOR the determinations given in the table below, there was used a specially constructed thermometer, graduated to half a degree, with a comparatively large flat bulb of the following dimensions: length 20 mm., width 10 mm., and thickness 5 mm. The fatty substances were melted and small portions transferred on the tip of a fine glass stirring-rod to the flat surface of the bulb. The thermometer was then heated. It was observed that on re-heating the thermometer, higher melting points were obtained than in the first determinations, in consequence of the imperfect adherence at first of the fatty matters to the glass; the points of solidification, on the other hand, were invariable. The fatty bodies examined were all carefully filtered, whilst hot, through paper, and dried for several hours at 110°—120°.

With regard to the results obtained, it will be observed, in the latter part of the table, that the melting and solidifying points of mixtures do not in any case correspond with the mean of the melting and solidifying points of the individual fatty matters present, but are invariably much higher, this being especially the case when one of the substances present melts and solidifies at a high temperature. Further, when oleic acid, petroleum, or paraffin enter into the composition of a mixture, its melting and solidifying points are lower than when neutral fats alone are present, but are still above the mean.

The results obtained are shown in the following table:—

	Parts.	Melting Point.	Commence-ment of Turbidity.	Solidifi-cation Point.

E. B.

*Linoleic Acid.* A. Reformatzky. J. prakt. Chem. 1890, **41**, 529—551.

THE author, after a résumé of the work already done on the subject, describes the method of research adopted by him. Linoleic acid was prepared by the method given by Schüler in 1857 (*Annalen*, **101**, 252—256). Fresh cold-pressed linseed oil prepared in the laboratory was saponified with caustic soda, salted out, redissolved, and precipitated by calcium chloride. The lime soap thus obtained was extracted with ether, in which calcium linoleate is soluble, and the ethereal solution treated with hydrochloric acid freeing the fatty acid, which was then purified by separating and washing its ethereal solution and distilling off the solvent. An ultimate analysis having shown the product to be impure, it was neutralised with ammonia and precipitated with barium chloride, and the barium salt treated by the process given above for the calcium salt, save that the final distillation was performed in an atmosphere of carbon dioxide. The

results being still unsatisfactory, the acid was distilled at  $292^{\circ}\text{C}$ . under a pressure of 100 mm., but the distillate on analysis gave numbers corresponding to no probable formula. Norton and Richardson (Ber. 20, 2735) and Hazura and Grüssner (Ber. 21, 436; this Journal, 1888, 506), have obtained by similar treatment products differing from this and from each other, so that the matter is still obscure. Another attempt was made to prepare pure linoleic acid by exposing the crude fatty acids from commercial linseed oil to cold, and purifying the still fluid portion by means of its barium salt. The product, however, yielded much dihydroxystearic acid on oxidation with permanganate, pointing to the presence in it of a considerable amount of oleic acid, and the method was abandoned. Ethyl linoleate was then prepared by acting on an alcoholic solution of crude linoleic acid, with gaseous hydrochloric acid. After washing with water any unacted-on linoleic acid was removed by washing with 80 per cent. alcohol, the product washed once more with water and distilled at  $270^{\circ}$ – $275^{\circ}\text{C}$ . at a pressure of 180 mm., by which process an almost colourless liquid, with a faint yellow tone, was obtained. It was mobile, slightly fluorescent, and possessed of a smell at first pungent but afterwards fairly pleasant; its specific gravity at  $20^{\circ}\text{C}$ ., compared with that of water at  $4^{\circ}\text{C}$ ., was 0.8865. The substance is fairly stable, altering only slowly in air, and its composition was proved by its ultimate analysis giving numbers very fairly agreeing with those required by the formula—

Bromine acted on it, giving a substance melting at  $178^{\circ}\text{C}$ ., apparently a hexabromide; an oily product was also formed.

Linoleic acid was obtained by saponifying the ethyl linoleate thus prepared, acidulating with sulphuric acid, and shaking out with ether; the ethereal solution left on evaporation a brownish mobile odourless oil, which, when dried in a vacuum receiver over sulphuric acid lime and ferrous sulphate, grew darker in shade. Analysis gave (1) carbon = 76.47 per cent.; hydrogen = 11.16 per cent.; (2) carbon = 76.36 per cent.; hydrogen = 11.10 per cent.; instead of carbon = 77.14 per cent.; hydrogen = 11.43 per cent., corresponding with the formula,  $\text{C}_{18}\text{H}_{32}\text{O}_2$ . This result was confirmed by the iodine number (determined by Bültz's modification of Hübl's method (J. prakt. Chem. 1888, 39, 82), the values found being 172.65 and 180.30, instead of 181.43 calculated for  $\text{C}_{18}\text{H}_{32}\text{O}_2$ , and by the analysis of the zinc salt, that being the most stable of those prepared. A final reason for believing linoleic acid to have the formula  $\text{C}_{18}\text{H}_{32}\text{O}_2$ , and not  $\text{C}_{16}\text{H}_{28}\text{O}_2$ , is found in its yielding stearic acid and not palmitic acid when hydrogenised. By long continued heating in a sealed tube with fuming hydriodic acid a product containing iodine corresponding with the formula  $\text{C}_{18}\text{H}_{33}\text{O}_2\text{I}$  was obtained, which on saponification gave an acid which melted at  $70^{\circ}\text{C}$ ., solidified at  $67^{\circ}\text{C}$ ., and gave numbers on analysis of its sodium and silver salts proving it to be stearic acid. Hydrochloric acid acts on linoleic acid even more slowly than hydriodic acid, not even so much being absorbed as corresponded with the addition product—

Linoleic acid when dissolved in glacial acetic acid and treated with bromine in the cold yields two bodies—

the former being a viscid oil, the latter a crystalline solid melting at  $177^{\circ}$ – $178^{\circ}\text{C}$ ., and solidifying at  $175^{\circ}\text{C}$ .

On oxidation with potassium permanganate in dilute alkaline solution according to the method of Saytzeff, (this Journal, 1888, 506) linoleic acid yields tetrahydroxystearic acid  $\text{C}_{18}\text{H}_{36}\text{O}_6$ , as the main product, azelaic acid,  $\text{C}_9\text{H}_{16}\text{O}_4$ , being formed in smaller quantity as well as a little formic acid.

The composition of the drying oils as determined from the products which they yield on oxidation with potassium permanganate in alkaline solution, is a matter still in dispute between the author and Hazura. The researches of the latter, alone and in conjunction with other chemists, have led to the belief that small quantities of linolic and isolinolic acids (this Journal, 1888, 506) are formed. The author

considers that their formation is not characteristic, but is due to some secondary reaction governed by alterations in the conditions of oxidation. He also doubts their being hexahydroxy acids and prefers to regard the substance he obtained as an anhydride derived from two molecules of tetrahydroxystearic acid. The conclusions which are finally arrived at are that the formula for linoleic acid is not  $\text{C}_{16}\text{H}_{28}\text{O}_2$ , but  $\text{C}_{18}\text{H}_{32}\text{O}_2$ , and that the hypothesis that it contains two doubly-linked atoms best explains its reactions.

—B. B.

## PATENTS.

*Improvements relating to Toilet and Cleansing Soaps.* J. Snowden, London. Eng. Pat. 9201, June 5, 1889. 4d.

TEX to 20 per cent. of the finer kinds of asbestos in a fibrous or pulverulent form are incorporated with toilet soaps, and 20–25 per cent. of the coarser varieties with industrial or domestic soaps, the product being termed "Amianthine soap."—B. B.

*Improvements in the Manufacture of Soap and Glycerin.* J. Y. Johnson, London. From M. Duclos, Paris, France. Eng. Pat. 4809, March 27, 1890. 4d.

IN order to obtain the glycerol resulting from the saponification of fats in the ordinary course of soap-making free from the alkaline salts that accompany it when it is recovered by merely boiling down the spent lyes, the patentee saponifies his material with milk of lime (1 of quicklime to 10 of water), effecting his purpose by sufficient dilution and vigorous boiling by open superheated steam, without having recourse to the use of excess of lime (14–15 per cent. instead of the 10 per cent. he employs) or of pressure, as in the autoclave process. An acid lime soap is formed, and the liquor separated from it together with the washings contain almost the whole of the glycerol, which can be obtained of good quality simply by evaporation. The lime soap is decomposed by sulphuric or hydrochloric acid, and the freed fatty acids, which are of good quality, used for making soap in the ordinary way.—B. B.

## XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

### PATENTS.

*An Improved Preservative and Waterproof Coating for Metals, Timber, Masonry, Concrete, or other Structures or Surfaces.* T. Pridham, Petersham, New South Wales. Eng. Pat. 18,286, November 15, 1889. 4d.

A MIXTURE of or containing mineral bitumen and oil or oily materials, rolled or pressed into sheets, applied to the article to be covered by an adhesive solution.—E. G. C.

*Improvements in Electric Insulating Compounds.* J. B. Williams, Oakland, California, U.S.A. Eng. Pat. 1878, February 4, 1890. 6d.

See under XI., page 743.

#### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

*On the Oxidation of Gallic Acid, Tannin, and Quercitannic Acid.* C. Boettinger. *Annalen*, **257**, 248—252.

WHEN gallic or tannic acid is oxidised with nitric acid of moderate dilution, oxalic acid is the chief product; if this be removed by crystallisation and lime added to the residue free from nitric acid, there are formed two lime salts besides the oxalate, one difficultly and the other easily soluble in water. Gallic acid yields only a very little of the first and tannin only a small quantity of the same; the analytical numbers agree with those of calcium trioxylglutarate. The easily soluble lime salt is calcium trioxylbutyrate. By using more nitric acid easily soluble calcium salts may be obtained containing 15—16 per cent. of calcium.

In the same way the acetyl derivative of quercitannic acid yields on oxidation oxalic acid and two acids which form respectively a difficultly soluble and an easily soluble calcium salt. The first is trihydroxyglutaric acid and the second trioxylbutyric acid; by using larger quantities of nitric acid other acids may be obtained which yield salts containing more calcium. (See also this Journal, 1890, 84).—A. L. S.

#### XV.—AGRICULTURE, MANURES, Etc.

*Determination of Nitrogen in Manures.* E. Anbin and J. Quenot. *Bull. Soc. Chim.* 1890, **3**, 322—326.

See under XXIII., page 773.

*Destruction of Clover Silk by Iron Sulphate.* Boiret. *Jour. d. Agric.* 1889, **2**, 779—782. P. Marguerite-Delacharlonny. *Ibid.* 1890, **1**, 182—187.

BOIRET expressed unfavourable opinions with regard to the statements:—that ferrous sulphate killed clover silk without injury to the clover plant; that the composition of

the soil had any influence on the action of ferrous sulphate on plant life, and that mowing clover plants stricken with clover silk was of any use either before or after use of ferrous sulphate. All these opinions Delacharlonny shows to be unfounded and unsupported by scientific evidence, and then summarises the results of his own investigations. He points out that ferrous sulphate is admirably adapted for the extinction of clover silk in all stages of development; that for young clover plants it should be used in the solid form in quantities of from 300 to 400 kilos. per hectare; that in cases where the clover silk has attained complete development the clover plants should be cut down and removed, and then the stubble should be dressed with ferrous sulphate solution varying in strength from 4 to 10 per cent. according to the age of the plant and the composition of the soil, using weak (4 to 5 per cent.) solutions on clayey and sandy soils, and strong ones (10 per cent.) on calcareous land.

Finally, it is considered advisable to dress the cut clover with the same solution before removal, to prevent the spread of the parasite.—D. A. L.

*Tobacco Experiments.* Kentucky Agricultural Experiment Station Bulletin, **28**.

THE experiments covered one acre consisting of one-tenth acre plots. The nature of the soil has been already described (*Bulletin*, **26**, 1; also this Journal, 1889, 555). The land had been in cultivation for many years, and had never been fertilised till spring 1888, when 100 lb. each of acid black (waste bone black treated with oil of vitriol), potassium chloride and sodium nitrate were mixed and sown broadcast over the plot.

1. *The Effect of the Leading Elements of Plant Food on the Production of Tobacco.*—The "leading elements of plant food" are potash, nitrogen, and phosphoric acid.

Two series of experiments were tried; in the first the plots were one-twentieth acre, and in the second one-fortieth acre. In both series the fertilisers were sown broadcast just before the plants were set. The plants were set 22 inches apart in rows 3 ft. wide. Tables are given showing the results of each series; as those of the second series are similar to those of the first, the table showing the latter need only be transcribed. The last column shows the total yield calculated to a perfect stand, i.e. the yield which would have been produced if every plant which was set had succeeded.

No. of Plot.	Fertiliser used.	Amount of Fertiliser. Pounds per Acre.	Yield in Pounds per Acre.						Total Actual.	Total Corrected.
			Bright.	Red.	Lugs.	Tips.	Trash.			
1	Sodium nitrate . . . . .	160	230	450	310	90	530	1,610	1,710	
2	Acid phosphate . . . . .	320	..	490	450	70	490	1,110	1,140

3. *In what Form should Nitrogen be applied?*—Sodium nitrate, ammonium sulphate, and cotton-seed meal were the three forms of nitrogen tried, and they were applied in quantities such that each plot received the same amount of nitrogen. The results were as follows:—

[illegible]

4. *In what Form should Potash be applied?*—It is generally believed that potassium chloride is injurious to the quality of tobacco, especially smoking tobaccos, and therefore sulphate is generally considered to be the best form for this crop. Both were tried with the following results:—

[illegible]

5. *The Amount of Nitrogen required per Acre.*—From the results of the experiments having this object it would seem that 160 lb. of sodium nitrate or 340 lb. of cotton-seed meal or rather more than 120 lb. of ammonium sulphate would furnish nitrogen in sufficient quantity for the crop.

6. *The Amount of Potash Fertiliser required per Acre.*—The experiments detailed in the above table serve to show that rather more than 160 lb. of either sulphate or chloride of potassium would be beneficial to the crop.

The conclusions to be drawn from these experiments are (1) that commercial fertilisers materially increase the yield, and improve the quality of Burley tobacco; (2) that the increase is obtained whether potash, phosphoric acid, or nitrogen is used separately or in various combinations; (3) that potash and nitrogen in combination seem to be required to produce the best results; (4) that there is a handsome profit by using fertilisers in the best combinations; (5) that the effect is the same whether potash is used in the form of chloride or sulphate; (6) that nitrogen in the form of nitrate of sodium seems to produce the best results as to quality.—A. G. B.

## XVI.—SUGAR, STARCH, GUM, Etc.

*Experiments on Gum Arabic and Gum Senegal.*  
L. Liebermann. Chem. Zeit. 14, 665—666.

See under XXIII., page 770.

*On the Isolation of Crystallised Cane Sugar from Maize.*  
J. H. Washburn and B. Tollens. Annalen, 257, 156—160.

MAIZE is ground and extracted with 72 per cent. alcohol containing a little lime, in order to destroy all acids, soluble ferments, &c., which might invert the cane sugar. The extract is distilled and the residue treated with water and one-third ether. The aqueous extract is evaporated to a syrup, this is dissolved in three or four times its weight of water, 20 per cent. alcohol added, and an excess of crystallised strontium hydroxide. The whole is boiled 5—10 minutes, and the excess of strontium hydroxide and the precipitate quickly filtered out and washed with alcohol. This is then suspended in water and carbon dioxide passed through until the liquid is nearly neutral. The filtrate from this is evaporated and the strontium compound precipitated with one-fourth to one-fifth its volume of alcohol. This is suspended in water, the strontium removed by carbon dioxide, and the filtrate treated with animal charcoal and evaporated. The syrup thus obtained will either crystallise spontaneously or after the addition of a little alcohol. The crystals have all the properties of cane sugar, and are undoubtedly this body.

The authors have made complete analyses of American sweet maize in various stages of growth, and among other factors they have determined the amount of nitrogen-free extract, and they find that besides starch, cane sugar, dextrin, glucose, this includes a non-crystallisable body which does not reduce Fehling's solution, not even after treatment with hydrochloric acid.—A. L. S.

*On the so-called Bi-Rotation of the Sugars.* E. Parcus and B. Tollens. Annalen, 257, 160—178.

THE authors have prepared solutions of most of the crystallised sugars which show bi-rotation, and determined the optical activity as soon as possible after solution and the rate at which the activity decreases or increases to the constant value. The solutions were in all cases, except lactose, 10 per cent. in strength; the observations were made in a 20 cm. tube, which was kept at a constant temperature of 20° C. by a water jacket. The chief results are epitomised in the following table; the time is taken from the moment

of addition of the water to the finely-powdered sugar. As complete solution takes quite an appreciable time, these times do not represent the absolute age of a freshly prepared solution.

*Dextrose.*—Greatest angle observed  $[\alpha]_D = +105.16$  in  $5\frac{1}{2}$  minutes, constant value of  $[\alpha]_D = +52.5$  in 6 hours.

*Galactose.*—Greatest angle observed  $[\alpha]_D = +147.48$  in 7 minutes, constant value of  $[\alpha]_D = +80.3$  in 6 hours.

*Lactose.*—Greatest angle observed  $[\alpha]_D = +82.91$  in 8 minutes, constant value of  $[\alpha]_D = +52.53$  in 24 hours.

*Arabinose.*—Greatest angle observed  $[\alpha]_D = +156.65$  in  $6\frac{1}{2}$  minutes, constant value of  $[\alpha]_D = +104.6$  in  $1\frac{1}{2}$  hours.

*Maltose.*—Angle observed  $[\alpha]_D = +118.75$  in 6 minutes, constant value of  $[\alpha]_D = +136.8$  in 5 hours.

*Xylose.*—Greatest angle observed  $[\alpha]_D = 78.61$  in  $4\frac{1}{2}$  minutes, constant value of  $[\alpha]_D = +19.2$  in  $2\frac{1}{2}$  hours.

*Leucrose.*—Greatest angle observed  $[\alpha]_D = -104.02$  in 6 minutes, constant value of  $[\alpha]_D = -92.1$  in 35 minutes.

Other determinations of the constant value for the last sugar gave  $[\alpha]_D = -92.25$  as the mean.

The authors calculate that at the moment of solution the optical activities are, for xylose  $[\alpha]_D =$  above 100, for arabinose about 190, for galactose about 127, and for leucrose above 100. They take objection to the term bi-rotation, as only in the case of dextrose is the maximum activity double the normal, and suggest the terms more-rotation and less-rotation.—A. L. S.

*Action of Lime on Raffinose.* L. Lindet. Bull. Soc. Chim. 1890, 3, 413—414.

ONLY one compound of lime with raffinose exists; 100 parts of raffinose combine with 10 or 11 parts of lime. The solution of this compound does not become turbid on boiling, differing in this respect from calcium saccharate. At a given temperature raffinose dissolves less lime than cane sugar; thus, at 15°, a 12 per cent. solution of raffinose hydrate dissolves 11.58 per cent. of CaO, a similar solution of cane sugar dissolving 25.42 per cent. Again, a 4 per cent. solution of raffinose dissolves 10.14 per cent. of CaO, whilst cane sugar, under the same conditions, dissolves 21.80 per cent. of the same. Calcium raffinolate, like calcium saccharate, is precipitated by alcohol, but is less soluble in this liquid than the latter. The author attempted to base on this circumstance a process for the fractional separation of the two sugars. A sample of molasses from a sugar refinery was mixed with alcohol so that the mixture contained 50 per cent. of alcohol, and then lime was added in fractions. The compositions of the precipitates obtained were as follow:—

	Raffinose.	Cane Sugar.
	Per Cent.	Per Cent.
1st fraction	20.0	80.0
2nd fraction	18.1	81.9
3rd fraction	15.8	84.2
4th fraction	12.3	87.7

—E. B.

*The Action of Mineral Acids on Saccharification by Means of Malt, and on the Fermentation of Starchy Substances.*  
J. Effront. Monit. Scient. 1890, 449—462.

DURING the saccharification of starchy substances on the large scale in distilleries and breweries, the activity of the diastase is greatly checked by the growth of objectionable organisms, especially the lactic and butyric ferments. The growth of these organisms may be checked by the use of

high temperatures or by the addition of mineral acids. The first method is scarcely admissible, for the temperatures most suitable to diastatic conversion—50° to 60° C.—do not check the development of the false ferments. On the other hand, the author considers the use of mineral acids more rational. It is well known that acids in comparatively small quantities retard or completely arrest the lactic and butyric fermentations; and, according to Delbrück, a small amount of acid also accelerates the action of the diastase. The

author has made numerous experiments in order to determine the precise effect of small quantities of different acids on the lactic and butyric ferments, on diastase, and on yeast. A solution of commercial maltose was prepared of 7° Balling. To separate portions, small amounts of hydrofluoric, hydrochloric, and sulphuric acids were added.

The mixtures were then caused to enter into lactic fermentation at the most suitable temperature. The following results were obtained:—

Number of the Experiment.	Acid used.	Quantity added to 100 cc. of Wort.	Lactic Acid formed per 100 cc. of Wort.			
			24 Hours.	3 Days.	7 Days.	10 Days.
1	..	Mgrms. 0	Mgrms. 190	Mgrms. 453	Mgrms. 493	Mgrms. 828
2	HF	2	133	331	507	540
3	..	3	54	153	315	460

5	..	25	..	..	..	..
6	HCl	10	135	378	450	720
7	..	20	90	360	360	450
8	..	80	22	45	63	81
9	..	200	..	..	..	..
10	H <sub>2</sub> SO <sub>4</sub>	10	144	132	468	765
11	..	20	108	414	522	549
12	..	80	36	81	90	99
13	..	200	9	18	36	43
14	..	300	..	..	..	..

The results show that hydrofluoric acid acts much more energetically than the other two acids. A peculiarity about its action is that it is considerably more vigorous during the first 24 hours than it is later on. The effect of these

acids on the butyric fermentation is very similar to the above. In the case of a mixed lactic and butyric fermentation, the following results were obtained:—

#### THE ACTION OF HYDROFLUORIC ACID ON A SIMULTANEOUS LACTIC AND BUTYRIC FERMENTATION.

Number of the Experiment.	Acid added to 100 cc. of Wort.	Total Acid formed per Litre of Liquid.				Butyric Acid.	Butyric Acid per 100 of Total Acid.
		24 Hours. cc. of N.NaHO per Litre.	Two Days. cc. of N.NaHO per Litre.	Three Days. cc. of N.NaHO per Litre.	Four Days. cc. of N.NaHO per Litre.		
1	Mgrms. 0	24	40	56	57	Mgrms. 431	Mgrms. 8'5
2	1	18	30	42	54	352	8
3	2	12	30	37	39	248	7'1
4	3½	7	12	27	30	220	8'3
5	1½	6	11	20	30	176	6'6
6	5	6	10	23	25	132	6
7	5½	5	10	22	23	88	4'3
8	6	5	8	16	24	12	0'62
9	7	4'8	9	13	20	8	0'5
10	8	1'8	4	5	9	8	..
11	10	1	1'5	1'5	3	..	..
12	20	0'3	0'5	0'5	0'5	..	..

The butyric acid was determined after the fourth day of acidification. The total acidity is expressed by the volume of normal soda required to neutralise it; and in the column headed "Butyric acid," the quantity of that body per litre is given. Butyric acid, even in small quantity, considerably

retards the growth of yeast and the yield of alcohol. Lactic acid, on the other hand, seems to act favourably in these respects. Hydrochloric and sulphuric acids behave very similarly to hydrofluoric acid, except that considerably more of them is required to produce a given effect.

It now became necessary to determine whether the small doses of acid added had any deleterious action on the activity of the diastase. For this purpose a cold water extract of green malt was prepared and portions of it were treated with different amounts of hydrofluoric acid, and

heated for seven days to 30° C. At regular intervals, small quantities were withdrawn, allowed to act on starch-paste at 55° C., and the maltose formed determined.

The results are given in the table below:—

No.	Acid added to 100 cc.	At Beginning.		Second Day.		Third Day.		Fourth Day.		Seventh Day.	
		Maltose per 100 cc.	Sacchari-fying Power of the Diastase.	Maltose per 100 cc.	Sacchari-fying Power of the Diastase.	Maltose per 100 cc.	Sacchari-fying Power of the Diastase.	Maltose per 100 cc.	Sacchari-fying Power of the Diastase.	Maltose per 100 cc.	Sacchari-fying Power of the Diastase.
1	0	2.76	100	1.89	68	1.59	57	0.32	12	..	..
2	2	2.73	99	2.55	85	2.32	84	0.7	25	0.57	20
3	3	2.76	100	2.30	87	2.38	87	1.08	40	0.83	30
4	5	2.78	101	2.57	93	2.47	89	1.38	50	1.14	41
5	7	2.88	101	2.61	95	2.53	91	2.21	80	1.18	45
6	10	2.85	103	2.22	80	1.87	68	1.37	50	1.21	44
7	13	2.79	101.08	1.80	65.2	1.77	64	1.23	45	1.23	45
8	15	2.73	99	1.77	64	1.71	62	1.20	44	1.14	41
9	20	2.37	86	1.83	66	1.41	51	0.87	32	0.81	29
10	25	2.34	85	1.74	63	1.38	50	..	..	..	..

All the experiments were carried out under precisely the same conditions. The quantity of maltose formed in the first experiment was taken as a standard and called 100.

From the above results it will be seen that hydrofluoric acid favourably influences the preservation of diastase, and that 7 mgrms. per 100 cc. is the most suitable quantity to use. This amount, however, is not sufficient to check entirely the growth of lactic and butyric ferments; and, on reference to the first table, experiment 5, it will be seen that 25 mgrms. are required for this purpose. Hydrochloric and sulphuric acids in small doses at first exalt the activity of the diastase; but later on they exert a decidedly retard-

ing influence and, therefore, become objectionable. In the above experiments the malt extract was separately heated with the acid, and the small portion of this malt extract subsequently allowed to act on starch-paste would contain only a trace of acid. Further experiments were therefore made to determine the effect of acid on the actual course of the saccharification. To each of several portions of starch-paste (200 cc.) were added 20 cc. of cold water extract of malt, and small quantities of acid. The solutions were then heated for 2½ hours at 55° C. The following results were obtained:—

Number of Experiment.	Name of Acid.	Quantity added to 100 cc. of Solution.	Maltose.	Saccharifying Power of the Diastase.
1	.. .. .	Mgrms.	5.1	100
2	Hydrofluoric acid .....	1.5	5.28	103

15	" .. .. .	20	4.02	79

The normal saccharifying power of diastase, expressed by 100, corresponds to 5.1 grms. of maltose per 100 cc.

obtained in the first experiment. These results show us that the quantities of mineral acids necessary to arrest

lactic and butyric fermentation have an unfavourable action on diastase at 55° C. Their use is, therefore, inadvisable under these conditions. The influence of hydro-

fluoric acid on diastatic conversion at 30° C. was next determined, the results obtained being as follows:—

Number of Experiment.	Acid added to 100 cc.	After 15 Hours.		After 32 Hours.		After 72 Hours.	
		Maltose per 100 cc. of Solution.	Maltose per 100 of Starch Transformation Products.	Maltose per 100 cc. of Solution.	Maltose per 100 of Starch Transformation Products.	Maltose per 100 cc. of Solution.	Maltose per 100 of Starch Transformation Products.
1	Mgrms. 0	3.80	69.50	4.08	74.50	4.06	74.31
2	1.5	3.78	69.50	4.16	75.85	4.17	75.82
3	2	3.82	69.48	4.24	77.15	4.22	77.25
4	2.5	3.88	70.91	4.21	77.25	4.27	77.41
5	5	4.08	74.51	4.32	78.40	4.51	81.93
6	7	4.06	74.10	4.29	78.10	4.92	82.85
7	10	3.86	69.48	4.48	81.92	5.15	93.12

9	25	2.45	45.20	2.44	45.10	2.44	45.30
10	40	1.84	33.96	..	..	..	..
11	50	1.25	21.60	..	..	..	..

These results show that by the use of 7—10 mgrms. of hydrofluoric acid per 100 cc., a high degree of saccharification is obtainable.

Similar experiments were made with hydrochloric and sulphuric acids. The increase in the yield of maltose was very slight, and not to be compared with that produced by hydrofluoric acid. A similar series of experiments was made with a wort prepared from maize, since raw grain is more likely to be used in practice than pure starch. Four

kilos. of maize were heated for two hours under a pressure of three atmospheres, with about 15 litres of water. The mash was then cooled to 30° C. and mixed with malt extract. Different portions of the mixture were then treated with hydrofluoric acid, and kept at 30° C. for three days. Portions of the solutions were filtered and analysed at the end of 24 and 72 hours. The results are given in the following table:—

Number of Experiment.	Acid added to 100 cc.	After 24 Hours.			After Three Days.			
		Dry Matter per 100 of Solution.	Maltose per 100 of Solution.	Maltose per 100 of Dry Matter.	Dry Matter per 100 of Solution.	Acid per 100.	Maltose per 100 of Solution.	Maltose per 100 of Dry Matter.

The numbers in the column marked "Acid per 100" represent the number of cubic centimetres of normal soda required to neutralise 100 cc. of the liquid. In the case of the first experiment the liquid after three days' reaction gave a blue colour with iodine. Under the same conditions 2—5 were coloured red, whilst the rest yielded no colour with iodine. A glance at the column headed "Dry Matter" shows that the liquefying power of the diastase increases

with the quantity of acid employed. The solution in experiment No. 11 was fully analysed and found to contain besides the maltose, 1.27 of dextrin and 0.571 of other substances. This corresponds to a yield of 86.79 of maltose per 100 parts of starch transformation products. Another experiment with maize gave even better results, yielding 96 per cent. of maltose and 4 per cent. of dextrin. These results show that the current notions regarding the most

suitable temperatures for diastatic conversion are a little incorrect. It is generally considered that the best conversion is obtained between 50—60 °C., but the above experiments prove that the highest yield of maltose is got at 30 °C. by using hydrofluoric acid. The vigorous diastatic action is no doubt due to the fact that the acid used almost entirely checks the butyric and lactic ferments, so fatal to diastase.

—H. T. P.

*Diastase considered as a Mixture of Maltase and Dextrinase.* H. P. Wijsman, jun. Rec. des trav. Chim. des Pays-Bas. 1890, 9, 1.

THE author has attempted to determine whether diastase of malt consists of two different enzymes or not. He explains the transformation of starch by the action of two enzymes; one, *maltase*, which converts starch into maltose and erythro-dextrin, and the other *dextrinase*, which converts starch into malto-dextrin; erythro-dextrin being further acted on by *maltase* and converted into aerodextrin and maltodextrin being converted by *maltase* into maltose. In order to prove this he adds to a gelatin solution some of Lintner's soluble starch; this yields on cooling a solid transparent jelly. This is cut into thin sheets and small quantities of diastase placed on them. If then these sheets are placed in iodine solution the gelatin is coloured dark blue; in the diffusion field of the diastase there is formed a colourless ring and around this a violet ring. The colourless spot is where both enzymes have acted, the violet ring where the *maltase* alone has diffused and acted.—A. L. S.

*Results of the United States Government Sugar Experiments.* Eng. and Mining J. 1890, 50, 6—7.

IN 1885 the United States Department of Agriculture, under direction of the chief chemist, Dr. H. W. Wiley, began a series of experiments in the manufacture of sugar from sorghum cane. The main idea was to adapt the diffusion process which had been so successfully applied to sugar beets in Europe to the working of cane.

In order to make these experiments on such a scale as to be of practical value, this work was undertaken in conjunction with the large sugar works at Fort Scott, Kan. The first machinery was either imported from Germany or built from European plans, but it was found that, owing to the fibrous nature of the cane, neither the cutting machinery nor the diffusion batteries would work successfully.

It was also found necessary, in order to compensate for the additional water added to the juice by the diffusion process, to provide evaporating appliances that would not only be more economical, but also of correspondingly greater capacity than what was hitherto used with the more concentrated mill juice from the rolls.

The results of these experiments proved very successful, and attracted a large number of people who were interested in the sugar industry. France, Germany, Austria, Algiers, and Chili sent representatives, and delegates from a number of Sugar Planters' Associations were present during the progress of these experiments.

It was singularly fortunate that these sugar works were built adjoining the extensive works of the Fort Scott Foundry and Machine Works Company, whose management had an extensive experience in the field of practical sugar making, and the improvements brought out by that enterprising company during the last few years may justly be said to be the beginning of a new epoch in the history of sugar production in this country.

A series of attempts had heretofore been made to introduce diffusion in Louisiana, but all failed, owing to the difficulty of reducing the cane to a sufficiently fine condition to effect a good extraction of the sugar.

The cutters built by the German manufacturers that worked well on beets were found to have but a fraction of the same capacity when applied to cane, and the knives were constantly clogging, owing to the tough fibre of the cane. Moreover, they had to be fed by hand, making the operation very laborious and expensive.

The cutting machinery built by the Fort Scott Foundry and Machine Works Company overcomes all these difficulties. All that has to be done is to place the cane on an endless carrier, and the fine cane chips are delivered into the cells of the diffusion battery without any further manual labour. Moreover, the capacity of these cutting machines is almost unlimited, a number having been built with a capacity of 500 tons of cane per day.

One of the most important features is the multiple safety-dead knife, which is so arranged that it will at once yield and let through any hard substance like iron without any injury to the cutter. Last year all other cutting devices were abandoned, and the above-described cutters are now used in every sugar factory in this country where diffusion has been adopted.

THE TWO OPPOSITE CELLS OF A DOUBLE LINE DIFFUSION BATTERY.

TRIPLE EFFECT EVAPORATING APPARATUS.

The diffusion batteries have also been greatly improved by these manufacturers, one of the most important of their improvements being the working of the heavy doors by the use of hydraulic cylinders, this work having previously been done by manual labour.

A more recent improvement, but of still greater importance, is their new heating arrangement, by which the heat in the battery can be kept up independent of the circulation, and by the aid of which the juice in the battery may be kept above the temperature where fermentation can take place, if for any reason the work should be suspended for a few hours.

In the field of evaporation the Fort Scott Foundry has also produced much higher results, and the apparatus it manufactures for this purpose is radically different from that which has been commonly in use, and has shown a degree of economy and efficiency not heretofore attained by any evaporating device.

In the so-called standard double or triple effect evaporators, the heating surface is similar to a vertical tubular boiler, the liquid to be evaporated being on the inside of the tubes. This necessitates a deep body of liquor being from four to eight feet deep; and the liquid being confined inside the tubes, the vapour meets with a great deal of resistance. Moreover, the lime which had been used for clarifying the juice produces a deposit on the inside of the heating tubes, where it adheres very firmly and causes much trouble and loss of heat and capacity.

In the apparatus manufactured by the Fort Scott Foundry and Machine Works Company this construction has been reversed. The heating tubes are horizontal. The evaporation takes place from the outside of the tubes, causing any deposit to be easily detached. The heating tubes are inserted in such a manner that they can easily be removed, all joints being made by a very effective packing device. The heating surface can also be readily cleaned on both sides, and thus the deposit caused by lubricating oils from exhaust steam can be removed, which otherwise soon reduces the efficiency of an apparatus.

Another very important feature in the construction is that the apparatus can at any time be enlarged to any desired capacity by simply adding more shelves, and no change in foundations or in the original plan is necessary.

In evaporating appliances that produce the evaporation by causing the liquid to be evaporated to pass through a series of tubes in the form of spray, or run down the inside or outside of the tubes in a thin film, great loss is occasioned by the small particles of juice becoming entangled with the escaping vapour and loss of sugar and discolouration takes place owing to parts of the heating surface being at times bare. The heating tubes we are describing being entirely submerged in the apparatus, these troubles are entirely overcome, while the great efficiency due to shallow evaporation is retained. The liquid to be evaporated is only four inches deep, and this depth of liquor is regulated automatically so as to be just deep enough to cover the tubes.

The heating surface is also divided into compartments, which gives the apparatus a large evaporating surface. This, together with the shallow evaporation, gives a very high efficiency, and the amount of water evaporated per square foot of heating surface is nearly four times greater than the best results obtained with the vertical tube apparatus. The flow of liquor through the apparatus is continuous, so that liquor flows in at one end of the apparatus and out at the other at any desired density.

The evaporating apparatus is made to work from a single to a quadruple effect, and has been adapted to the evaporation of all classes of liquors, more especially for the evaporation of cane or beet juice, glucose liquors, packing house tankage, and tan bark extracts. The firm has also modified the apparatus so as to make it perfectly adapted to the manufacture of salt, and the fuel necessary to produce the salt has been reduced 75 per cent. as compared with what is used by the open pan process, and the manual labour has been reduced almost in the same proportion.

The salt produced is also of very superior quality. Instead of flat scale-like crystals produced in the open pans, the crystals are regular and uniform, and of much greater

purity, and the most superior table and dairy salt is produced without any grinding, screening, or other subsequent operation.

The great merit of this evaporating apparatus is shown by the fact that three-fourths of all the contracts made in Louisiana this year for multiple effects have been awarded to the Fort Scott Foundry and Machine Works Company.

One triple effect which the company is now building for the Caffrey Central Sugar Refinery at Franklin, La., will be the largest evaporating apparatus in the United States. It will evaporate one million pounds of water per day, and is guaranteed to evaporate three pounds of water for every pound of steam delivered from the steam boilers into the apparatus.

By the use of an apparatus consisting of six effects, it is claimed to be possible to evaporate six pounds of water for each pound of steam introduced into the apparatus, this being rendered feasible by the very shallow evaporation and large evaporating surface, and it is said that this claim is fully sustained by the performance of their evaporators erected on several plantations last year.

*A Process or Method of Extracting Sugar from Sugar Cane or other Sugar-Yielding Substances, and Apparatus for the Purpose.* A. Chapman, Liverpool. From C. A. Mattley, St. Lucia, West Indies. Eng. Pat. 12,021, July 29, 1889. 8d.

THE sugar cane or other sugar-yielding substance is first thoroughly disintegrated by a crushing, shredding, grinding, or other mechanical process, and the saccharine juice is afterwards removed therefrom by displacement by means of water or other liquid. The latter operation is carried on preferably in a tall cylindrical vessel provided with a false bottom and also with a true bottom which opens with a hinge for facilitating the removal of the exhausted pulp. The pulp is filled into this vessel on to the false bottom and water is added at the top through a perforated plate until all the liquor is driven out through a cock at the bottom of the vessel.—A. J. K.

*Apparatus for Estimating the Quantity of Glucose or Grape Sugar in Fluids.* A. W. Gerrard, London. Eng. Pat. 18,856, November 25, 1889. 4d.

See under XVIII., page 774.

*Improvements in the Manufacture or Production of Raw or Refined Sugar, and Apparatus to be used therein.* A. Fairgrieve, Edinburgh. Eng. Pat. 1247, January 23, 1890. 8d.

In the production of dry sugar from the purified liquor of the refinery or manufactory the following process is adopted. Concentration is effected in a closed pan under vacuum as speedily and at as low a temperature as possible. Having reached the "proof" point without, however, allowing grain to form, and the pan being full up to the practical working limit, feeding is discontinued and the vacuum gradually lowered to zero in such a manner as will maintain the contents of the pan at "proof" point. The increasing temperature due to the falling vacuum should never be allowed so to thin the "liquor" as to cause it to froth. Neither should the liquor be allowed to become so thick as to force grain to separate out. The massecuite is now ready for the drying apparatus, which must be thoroughly heated before use. The massecuite is run into the pan, which is jacketed with steam at 15 lb. pressure, to the depth of about 6 in., and well stirred with arms which revolve at about 40 or 50 revolutions per minute. By this means the massecuite is rapidly and continuously turned over and over and exposed to the action of the heat

and air. It quickly changes from the viscous state in which it enters the pan into that of a dry free sugar in a very fine state of division, as fine as flour, and well suited to its economical use in consumption. Lumps formed in the drying are broken up by rollers attached to each alternate arm. Twenty or thirty minutes suffices for the mixing and drying operations. The sugar is now discharged into a set of sieves set vertically one above another and below the drying apparatus. Besides the usual back and forward action the sieves are so arranged as to slightly oscillate and "dump" after the manner of the self-acting machine for arranging wooden match sticks in the sets for heading. Advantages claimed for this process over the one usually adopted are extreme simplicity and economy, saving in cost of plant, space, fuel and hand labour. The resulting product is in the form of "flour," instead of being grainy as usual. The apparatus required is described by aid of drawings.—A. J. K.

*Improved Process for the Manufacture of Sugar.* C. Steffen, Vienna, Austria. Eng. Pat. 3589, March 6, 1890. 8d.

Is the evaporation of sugar in a vacuum pan liquor of good quality is first run in, which produces a crop of crystals and a syrup less pure than the original liquor. A liquor is now run in of the same purity-coefficient as the syrup in the pan, with the result that the crystals are enlarged and a still more impure syrup is formed as a mother-liquor. This is again fed by a liquor of same purity-coefficient as the mother-liquor, into which it is run, and the process is carried on until finally a very impure liquor is fed in. It is claimed that better results are obtained by this process than by feeding continuously with liquor of a uniform purity, and the process is applied both in the factory and in the refinery.—A. J. K.

*Improvements in the Method of and Apparatus for the Manufacture of Starch and the Treatment of the Residues obtained therein for Various Purposes.* S. Spitzer, New York, U.S.A. Eng. Pat. 4181, March 17, 1890. 8d.

The process consists of a method of preparation of starch by means of water only, without the use of any acids or other chemicals. The grain is first softened by steeping in water, and is then conveyed to a pair of crushing rollers geared so as to produce friction by their surfaces travelling at different velocities. From the crushing rollers the grain passes to a separating apparatus which consists of a vessel with a false lining, through the perforations of which the starch is forced by revolving beaters into an outer vessel. From the outer vessel the starch milk is conveyed into a series of sieves arranged vertically so that the starch flows through the coarser sieve into a finer one and so on, thereby removing any remaining husk, bran or other foreign matter. From the bottom sieve the starch liquor flows away into a settling tank, where the pure white starch separates out. It is afterwards dried and is ready for the market. The bran and husk being quite free from injurious chemicals, can be worked up into a good food for cattle, and the gummy matters separated and made into glue or paste. Drawings of the plant used are given.—A. J. K.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*Saké-Brewing in Japan.* M. Ikuta. Chem. Zeit. 14, 439.

SAKÉ is a very popular drink in Japan, it is prepared from rice by fermentation, the manufacture being carried on from September to February only, as in the summer the fermentation cannot be properly controlled. It is a pleasant light yellow liquid, smelling of alcohol, its specific gravity is about 0.99 and contains on an average 15 per cent. of alcohol.

The manufacture takes place in three stages.

1. *Preparation of Koji.*—The finest rice is boiled in an iron kettle with sufficient water to soften it; after cooling it is brought into the koji chamber, the outside walls of which are covered with earth and the interior with straw, by which means the temperature of the interior is kept up.

The rice is here mixed with a little moyaschi (a yeast obtained from a previous fermentation) and remains in the chamber for two days, by which time most of the starch of the rice is converted into dextrose and it is then called koji.

2. *Preparation of Motoh.*—Koji, fresh boiled rice, and water are mixed in a wooden vat in the proportion to form a thin paste. Wooden casks containing warm water are placed in this liquid every day; after one or two days a frothy fermentation takes place, which is allowed to continue 30—40 days, during which time the temperature rises to 37° C.; at the end of the period the liquid contains 10 per cent. of alcohol and is called motoh.

3. *The Third Stage.*—Freshly boiled rice, koji, and motoh are mixed with a little water. The mixture ferments a little, but without appreciable rise in temperature. As soon as the froth ceases to form on the surface, i.e., in 8—10 days, the process is finished.

The fermented fluid is filtered through cotton bags and put into casks and allowed to stand till clear. It is then heated in an iron vessel to 44° C. and is then run into casks.

The residue remaining in the cotton sacks has been used from time immemorial in Japan for the manufacture of vinegar.—A. L. S.

*Communication from Guayaquil. The Quality of the Spirit obtained from the Sugar Cane.* C. Monheim. Chem. Zeit. 14, 439.

By the use of modern plant it is quite possible to obtain a spirit of fair quality. In the interior of Ecuador the most primitive form of still is in use and the product is very impure. It is used in the manufacture of liqueur, cognac, &c. The liquors prepared from this impure alcohol have more terrible intoxicating effects than any other that the author is acquainted with, being much worse than the crude spirit from potatoes, grain, &c. This alcohol retains its noxious impurities with more tenacity than any other crude spirit and there seems to be no satisfactory way of purifying it.—A. L. S.

*Contributions to the Knowledge of the Composition of Wort and Beer.* H. Elien. Zeits. f. angew. Chem. 1890, 291—298, and 321—326.

1. *The Determination of the Solid Extract.*—A weighed quantity of the beer or wort of known specific gravity is introduced into a small stoppered glass weighing tube 40 mm. diameter and 35 mm. high. This is placed in an oven, the temperature of which is kept at about 97° C. by a steam jacket; the oven is hermetically closed and is connected with a water injector pump. By admitting a proper quantity of air through a second tube the pressure in the oven is maintained at about 250 mm. of mercury. The water quickly evaporates from the wort, and when most of it has been driven off the supply of air is

further diminished until the pressure within falls to 35—45 mm.; the small quantity of air which is still admitted is first dried by sulphuric acid. The residue in the tube froths up and soon dries. The tube is weighed at intervals until it ceases to lose weight after 4—5 hours further heating. This usually takes 10—15 hours. The author has satisfied himself, by making cupric reduction determination before and after drying, that the wort suffers practically no decomposition by this treatment.

The results obtained are considerably lower than those obtained by previous observers (Schulze and Ostermann, *Zeits. f. das ges. Brauw.* 1878, 248; 1883, 10; and Balling, *Die Bierbrauerei*, 3 Aufl. 1865, 128). This is due to the fact that these observers dried their extracts imperfectly, Schulze working with a stream of air at 70°—75°, at which temperature maltose does not lose its water of crystallisation. The author has made determinations with hopped and unhopped wort and beer residues, and finds that the same table will apply to all. The table given below is abbreviated from the one accompanying the paper:—

II. (A.) *The Determination of Maltose in Wort and Beer.*—The usual method for determining maltose in wort and beer is to determine the cupric-reducing power and to calculate this as all due to maltose. The author considers that other reducing bodies are present in these liquids and that consequently the method gives erroneous results. If some wort be sterilised and then fermented at 25° C. with a pure cultivation of *saccharomyces cerevisie* until the fermentation is completed, it is found that the solution still possesses a reducing power; the author has set himself to determine, (1) if the sugar which has fermented be all maltose and, (2) if the reducing power remaining after fermentation be due wholly or in part to maltose. A definite quantity of wort is fermented with a pure cultivation of *saccharomyces cerevisie* and the following factors are determined both before and after fermentation:—*Specific gravity*, which gives by the tables above, the total solids; *the reducing power*, determined gravimetrically, and *the same* after boiling with dilute hydrochloric acid which converts all maltose and dextrin into dextrose. Several experiments of this kind were made, of which the following may be considered a fair specimen.

Before Fermentation.	17 Days after.	Difference.
Sp. gr. .... 1.05630	1.02144	..
Extract ..... 13.46	5.21	8.25
Reduction .... 9.433	1.208	8.23
Dextrose ..... 13.098	4.514	8.58 = 8.15 maltose

All the experiments indicated that the sugar which had fermented was all maltose. Of these three processes for determining maltose, the author considers the fermentation one the best, the difference between the amount of extract before and after fermentation will always be greater than the amount of maltose fermented, as part of the maltose and other matter is used up in the growth of the yeast, which is filtered out. A correction therefore should be applied for this, which the author is engaged in determining.

The second method by determining the decrease in reducing power the author does not consider sharp enough.

The third method by estimating the amount of dextrose produced by boiling with hydrochloric acid both before and after fermentation is open to the same objection as the second, and also owing to the fact that other bodies besides maltose produce dextrose under these conditions, and the amount of dextrose produced from these bodies appears to increase after fermentation.

It is evident that in order that the first method may be adopted it must be shown that all the maltose is destroyed when the fermentation has stopped, *i.e.*, that the reducing power which the beer still possesses after complete fermentation is not due to maltose. This the author has done as follows: two portions of the same wort were fermented completely by a pure yeast; when the fermentation had stopped one of the liquids was analysed, but to the other a small quantity of pure maltose was added, when a brisk fermentation took place. After this second fermentation was finished the liquid was analysed and found to have the same composition as the first, thus showing that whatever remained in it was not free maltose.

In converting dextrin and maltose into dextrose, the author has found that the best proportions are 1.5 per cent. extract solution and one-twentieth volume of hydrochloric acid sp. gr. 1.19, heated in boiling water for three hours.

(n.) *The Value of the Maltose Determination in Practical Brewing.*—It may generally be considered that the amount of maltose in beer should not exceed certain limits, and so a knowledge of the amount of maltose remaining after fermentation is very useful, as if too large a quantity be present the beer cannot have been properly fermented, and therefore will not be stable.—A. L. S.

*On Cider and Perry.* P. Kulisch. Landw. Jahrb. 1890, 83.

CIDER and perry have many points of resemblance in their chemical composition. The common idea that the latter contains more sugar than the former is erroneous, the larger proportion of acid in cider masking the taste of the sugar. The total soluble matter is higher in perry than in cider, as a rule, and it also contains more tannin. The author discusses the question of distinguishing chemically between true wine made from grapes and that derived from other fruit. The characteristic difference appears to be the absence of tartaric acid free and combined in cider and perry; other differences exist and are useful in aiding judgment, but are not separately conclusive. For example, the percentage of alcohol in a fruit wine is lower than is met with in a genuine grape wine except in very poor years; further, the proportion of acid is not correspondingly high, while the rest of the soluble matter as well as the percentage of ash is higher than in a grape wine, and the ash itself is poorer in phosphoric acid. At the same time the total nitrogen in the fruit wine is lower than in the other. No safe deductions can be made in the case of doctored or fortified fruit wine, as the introduction of a little genuine wine renders useless the one certain test, *viz.*, the absence of tartaric acid.—B. B.

*Some Chemical Properties of an Alcoholic Extract of Brewers' Yeast.* J. de Rey-Pailhade. Bull. Soc. Chim. 1890, 3, 171—174.

AN alcoholic extract of brewers' yeast is prepared by mixing washed and pressed yeast with an equal volume of alcohol of 86 per cent.; the mixture is filtered, a clear yellow liquid, containing about 46 per cent. of alcohol,

being obtained. When 5 cc. of this extract are placed in a test tube along with 1 grm. of washed sulphur or 1 cc. of a saturated ethereal solution of sulphur, hydrogen sulphide is evolved, as is shown by the blackening of a strip of paper moistened with lead acetate. The name of *philothion* is given to the substance in the extract which possesses this curious property of causing the formation of hydrogen sulphide. One litre of the freshly prepared extract produces 10 mgrms. of hydrogen sulphide. After exposure to the air for two or three days the extract loses its property of generating hydrogen sulphide from sulphur, or, in other words, the philothion is destroyed. The addition of small quantities of hydrochloric or sulphuric acid renders philothion inactive; on neutralising the acid, the activity of the philothion is restored. When the extract is decolourised by animal charcoal the philothion is removed. Alkalis hasten the destructive action of oxygen (air) on philothion. Philothion is found in most animal tissues and in the young and active parts of plants; it probably plays an important physiological part in the living cell.—E. B.

*Wine from Dried Grapes and its Richness in Total Nitrogen.* P. Cazeneuve and L. Ducher. Bull. Soc. Chim. 1890, 3, 514—518.

THE problem of identifying wine made from dried grapes and distinguishing it from natural wine has never been solved. So recently as July 30th, 1889, the International Congress at Paris declared that there was no process for detecting with certainty the presence of wines from dried grapes, in natural wine. Various unsuccessful methods have been proposed, such as determinations of the levo-rotary or dextro-rotary power, the percentage of gum, or the variety of bacilli present.

The authors failed to confirm Giraud's supposition that a levo-rotary unfermentable principle was present in the wine of dried grapes; but, considering that as fruit matures its albuminoid matters increase, they believed that dried grapes would be found to be richer in nitrogen, which quality might also be persistent in the wine.

To determine if this were so, 5 cc. of wine were dried on a water-bath with plaster; 5 grms. of plaster sufficed for dry wines, but 10 grms. were required for sweet wines. The dried residue was ignited with copper oxide according to the method of Dumas.

The results were as follow:—

	Nitrogen in Grms. per Litre.
Dry white wines—	
Natural.....	0.275
From dried grapes (average of three samples) ...	0.248
Sweet white wines—	
Natural—1st sample.....	1.106
2nd sample.....	1.085
From dried grapes—1st sample.....	1.510
2nd sample.....	1.424
3rd sample.....	1.523
Red wines—	
Unclearified.....	0.340
Clarified.....	0.276

Thus, in the above samples of sweet wines, there is a marked increase of nitrogen in wine from dried grapes. The close agreement between the different samples is noteworthy. The authors account for the absence of difference between the dry wines by the explanation that the albuminous matters would be diminished by the longer fermentation and by clarification and filtration. The effect of clarification is shown in the above results with red wines.

—D. A. S.

*The Vacuum Method of Drying Barley and Malt, with a Direct Determination of the Extract in Beer and Worts.* C. N. Rieber. Zeits. f. d. ges. Brauw. 13, 97.

THE author makes use of a drying apparatus with paraffin bath. By means of a water-jet pump the pressure is kept down to 20 mm. of mercury. The substance to be dried is contained in a small thin glass tube, which during cooling

and weighing is closed by a well-fitting glass cap. If it be required to dry beer or worts in this manner, about 2 grms. of filter-paper, cut into strips, are introduced into the tube and about 5 cc. of the liquid dropped on top.

Barley at 110° C., under a pressure of 40 mm. of mercury, continues to give off water for about 30 hours; furthermore it seems that the barley after two hours' drying loses still 0.87 per cent. of its original weight, independent of the original moisture. For purposes of technical analysis, therefore, it is only necessary to heat for two hours under the above-mentioned conditions and to then add 0.87 per cent. to the result obtained.

Malt dried under the same conditions is slightly decomposed. The differences between two and 28½ hours' drying varied from 1.02 to 1.03 per cent. The author proposes to dry as above for two hours and take the result obtained, without correction, as this is identical with the result obtained by drying in an air-bath for 24 hours at 105°—110° C.

In determining the extract of worts and beers at 20 mm. pressure and a temperature of 70° C. constancy was attained after 66 hours' drying. The following results were obtained with beers and worts; they are here compared with the results given by Schultze's tables at 17½° C. and by Balling's tables at 15° C. :—

Schultze.	Balling.	Rieber.
Per Cent. 14° 10.	Per Cent. 13° 48.	Per Cent. 13° 38.
7.89	7.64	7.45
5.65	5.45	5.27

*Improvements in the Treatment or Preparation of Rice and other Grain or Cereals for Brewing and other purposes, and in Means or Apparatus employed therein.* A. Perry, London. Eng. Pat. 7909, May 11, 1889. 11d.

THE rice or grain to be treated is ground by any suitable means and washed in a chamber which is continually supplied with cold water. A screw conveyor at the bottom of this chamber transfers the grain as it subsides from the water to one end of the apparatus into a kind of well. From thence the now washed grain is elevated by another screw conveyor, and dropped into the hopper of the cooking apparatus. From this hopper the grain passes into a long tapering shaft, which is surrounded by a jacket into which high-pressure steam can be admitted. The grain is forced towards the narrower end of the shaft by means of a screw conveyor passing along its centre. The feeding end of the apparatus is provided with taps which convey steam and hot water to the material under treatment in order to soften and scald it. As the grain approaches the narrow end of the tube it is compressed, and is in consequence more readily gelatinised by the action of the heat. The cooked material issuing from the end of the apparatus is preferably converted into shreds or ribbons. This is best done by forcing it by means of pressing blades or rollers through a die or grating fixed at the bottom of a circular chamber. The shredded grain is dried by any suitable means. If desired, vegetable or fruit juices or colouring matters may be mixed with the grain in the cooking or shredding apparatus. Starch may also be added in the shredding apparatus. For designs and full description of the various apparatus above referred to, the original specification must be consulted.—H. T. P.

*Improved Apparatus for Cooling or Icing Beer or other Drinkables, also applicable for Warming or Mulling Liquids.* M. T. Neale, London. Eng. Pat. 10,506, June 28, 1889. 6d.

"The object of this invention is a cheap, simple, and expeditious means or apparatus for icing or cooling beer

or other drinkables" chiefly for use in public-houses or hotel bars. The liquid to be cooled flows through a tube or coil contained in a vessel filled with a freezing mixture, and the vessel is coated with felt on the outside. By replacing the freezing mixture by hot water liquids may be warmed or "mulled" in the same apparatus.—A. J. K.

*An Improved Method of Facilitating the Drying of Distillers' Spent Wash and similar Matter.* E. Larsen, London. Eng. Pat. 10,740, July 3, 1889. 4d.

THE invention consists in the addition of some light bulky substance, such as husks from oats, rice cones, malt combs, or brewers' grains, to the "wash," which is previously dried as much as possible by settling and pressing. The mixture thus formed is easily completely dried by means of any of the ordinary machines commonly used for drying grains, &c. The grains or cones added are then removed by sifting, and may be used again for a fresh portion of "spent wash."—H. T. P.

*Improvement in Apparatus for the Treatment of Yeast.* T. Vogel, Saalfeld, Germany. Eng. Pat. 10,764, July 3, 1889. 8d.

THE object of this apparatus is the aeration of yeast by forcing through it air in a finely-divided state. The special advantage claimed for the machine is that it can be easily cleaned as the separate parts can be readily dismounted for cleaning purposes. Full description is given with reference to drawings.—A. J. K.

*A Process for Purifying Alcohol, Wine, and other Alcoholic Liquids and Beverages.* P. C. Rousseau, M. J. de Chanterae, and M. J. D. A. de la Baume, Paris, France. Eng. Pat. 12,186, July 31, 1889. 4d.

ACCORDING to this invention alcoholic liquids are freed from impurities by treatment with a basic tartrate followed by a hyposulphite (thiosulphate). Tartrate of potash or soda, or preferably the double salt known as "Sel de Seignette" may be used. Among the hyposulphites those of barium and sodium have given excellent results. The alcoholic liquid contained in a suitable closed vessel is mixed with small quantities of the tartrate, being well agitated after each addition, until it reacts neutral or faintly alkaline to test paper. The impurities are now allowed to settle, which requires from a few hours to several days according to circumstances; but in any case the operation is considerably hastened by the application of heat, or by the action of light. Hyposulphite is now added in quantity equal to about one-third of the tartrate used. The liquid is well stirred and allowed to settle, when the clear portion may be drawn off and rectified in the usual way. This process is applicable to all kinds of alcoholic liquids, notably wines and rum, the flavour of which is greatly improved.

—H. T. P.

*Improvements in the Method of Producing Ferments.* L. Meyer, Stuttgart, Germany. Eng. Pat. 13,054, August 19, 1889. 6d.

THIS invention practically consists in impregnating some suitable material or "ferment-carrier" with a growth of the ferment it is desired to employ. Various animal and vegetable fibres and other substances may be used for this purpose; but, weight for weight, raw sheep's wool, freed from grease, is the most efficient. In carrying out the process any desired quantity of cleansed sheep's wool is dipped into a well-fermenting liquid, still containing about two-thirds of the sugar present at the commencement of the fermentation, fermenting wort, grape juice, or other liquid being taken according to the nature of the ferment required. After soaking, the wool is placed in a vessel which can be tightly closed, and kept at a temperature of 25—30° C. for a period of three days. The fermenting material is now

finished, and is employed by bringing it into contact with the liquid in which it is desired to produce fermentation. The improved fermenting material is very durable, and may be used over and over again. The process is applicable for all alcoholic fermentations. It may also be used for the manufacture of yeast, and for fermenting champagne made by the French method, a piece of the material being attached to the cork.—H. T. P.

*Improvements in Treating and Rectifying or Ageing Alcohol or Alcoholic Liquors or the like by Electricity.* A. de Méritens, Paris, France. Eng. Pat. 14,162, September 7, 1889. 4d.

This patent has reference to a method of increasing the electrical conductivity of alcoholic liquors. This is effected by dissolving in them sodium bisulphite. This salt has the advantage of liberating an equivalent of sulphurous acid, which, during the passage of the current, reduces the aldehydes and allied bodies present in the alcohol, so that by this process, in conjunction with treatment in the apparatus previously patented (this Journal, 1888, 860), alcohol free from aldehyde may be obtained. Further, this method when applied to worts, washes, &c., stops or retards secondary fermentation.—H. T. P.

*Improvement in the Process of Treating Cereals.* F. Dorr, Baltimore, U.S.A. Eng. Pat. 2450, February 14, 1890. 4d.

CEREALS, such as barley, wheat, rye, &c., in their fully matured condition, are first cleaned from the bran or husk in the usual manner, and are then subjected to the action of steam of from 150° to 250° F. When thoroughly cooked the cereals are partially dried and then passed through fast revolving burr-mills, dressed and ground, in contradistinction to being passed through rolls. The mills are heated by friction of the two faces of the stones, until the heat obtained is at least 200° F. before the grain is passed through. The product obtained is designated "Barlyne," and will keep in any climate.—A. J. K.

*Improvements relating to the Production of Malt.* C. Hof, London. From L. Röhmsam, Bamberg, Bavaria. Eng. Pat. 3579, March 6, 1890. 4d.

This invention deals with the manufacture of colour malt. The chief novelty consists in the conversion of the starch of the malt into sugar, previous to caramelisation. Charring of the grain is altogether avoided, and as a consequence beer brewed with this malt is altogether free from any burnt flavour. In practice "green malt" is placed in a revolving cylinder or "toaster," and moistened with 9—10 pints of warm water per cwt. of malt taken. The toaster is kept in constant rotation, the temperature inside it not being allowed to exceed 100° C. In about two hours the starch of the malt is converted into sugar. Thereupon the temperature is somewhat raised, and the rotation continued for about five hours more. By this means the sugar is more or less completely caramelised, although the husk of the malt hardly darkens at all. Finally, the malt is thrown out of the toaster, and heaped on a floor, preferably of stone, to cool. After removing the "comes" and cleansing, it is ready for use.—H. T. P.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

### (A).—CHEMISTRY OF FOOD.

#### PATENT.

*Improvements in Apparatus used in the Purification and Collection of Carbonic Acid Gas prior to its being used for Aerating (Soda) Water or other Liquors.* J. Childs, London. Eng. Pat. 11,565, July 19, 1889. 8d.

THE carbon dioxide gas, instead of being first washed and then collected in an ordinary gasholder, is passed through a chamber provided with shelves, upon which dry crystalline soda is placed. It is found that this removes the impurities in the gas, and any liquid which may be formed during their removal is run away by a pipe at the bottom of the purifier. The object of thus purifying the gas is to enable it to be collected and preserved in pliable bags (made up of two layers of canvas and three of rubber) instead of the ordinary holder. These would otherwise be rapidly destroyed by the action of the impure gas upon them. The specification is illustrated by drawings.—S. G. R.

### (C).—DISINFECTANTS.

#### PATENT.

*Manufacture of Bleaching and Disinfecting Liquor.* E. Hermite, E. J. Paterson, and C. F. Cooper, London. Eng. Pat. 8177, May 16, 1889. 4d.

See under VI., page 732.

## XIX.—PAPER, PASTEBOARD, Etc.

*Andanson Paper.* W. Herzberg. Mitt. k. Techn. Vers. Anstalt, Berlin, 1890, 82—89.

THE author has investigated sample lots of paper prepared from this well-known bast. They were of a pale yellow colour, but "dirty," i.e., flecked with spots, varying in colour from yellow to brown. These spots consisted of cellular residues, which, notwithstanding the thorough washing to which the fibre was subjected, it was found impossible to remove.

Subjoined are the results of the mechanical tests, (a) being a thin unsized paper, (b) a thicker paper, sized:—

	Tearing Length.		Mean.	Elongation at Fracture.		Mean.
	Along the Web.	Across the Web.		Along the Web.	Across the Web.	
(a)	Km. 6'49	Km. 3'69	4'79	Per Cent. 2'5	Per Cent. 4'1	3'3
(b)	6'31	3'72	5'02	1'0	6'2	5'1

The fibre possesses extraordinary fineness and capacity for forming a strong interlaced texture, which would render it capable of yielding paper as strong as and similar to the well-known Japanese paper.

A noteworthy characteristic of the fibre is its high percentage of mineral constituents. Subjoined are the results of complete analyses of the ash both from the original bast and the paper:—

#### ASH CONSTITUENTS OF ANDANSONIA DIGITATA.

	Raw Bast.	Paper.
	Aggregate Percentage 17.47, with 6.94 per Cent. CO <sub>2</sub>	Aggregate Percentage 5.35, with 1.72 per Cent. CO <sub>2</sub>
Lime .....	49.59	52.89
Magnesia .....	3.44	3.90
Alumina .....	0.11	0.18
Iron oxide .....	0.32	0.24
Potash .....	5.35	1.14
Soda .....	0.32	0.08
Silica .....	0.22	4.70
Phosphoric acid .....	0.54	2.97
Chlorine .....	1.03	1.23
Sulphuric acid .....	0.56	0.15
Carbonic acid .....	39.79	32.18
	99.61	9.86

It is interesting to compare with the above the subjoined results of analyses of cigarette papers prepared from hemp and flax fibre, A giving an aggregate of 0.35 per cent. and B, 0.44 per cent. of ash constituents.

	Raw Bast.	Paper.
	Aggregate Percentage 17.47, with 6.94 per Cent. CO <sub>2</sub>	Aggregate Percentage 5.35, with 1.72 per Cent. CO <sub>2</sub>
Lime .....	10.45	21.35
Magnesia .....	5.53	13.51
Alumina .....	5.05	9.66
Iron oxide .....	1.82	3.91
Potash .....	2.83	2.13
Soda .....	0.85	0.11
Silica .....	17.73	37.76
Phosphoric acid .....	10.85	5.61
Chlorine .....	1.31	0.79
Sulphuric acid .....	0.91	0.94
Carbonic acid .....	12.59	2.84
	99.95	98.91

The characteristic features of the Andansonia ash are the preponderance of lime and the low percentages of silica and phosphoric acid.

*Structural and Microscopic Characteristics.*—Fig. 1 shows the general disposition of the fibres in the bast

Fig. 2.

Fig. 1.

ANDANSONIA PAPER.

Fig. 3.

Fig. 4.

Fig. 5.

## ANDANSONIA PAPER.

complex. In Fig. 2—*a, b, c, d, e, f, g*—are reproduced the more important variations of the bast fibres, in point of microscopic structure. The cell walls and lumen show unusual irregularity; the ends of the entire fibres are mostly rounded, when fractured or drawn in the heating process there appears to be little tendency to resolve the cell wall into fibrillae. The length of the cells varies from 2.8 to 5.0 mm.; the average may be taken to be 4.2 mm. The brownish flecks in the paper before mentioned, when examined under the microscope, are seen to consist of groups of cells (Fig. 3), similar to the sclerenchymatous cells of straw. Occasionally also residues of vessels (Fig. 4) are to be seen. The structural changes observed during the progress of the solvent action of the ammonia cupric reagent are very characteristic. The successive stages are shown in Fig. 5, *a* to *c*. The result is obviously occasioned by the greater resistance of the outer portions of the cell wall to the action of the reagent. The particulars of the chemical treatment to which the fibre was subjected are not given.—C. F. C.

*Mineral Constituents (aggregate) of Paper-making Materials.* W. Herzberg. Mitt. k. Techn. Vers. Anstalt, Berlin, 1890, 89—92.

THIRTY-ONE samples of rags were investigated and found to contain on the average 3.06 per cent. of ash constituents. Twenty-two specimens of half-stuff, bleached and unbleached, prepared from rags, were found to contain on the average 0.74 per cent.

In unmanufactured fibrous raw materials the average lies between 1 and 2 per cent.; quantities in excess of 2 per cent., which may be taken as a maximum number, indicate the presence of adventitious mineral matters; in manufactured goods (rags, bagging, &c.) these may have been added in the form of mordants (dyed goods) or filling materials. It will be seen that they are for the most part removed in the process of boiling and washing.

Subjoined are the results of the author's determinations of "total ash" in commercial pulps:—

	Per Cent.
Sulphite pulp (1) .....	0.48
Sulphite pulp (2) .....	0.51
Sulphite pulp, bleached .....	0.42
Soda wood pulp, bleached .....	1.40
Soda wood pulp .....	1.34
Straw pulp .....	2.30
Straw pulp, bleached .....	1.22
Mechanical wood pulp (pine) .....	0.43
Mechanical wood pulp (fir) .....	0.70
Mechanical wood pulp (aspen) .....	0.44
Mechanical wood pulp (lime) .....	0.40

(Compare A. Frank on "Ash Constituents of Sulphite and other Pulps." Papier Zeitung, 1888, 893.)—C. F. C.

*Strength of Paper in relation to Thickness.* W. Herzberg. Mitt. k. Techn. Vers. Anstalt, Berlin, 1890, 92—94.

PAPERS were made containing 75 per cent. of linen, 10 per cent. of cotton, and 15 per cent. of wood cellulose, rosin sized; the weight of one (*a*) was 12 kilos. per 1,000 sheets,

of the other (*b*) 16 kilos. The mechanical tests gave the following results:—

—	Weight.	Tearing Length.		Elongation at Fracture.		Temperature and Moisture.
		Along Web.	Across Web.	Along Web.	Across Web.	
(a)	Grm. Sq. M. 87	Km. 4.85	Km. 3.48	Per Cent. 2.0	Per Cent. 3.4	15.8° C., 71 per cent.
(b)	117	4.58	3.23	2.2	4.4	17.5° C., 73 per cent.

Similar results were obtained with papers prepared from sulphite cellulose alone. Subjoined are the mean of the determinations: temperatures, 18.6°—18.8°; hygrometric state, 63—64 per cent.

—	Weight.	Tearing Length.	Elongation at Fracture.
(a)	Grm. Sq. M. 55	Km. 5.68	Per Cent. 2.1
(b)	90	5.40	3.0
(c)	170	5.17	3.7

With increase of thickness, therefore, there is a diminution of tenacity and an increase in elasticity.—C. F. C.

*Preparation of the New Russian Paper Money.* O. Hallsleben. Dingl. Polyt. J. 276, 181—183.

THE special feature which characterises the paper used for the preparation of the new Russian bank notes is that it contains an impression of a silk web, the meshes of which are of a definite form. This web is prepared upon a loom worked by a machine of special design, and is not removed from the rollers, but taken to the paper mills and worked into the paper during its manufacture, rollers of special construction being used, so that the original form of the silk meshes is retained.—D. B.

*Treatment of Ramie (Urtica Nivea).* J. Armandon. Monit. Scient. 1890, 401—402.

THE author has successfully cultivated the *U. Nivea* in his experimental garden at Saint-Maurice Canavere. The bast strips were treated with a solution of ordinary rosin in soda, containing 3—4 per cent. of the former. After boiling under slight pressure for some hours, the fibre was removed, boiled with dilute alkaline solution (2 per cent. Na<sub>2</sub>O), well washed with water, and bleached with hypochlorite. Thus prepared the fibre was brilliant white. The yield was 21 per 1,000 of the green stems. The fibre thus prepared appears to be easily dyed.—C. F. C.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Eucalyptus Oil.* Schimmel and Co. Zeits. Anal. Chem. **29**, 222—223.

EUCALYPTUS oil, now in the market, contains 50 per cent. of eucalyptol, together with phellandrene. To recognise the latter constituent it is advised to mix 1 cc. of the oil with 2 cc. of glacial acetic acid, and to then add 1—2 cc. of a strong aqueous solution of sodium nitrite. On gently agitating, the separated oil almost immediately solidifies to a crystalline mass of phellandrene nitrite.

The highest boiling portions of eucalyptus oil (portions boiling from 220°—260° C.), contain euminal. To identify the pure compound, obtained from the sodium bisulphite compound, oxidation was performed by means of permanganate; the acid thus obtained possessed the melting point of euminal acid.

Good oil should contain from 50—70 per cent. of eucalyptol; the best kinds are so rich in eucalyptol that they may be semi-frozen by a freezing mixture.—T. L. B.

*The Phenol of Sassafras Oil.* C. Pomeranz. Monatsh. **11**, 101—103.

THE etheral oil of the American cinnamon tree *Laurus sassafras* has been shown by Grimaux and Ruott to contain 10 per cent. of a terpene,  $C_{10}H_{16}$ , 90 per cent. of saffrol,  $C_{10}H_{16}O_2$  (this Journal, 1890, 100), and a small quantity of a body possessing the characteristics of a phenol—probably eugenol. This last can be isolated by shaking the oil with dilute alkali, separating the alkaline liquid and acidifying with sulphuric acid, when a brown oil separates, the greater portion of which, when dried, distils over at 246°—247° C. The author obtained 7 grms. of the oil from 3 kilos. of the sassafras oil, and showed both by analysis and by the preparation of the characteristic benzoyl derivative that the phenol in question is undoubtedly eugenol—

—C. A. K.

*Lobeline.* H. Paschke and A. Smita. Monatsh. **11**, 131—132.

To obtain the alkaloid from *Lobelia inflata* the leaves are extracted with warm water acidified with acetic acid, the extract concentrated, made alkaline and the alkaline solution extracted with ether. The acid extract is then treated with water, rendered alkaline and again extracted with ether; after distilling off the latter the alkaloid remains as a viscous honey-coloured oil, with a smell akin to that of honey and tobacco. For further purification the oil is dissolved in ether, extracted with water acidified with hydrochloric acid, the acid extract then rendered alkaline and the resulting solution again extracted with ether. After distilling off the ether, the residue is dried over caustic alkali and distilled in a current of hydrogen. When lobeline or its sulphate is suspended in a 10 per cent. caustic potash solution and a 4 per cent. solution of potassium permanganate is gradually added, the whole being gently warmed on the water-bath, benzoic acid results, which can be extracted by means of ether after filtering off the manganic hydrate and acidifying the resulting solution. The identity of the acid formed with benzoic acid was proved by analysis and by its characteristic properties, whence it appears that lobeline contains an aromatic nucleus.

Further investigations on lobeline are in progress.

—C. A. K.

*Notes on some Pharmaceutical Preparations.* A. Weller. Chem. Ind. **13**, 162—165.

THE following notes are based on the report for the year 1889 of the "Vereinigte Fabriken chem.-pharm. Produkte Feuerbach," Stuttgart and Frankfurt a. M., Zimmer and Co.

*Arecoline.*—Jahns (this Journal, 1889, 210) and Marmé (Pharm. Zeit. **34**, 12) have studied the liquid alkaloid contained in areca-nut and assign to it the formula  $C_8H_{13}NO_2$ . It has an action on the heart similar to muscarine, slows the respiratory action, and strongly affects the peristaltic contraction of the bowels. Applied in small amount to the eye, it powerfully contracts the pupil.

The other alkaloid, arecaine, contained in areca-nut, is physiologically inactive.

*Atropine.*—Keen commercial competition has greatly lowered the prices of atropine salts. Ladenburg and Hundt (Ber. **22**, 2590) isolated from quinine tropate by fractional crystallisation dextro- and levo-rotatory quinine tropates and from these salts have further separated a dextro- and a levo-rotatory base, of which the latter resembles hyoscyamine, but is by no means identical with it.

*Caffeine.*—English competition in this article has reduced its price to such a degree that its production in Germany is out of the question. Amongst newer salts of this alkaloid is the phenate, which is also administered by injection.

*Quinine.*—The exports of cinchona bark from Ceylon and British India during the last eight years have been as follow:—

Year.	From Ceylon.	From British East India.
1881—82	Lb. 3,669,895	Lb. 428,497
1882—83	6,925,598	611,618
1883—84	11,492,917	396,019
1884—85	11,678,360	715,730
1885—86	15,364,412	857,040
1886—87	11,438,260	1,286,900
1887—88	11,704,332	1,449,315
1888—89	10,798,663	3,071,098

The proposed formation of a syndicate of quinine planters is rendered impossible by the present system of working, under which most of the planters are supported by loans of money from England, which are repaid in produce so that the planters have not a free hand in the disposal of the latter. The Dutch Government is largely encouraging the planting of cinchonas in Java. The exports from this source have risen from 1,104,534 Dutch lb. in 1883—84 to 4,415,631 lb. in 1888—89.

The price of quinine fell in June 1889 to 11d. per oz., the lowest price it has yet reached. It rose again, however, towards the close of the year, being quoted in London at 1s. 3d. per oz. The sales of this alkaloid have been very large, considerable quantities being required during the epidemics of *dengue* fever and influenza. As a prophylactic against malarial infections, quinine is still unequalled. The quinine-testing question is decided in favour of Kerner-Weller's ammonia test (Archiv. Pharm. (25), **3**, 16—17). Skrap and his pupils have shown (Monatsh. **10**, 39, 51, 65, 220; this Journal, 1889, 474, 815, 960) that the cinchona alkaloids are chemically closely related.

Of new salts of quinine, the bromide is of value in the treatment of neuralgia; the glycyrrhizinate very effectually masks the bitter taste of the alkaloid; quinine-hydroquinone hydrochloride and sulphate are types of a new class of double compounds of quinine and phenols, which are more rapid febrifuges than the corresponding simple quinine salts (Hesse, Pharm. Zeit. **34**, 24).

The consumption of cinchonidine, cinchonine, and quinoidine decreased; on the other hand quiniidine was in such demand that its price bordered on that of quinine.

Oudemans has worked on *cupreïne* (Rec. des trav. chim. des Pays-Bas, 8, 147).

The importation of coca leaves greatly diminished in consequence of the preparation of crude *cocaine* in South America. The price of this alkaloid has kept very steady.

Howard published (Pharm. Journ. and Trans. 969, 569) some interesting analytical results. He finds that species of erythroxylon, other than erythroxylon coca, contain only 0.02 to 0.03 per cent. of the alkaloid.

Numerous analytical tests for this alkaloid have been published during the past year. The chromate test of Metzger (Pharm. Zeit. 34, 92), despite the objections of Giesel (*ibid.*, 93), is very serviceable.

Liebermann, Hesse, Einhorn, and others, have pursued investigations in regard to the constitution of cocaine and its derivatives and associates.

*Cytisine*, according to Radziwillowicz (Arch. d. Pharm. Instituts zu Dorpat, 2), Prévost, and Binet, is intermediate in its physiological action between strychnine and curarine.

*Hydrastine* has been further investigated by Freund (this Journal, 1889, 412, 637, 1006).

*Hydrastinine*, a product of the oxidation of hydrastine, is a powerful base, whose salts, injected hypodermically, act as haemostats (Falk, Ther. Mon. 4, 19).

*Hysocine*.—The haloïd salts of this dye are largely used as soothing agents in cases of mental disease, for which purpose Kny (Münch. med. Woch. Nos. 45 and 46), Klinker, Dornblüth, and Rabow consider it unrivalled.

*Lobeline*.—The active constituent of *Lobelia inflata* gives excellent results in cases of dyspnea and spasmodic asthma, and is much to be preferred to the old Galenic preparation, as it does not induce vomiting or diarrhoea (Nunex, Brit. Med. J. 1889, 1051).

*Mandragorine*, prepared by Ahrens (Ber. 22, 2159), is possibly isomeric with the belladonna alkaloids. It is mydriatic. As yet it has not been employed.

*Opium alkaloids*.—The price of opium, and consequently of morphine, had a general upward tendency.

Flückiger (Archiv. Pharm. 27, 721, 769), Dieterich, Petersen, and Holdermann have described methods of estimating the alkaloids in opium.

Bardet and Adrian found morphine in *Escholtzia Californica*, previously recommended by Ter Zacarant (Bull. gén. de Thérap. 1889, 21) as a harmless hypnotic.

*Codeine* increases in importance. Dornblüth (Ther. Mon. 3, 363) recommends it as a hypnotic in cases of mental disease. For hypodermic administration codeine phosphate is preferred.

*Narcotine meconate* has recently appeared in commerce.

Roserehen continued his researches on *narcotine* (Annalen, 254, 334, 359).

*Pelletierine*.—Bérenger-Férard (Bull. gén. de Thérap. 1889, Feb.) recommends this alkaloid as being the most powerful and certain vermifuge known.

*Physostigmine* remained almost without change. The consignments being small in amount, the price of the raw material, Calabar beans, slightly advanced. This was also the case with Jaborandi leaves, the material from which *pilocarpine* is prepared.

*Quebrachine* hydrochloride is recommended as a specific for asthma and dyspnea.

Pawinski (Gaz. Hebdom. de méd. de Varsovie, 1889, June) finds the administration of *Sparteïne sulphate* of service in many cases of functional cardiac or valvular derangement.

*Strychnine*.—Jaroschewsky states that this alkaloid neutralises the toxic and narcotic effects of alcohol, and is, therefore, to be regarded as a powerful antidote to alcoholism.

*Theobromine* and, more especially, the easily soluble theobromine sodium salicylate, also known as *diuretine*, act on the kidneys (von Schröder, Archiv. f. exper. Path. u. Pharm. 24, 85), without exerting any toxic action like the closely-related caffeine does. Gram reports favourably on the diuretic action of this alkaloid (Ther. Mon. 4, 10).

—E. B.

## PATENTS.

*A Process for obtaining Carbon Acids of Meta-amidophenol, and of its Alkyl Derivatives.* C. Kolbe, Dresden, Germany. Eng. Pat. 12,191, August 1, 1889. 6d.

META-AMIDO-PHENOL is heated under pressure in a closed vessel to about 110° C. with about four times its weight of ammonium carbonate or other alkaline carbonate and five times its weight of water for 12 hours. The use of the carbonates of the alkaline earths is also claimed. The resulting solution is concentrated, the impurities separated by the addition of a little hydrochloric acid, and then the hydrochloride of the carbon acid obtained by the addition of an excess of hydrochloric acid. This is purified by dissolving it in soda and reprecipitating with acid. (The sulphate is less soluble than the hydrochloride.) To separate the free acid, the purified hydrochloride is treated with caustic soda or with sodium acetate and the solution then extracted with ether. The free acid melts with evolution of carbon dioxide at 148°, it dissolves readily in water, alcohol, or ether, but with difficulty in benzene, toluene, or chloroform. The alkaline salts are readily soluble in water, the hydrochloride and sulphate difficultly soluble.

Dimethyl- and diethyl-meta-amido-phenol are first converted into alkaline phenates, and the dried phenate treated under pressure with dry carbon dioxide at 120°–140° C. The free acids are separated from the sodium salts formed by addition of acetic acid, and can be purified by recrystallisation from hot toluene.—C. A. K.

*Improvements in Refining Apparatus or Furnaces for Camphor or similar Substances.* H. H. Lake, London. From W. V. McKenzie, New Jersey, and H. Braker, New York, U.S.A. Eng. Pat. 5367, April 8, 1890. 6d.

The apparatus consists of a furnace, refining pan and cover. The furnace is rectangular and is made of two casings of metal, between which asbestos is packed; in the bed of the furnace suitable openings for heating by means of gas are provided. The refining pan, made of suitable metal, extends nearly to the bottom of the furnace; the side walls of the pan converge downwards so as to allow the heat from the gas burners to be distributed all round the pan. The pan cover, also made of metal, rests upon suitable flanges of the refining pan, and is held firm by screws and luting; in the centre of the cover is an opening, which can be closed by a sliding cover or valve.

In refining camphor, &c., the crude material is placed in the pan, the cover fixed in position, and the heating started; at the end of the operation the opening in the cover is loosened to allow any evolved gases to escape, the cover removed and the camphor scraped off.—C. A. K.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*Action of Fatty Substances on Gunpowder.* S. Bein. Zeits. f. angew. Chem. 1890, 217–222.

THE points considered are the detonating point, the rate of combustion, and the explosive force. The powders examined were treated with blubber, coal-tar, wood-tar, sweet oil, olein, linseed oil, and petroleum.

Of coarse grained powders those containing 1 to 15 per cent. of fatty matter seemed to the eye to burn in the normal manner; those containing 16–22 per cent. of fat burnt by no means normally, and those containing 23–25 per cent. could scarcely be burnt at all. After the samples had remained for a fortnight in stoppered bottles, it was found that even those containing 5–7 per cent. of fatty matter were harder to burn than before, and burnt slower.

The detonating points were next determined (this Journal, 1890, 211). Coarse-grained powders containing 1–2 per

cent. of fat had a detonating point approximately the same as the detonating point before treatment with oil, but when the grease rose to 3 per cent. the detonating point rose  $25^{\circ}$ — $26^{\circ}$ , and when to 1 per cent. the detonating point was raised as much as  $38^{\circ}$ .

The way in which gunpowder burns depends not only on its composition, but also on the character of the grain, fine-grained powder burning quicker than the coarser varieties. Fine powder containing 1—2 per cent. of fatty matter burns normally, whilst, with 3 per cent. and over, ignition is hard

to effect in normal manner. Fine-grained powder containing 3 per cent. of fatty matter ignited at a temperature  $16^{\circ}$  higher than the same powder free from fatty substance. A sample containing 4 per cent. was kept for six weeks, and at the end of this time its ignition point was  $362^{\circ}$ , that of the same powder free from fatty matter being  $305^{\circ}$ . The following table shows the detonating points of a powder after 10 weeks' contact with various oils. The average detonating point of the powder itself was  $355.5^{\circ}$ . It is here to be noted that a maximum distinctly exists, as shown in the table.

Percentage of Fat.	1.	2.	3.	4.	5.	6.	7.	8.	9.	10.	11.	12.	13.	15.
Character of fatty matter:—														
1 part of petroleum . . . . .	363	370	377.5	385	392.5	400.5	405	411	416	422	..	432	..	440.9
2 parts of sweet-oil . . . . .														
Coal tar . . . . .	360.5	365.5	366	366.5	366	366	366	366	366.7	367	366.7	369	369.5	369.7
Linseed oil . . . . .	380	387	386	383.5	381	..	361	..	..	360	..	..	..	..
Olein . . . . .	359	366	375	380	387	..	381	376	..	368	..	..	..	..
Sweet oil . . . . .	357.5	362	370.5	..	376	..	370.5	..	..	367	..	365	..	..
Wood tar . . . . . $\left\{ \begin{array}{l} 0.5\% \\ 347 \end{array} \right\}$	352.5	357	362	368	371	..	370	..	..	361.5	..	360	..	..
Blubber . . . . .	357	368	370	376	383.5	388	389	..	385	..	..	382	..	378.7

The rate of burning forms likewise an important feature in the character of a gunpowder. The interstices in the case of fine powder are very small, and hence the passage of the flame is considerably retarded. To investigate the rate of burning of greased samples, long cylindrical metal tubes, open at both ends, were used. These were filled with the powder and the time of burning was noted in seconds. It was shown that samples containing 2 per cent. of fatty matter required a longer time for burning than did the pure sample; with 4—5 per cent. of fatty matter double the time was required, and some samples containing still more fatty matter refused to burn completely. Similar results were obtained after allowing the samples to stand for three weeks. This may be explained by considering that the oil during combustion uses up a certain quantity of heat, which is abstracted from the heat of combustion of the powder. The powder is thus able to burn gradually only. Such action of fatty substances would, of course, enable the use of lighter gun-barrels on account of decreased expansive force of the gases, and would bring about the use of lighter weapons, and a consequent quicker movement of troops. It might be considered that a decrease in the expansive force of the gases in the barrel would bring about a decrease in the velocity of the shot. Against this the author advances the following:—At the moment of firing the velocity of the shot is 0; immediately after, a gas expansion takes place in the direction of the bore of the barrel, and the shot is driven towards the muzzle. If no new forces come into play the shot has now received the whole of its velocity imparted. If greased powder be used, however, this fires gradually, and fresh impulsive forces come into play. If  $p$  represent the acceleration of the shot, corresponding to the gas expansion at a particular point in the barrel,  $v$  the initial velocity, and  $V$  and  $V_1$  the velocity of the shot at two different points in the barrel, then—

$$p = \sqrt{\frac{n}{g}} [(V - V_1)^2 - (V - v)^2] \dots \dots (1),$$

when  $\frac{n}{g}$  is a constant determined for each weapon and shot.  $n$  is the sum of a coefficient depending on the density, elasticity, and other properties of the shot (determinable by experiment), and on the bore of the weapon. At first, when  $v = 0$ , we have:—

$$p_0 = \sqrt{\frac{n}{g}} (V_1^2 - 2 V V_1) \dots \dots \dots (2)$$

The maximum acceleration ( $p_m$ ) at a point  $m$  of the barrel is:—

$$p_m = \sqrt{\frac{n}{g}} (1 - V_1)^2 \dots \dots \dots (3)$$

$v$  being put =  $V$  in equation (1).

The difference of the squares of the greatest and smallest accelerations (equation 3)<sup>2</sup> - (equation 2)<sup>2</sup> is thus:—

$$p_m^2 - p_0^2 = \frac{n}{g} V^2 \dots \dots \dots (4)$$

If  $v = 0$  the velocity, at a point in the barrel, is from (2)

$$V = \frac{V_1^2 - \frac{n}{g} \cdot p_0^2}{2 V_1} \dots \dots \dots (5)$$

Then substituting in (4) we get:—

$$p_m^2 - p_0^2 = \frac{n}{g} \cdot \frac{(V_1^2 - \frac{n}{g} \cdot p_0^2)^2}{4 V_1^2}$$

and

$$V_1 = \sqrt{\frac{n}{g}} \cdot (p_m + \sqrt{p_m^2 - p_0^2})$$

$V_1$  is a maximum when  $p = 0$ , that is, the maximum velocity of a shot is attained when the gas evolution is gradual, and consequently the greasing of gunpowder has a very decided advantage and plays a very important part.

—T. L. B.

## PATENTS.

*Improvements in or relating to the Manufacture or Treatment of Explosives.* H. M. Chapman, Waltham Cross. Eng. Pat. 1115, January 21, 1889. (Second Edition.) 6d.

THIS is an invention for converting well-known explosives such as gun-cotton and other nitro-explosives into a gelatinised or horny mass, by treatment with suitable solvents and subsequent manipulation.

The patentee describes at great length, and illustrates by drawings, the special apparatus he uses for effecting the gelatinisation of the explosive, for removing the solvent, and, in certain cases, volatilising the agent which has been used for gelatinising the gun-cotton. He particularises the following four methods of gelatinising or agglomerating the explosive:—

“First; that in which the agglomerating agent, whether solid such as camphor, or liquid such as aldehyde or formic

ether, is evaporated or distilled or allowed to evaporate off completely. Second; that in which the agglomerating agents with boiling points too high to be safely volatilised off are left in the explosive, and partly or wholly fulfil the function of a 'moderator' or substance that reduces the rapidity of the explosion, such as acetate of amyl, the mono-di- and tri-acetins, oxalic ether, and the high-boiling point ketones and acetates. Third; that in which mixtures of the first and second, such, for example, as a solid, say camphor, and a liquid, say amyl acetate, are used together. Fourth; the employment of hydraulic or other pressure with or without the simultaneous application of heat in combination with any of the before-mentioned three methods, whereby the explosive under treatment can be gelatinised and rendered homogeneous with very much less of the agglomerating or gelatinising agent than would otherwise be required."

Nitro-starch can also be gelatinised by common ether or by any of the methods specified above. The use of "moderators" in nitro-explosives of the nitro-benzene and nitro-naphthalenes is one of the claims, and it is pointed out that although camphor has been used for hardening explosives, it has not been employed for gelatinising gun-cotton as described.—W. M.

*Manufacture of Explosives.* F. A. Abel, London, and J. Dewar, Cambridge. Eng. Pat. 8718, May 27, 1889. 4d.

THIS invention consists in the addition of about 10 per cent. of tannin to gun-cotton alone or mixed with nitroglycerin. Either the tannin is dissolved in such a solvent as acetone, and this solution is used for dissolving the gun-cotton, or the tannin is added to the solution of gun-cotton in acetone, and the solvent is eliminated in known ways. When tannin is added to gun-cotton alone the product is hard and can be granulated; when nitroglycerin is also used the product is gelatinous. The addition of tannin moderates the force of explosives such as gun-cotton and nitroglycerin, giving them a propulsive instead of a disruptive character.—W. M.

*Improvements in the Preparation of Explosive Compounds.* A. V. Newton, London. From A. Nobel, Paris, France. Eng. Pat. 9361, June 5, 1889. 6d.

THIS invention relates to the preparation of a similar explosive to that described in Eng. Pat. 1471, 1888 (this Journal, 1889, 214), without the addition of camphor.

The nitrocellulose is mixed with an equal weight of nitroglycerin until the latter is completely absorbed. This operation is conducted at the lowest convenient temperature (say 5° to 10° C.). It is advantageous to employ the nitrocellulose in the wet and pulped state, as the presence of water retards the dissolving action of the nitroglycerin and otherwise facilitates the intimate mixture of nitroglycerin and nitrocellulose. The mixing is continued until only water escapes on squeezing the material. The mass is next immersed in hot water of 80° C., and heated at that temperature for about one hour, until it has become gelatinised, so that nitroglycerin does not exude on pressure. The material is then rolled into plates or sheets as described in the specification referred to above.

The moist or dry nitrocellulose may also be allowed to absorb as much nitroglycerin as it can at, say, a temperature between 5° and 10° C., and the excess of nitroglycerin is removed by pressure. The mass is then gelatinised as before. Should nitrocellulose be used which is not quite insoluble in nitroglycerin under the above conditions, then the addition of about 20 per cent. of benzene to the nitroglycerin will prevent it from dissolving the nitrocellulose at this temperature. Another method consists in mixing nitrocellulose with two or three times its weight of nitroglycerin and gelatinising the mass as before and rolling it into sheets. The excess of nitroglycerin is removed by steeping the sheets in a solution of methyl alcohol to which 25 per cent. of water has been added, until sufficient nitroglycerin has been dissolved out. The material is then again rolled into sheets, &c. The chief advantage of this process is that the gelatinisation takes

place more quickly and at a lower temperature (50°—60° C.). The inventor, however, generally prefers the first described method of working.

The nitroglycerin can be easily recovered from the methylic alcohol solution, since, when the temperature of the solution is lowered to 5° C. the nitroglycerin separates out.—W. M.

*Improvements in Explosive Compounds.* W. B. McGavin, Woodford Green. From E. W. McGavin, Sydney, N.S.W. Eng. Pat. 9433, June 7, 1889. 6d.

ACCORDING to this invention an improved explosive compound is prepared by saturating sawdust with a solution of potassium picrate, drying the impregnated sawdust, and then mixing it with potassium and sodium nitrates and sulphur.—W. M.

*Improvements in the Manufacture of Dynamite.* C. O. Lundholm, Ardeer. Eng. Pat. 10,312, June 25, 1889. 4d.

THE inventor renders so-called black dynamite (this Journal, 1889, 818) flameless by kneading it with water, when a large proportion of water can be absorbed without causing exudation of the nitroglycerin, or nitrate of ammonia in the form of dry powder or strong solution is mixed with the dynamite.—W. M.

*Improvements in the Manufacture of Explosives.* C. O. Lundholm and J. Sayers, Stevenston. Eng. Pat. 10,376, June 26, 1889. 4d.

THE principal object of this invention is a means of combining large proportions of cellulose nitro-derivatives with nitroglycerin.

The inventors avail themselves of the fact that the cellulose nitro-derivatives have the property of taking up or absorbing the nitroglycerin when suspended in water.

According to one method of working the cellulose nitro-derivative in a fine state of division is made into a pulp with water, the nitroglycerin is made into an emulsion with water and this is poured into the pulp and the whole is vigorously agitated. All the nitroglycerin is uniformly absorbed by the cellulose nitro-derivative; the water can then be separated by straining and pressure, and the compound afterwards malaxated between heated rollers and made into suitable forms.—W. M.

*An Improved Machine for Compressing Gunpowder for Use in Cartridges.* J. Robb, Loanhead. Eng. Pat. 10,917, July 6, 1889. 8d.

"THE object of this invention is, by lateral and vertical pressure, to make the gunpowder of sufficient density and cohesion to be suitable for use in cartridges for small-bore or other arms and in accordance with the Government requirements." Drawings accompany the specification, which must be consulted for a description of the machinery employed by the patentee.—W. M.

*Improvements in Matches or Lighters of certain Form for Cigars, Pipes, and the like.* A. F. Hawksley, Altrincham. Eng. Pat. 11,320, July 15, 1889. 6d.

THIS invention relates to improvements on the previous patent No. 11,135, 1886, and consists essentially "in forming the match or lighter with a washer or filling of non-combustible material, such as asbestos, pipeclay, or the like between each mass of combustible composition" so as to prevent more than one mass of the composition becoming ignited at a time. The match thus consists of a series of alternating portions of combustible and non-combustible compositions formed into a rod which is kept in a suitable tube-like case.—W. M.

*Improvements in the Manufacture of Explosives.* F. A. Abel, London, and J. Dewar, Cambridge. Eng. Pat. 11,664, July 22, 1889. 4d.

THIS invention consists in making a gelatinous explosive by admixture of nitroglycerin with the highest nitrated cellulose or gun-cotton, instead of the soluble varieties hitherto used, effected with the aid of a solvent such as acetone.

Various substances may be added with the object of moderating the force of explosion.

It is stated that owing to the uniformity of the composition of the gun-cotton used, the manufactured product is also constant in composition and uniformly reliable in its action.

—W. M.

*Improvements in or relating to Explosive Cartridges.* J. C. Butterfield and T. C. Batchelor, London. Eng. Pat. 12,249, August 1, 1889. 6d.

THE object of this invention is to prevent explosive compounds containing a hygroscopic salt like ammonium nitrate from deteriorating by absorption of moisture. For this purpose the inventors, after carefully preparing the explosive so as to ensure its perfect dryness, fill it into a metallic case consisting of a hollow cylinder made of thin sheet metal, such as lead or other metal or alloys having the requisite ductility and toughness, the cylinder is closed at one end and has at the other a screw thread run upon the metal. A small metal cap, which has been dipped into some quick-drying waterproof paint, is slipped on to the screwed end, the paint inserts itself in the screw threads, and the excess exudes and forms a waterproof ring round the juncture of the cap and the cylinder.

When it is desired to fire the material, a hole can easily be cut in the end of the case and a detonator inserted. Two or more cartridges can be fired by one detonator by simply removing the caps and placing the cartridges together end to end.—W. M.

*An Improved Gunpowder Mixing Machine.* F. W. Barker, London. From P. A. Oliver, Pennsylvania, U.S.A. Eng. Pat. 18,916, November 25, 1889. 8d.

THIS invention consists principally in "the combination with a rapidly revolving tub balanced upon a central pivot of two agitators revolving rapidly in a contrary direction to the tub, and arranged upon opposite sides of its central axis." The tub is lined with wood, and a fine spray of water from a suitable pipe keeps the materials to be mixed moist, and thus ignition by friction is prevented.

The tub is driven at from 300—400 revolutions, and the agitators at 1,000 revolutions per minute. The object of the high speed is to throw the materials against each other with such violence that they are reduced to an impalpable powder and also thoroughly mixed. By opening an outlet door while the machine is still in motion the contents are discharged by centrifugal force.

Drawings accompany the specification.—W. M.

*Manufacture of Grained Smokeless Explosive.* W. Schückher, Vienna, Austria. Eng. Pat. 4243, March 18, 1890. 4d.

THIS explosive consists of a mixture of from 90 to 95 per cent. of explosive starch (xyloidine), and 10 to 5 per cent. of nitrobenzene. The ordinary machinery used in making gunpowder is employed. After long continued grinding in a ball-grinding mill, the mixture is in the form of an almost dry powder, it is then pressed into cakes, which are afterwards broken into grains, and the grains are coated with plumbago in the usual way.—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

*Sampling of Chimney Gases.* O. Schmidt. Zeits. Anal. Chem. 29, 136—138.

THE accompanying illustration shows an apparatus for taking samples of chimney gases and the like:—

APPARATUS FOR SAMPLING CHIMNEY GASES.

*a* is an acid carboy, filled with water, and fitted with a doubly-bored rubber stopper, *b'* is a syphon, which may be closed by a pinch-cock at *b''*. *c* is a glass cylinder fitted with a rubber stopper at each end; one end is connected, through the cylinder *i* containing glass-wool, with the chimney. The T-tube *d* is connected with *c* by means of rubber tubing *m*, and on the other side with a tube which passes to the carboy and which is provided with a tap *g*. In using the apparatus, the pinch-cock *b''* is released, *g* is opened and *e* closed; suction at *n* sets the syphon working. The gases enter at *h*, are deprived of solid matter by the glass-wool in *i*, and pass through *l* and *c* into the carboy. When it is considered that all air has been displaced from *i*, *c*, and *d*, *g* is closed and *e* is opened. To *d* is connected, by means of a capillary tube, a Hempel's burette filled with water. The levelling portion of the Hempel is raised until the water reaches *x*, after which the gases to be examined may be drawn directly into the burette by lowering the levelling tube.—T. L. B.

*An Apparatus for retaining at a Constant Strength Salt Solutions, &c.* O. Foerster. Chem. Zeit. 14, 607—608.

THE vessel *A* in which the solution is heated, is connected by the tube *a* with the apparatus *B*. Through the tube *b* the water falls in drops into *B*, and the superfluous water

RETAINING SALT SOLUTIONS OF CONSTANT STRENGTH.

flows off at C. The lower end of *a* is bent upwards to prevent the liquid in A, when boiling, from rising in the tube *a*. In the same proportion as the liquid evaporates from A, the water is supplied from B through *a*.—H. S.

*An Impurity in Barium Chloride.* L. Blum. Zeits. Anal. Chem. 29, 139–140.

A sample of barium chloride was bought as “chemically pure.” Permanganate solution was, however, reduced by it. The author considers that the salt was probably obtained as by-product in the manufacture of hydrogen peroxide, and would therefore be liable to contain small quantities of enclosed hydrogen peroxide.—T. L. B.

*Detection of Nitrous Acid.* Curtmann. Pharm. Centralhalle, 29, 600.

THE green colouration obtained with antipyrine in presence of free nitrous acid is recommended.—T. L. B.

*Characteristics of the Alkaline Earths and of Zinc Oxide.* G. Brügelmann. Zeits. Anal. Chem. 29, 126–129.

WHEN these oxides are prepared from the nitrates by simple ignition, the following results are obtained. Calcium oxide, strontium oxide, and barium oxide are got in regular cubes, zinc oxide in hexagonal pyramids, often symmetric twin crystals, and magnesium oxide crystalline, not amorphous as hitherto considered. The specific gravities compared with water = 1 at 15° C., are CaO 3·25, SrO 4·75, BaO 5·72, ZnO 5·78, MgO 3·38.

Igniting the carbonates in a covered platinum crucible yielded:—CaO (3·26), MgO (3·48), ZnO (5·42), all amorphous; SrO 4·45, not amorphous as hitherto considered, but crystalline.

By heating the hydrates in a covered platinum crucible were obtained:—CaO (3·25), MgO (3·41), and ZnO (5·52) all amorphous, and here again, contrary to what is usually stated, SrO (4·57) crystalline. Barium oxide appears to form in graphite or earthenware vessels hexagonal needles (5·32), in platinum crucible it is regular (5·74). Barium oxide is thus dimorphous. Furthermore the strontium oxide obtained from both carbonate and hydrate was perfectly white; the barium oxide obtained from barium hydrate (the carbonate is too difficult to decompose by heating), was also perfectly white, hence it may be assumed that these oxides when pure are not grey but perfectly white as calcium oxide is. It was also shown that anhydrous barium oxide does not take up carbon dioxide within the limits of decomposition of the hydrate and carbonate. The specific gravity of strontium oxide stands almost midway between the specific gravities of the oxides of calcium and barium.

It is to be remarked that the crystalline oxides here obtained crystallised directly from the fused mass, and were not first obtained in the amorphous condition and subsequently transformed into the crystalline by continued heating.—T. L. B.

*Occurrence of Arsenic in Zinc Oxide.* W. Stromeyer. Archiv. d. Pharmacie, 27, 549.

A SAMPLE of zinc oxide bought as pure was shown to contain arsenic by dissolving in hydrochloric acid and adding a sulphuretted hydrogen solution. The percentage proved to be 0·088.—T. L. B.

*The Molecular Refractive Powers of Salts in Solution.* E. Doumer. Bull. Soc. Chim. 1890, 3, 200–206.

THE author has determined the refractive powers of 90 salts by means of Trannin's “identimètre” or differential refractometer. The results obtained with 78 salts are tabulated, and serve to furnish generalisations. Seven salts gave anomalous results, which may be due to the possible

presence of impurities in them, most of them being difficult to purify. From the results the following conclusions are drawn:—

1. All salts which contain the same acid have the same molecular refractive power, provided they be constituted on the same chemical type. Thus the molecular refractive power,  $\mu P_m$  ( $\mu$  = refractive power of the dissolved salt compared with water,  $P_m$  = molecular weight of the salt) of chlorides of the type  $M'Cl$  is approximately 21·5; that of chlorides of the type  $M'Cl_2$  is 42·8, and that of sulphates  $M'_2SO_4$  is 42·5. It may be stated, as a corollary to this law, that the various basicities of a polybasic acid may be satisfied with different metals without effecting the molecular refractive power, thus the salts  $K_2CO_3$  and  $KNaCO_3$  have the same molecular refractive power.

2. The molecular refractive powers of salts of different chemical types are approximately multiples of one number. Thus for the following salts,  $KCl$ ,  $K_2SO_4$ ,  $Na_3PO_4$ ,  $PtCl_4$ ,  $Al_2(SO_4)_3$ ,  $Fe_2K_2(C_2O_4)_4$ , the values of  $\mu P_m$  are respectively 20·7, 43·1, 64·3, 89·8, 130·5, and 170·7.

3. The molecular refractive powers of salts are functions of the valencies of the metals in combination.

In the last example the valencies of the metals are respectively 1, 2, 3, 4, 6, and 8, and the refractive powers are approximately  $1 \times 21·5$ ,  $2 \times 21·5$ , &c.

4. The molecular refractive power of a double salt is equal to the sum of the molecular refractive powers of the individual salts of which it is composed.

The molecular refractive power of the double salt,  $AuCl_3 \cdot NaCl$ , is 80, which is very nearly the sum of the respective molecular refractive powers of  $AuCl_3 = 57·6$  and  $NaCl = 23$ .—E. B.

*Analysis of Sodium Aluminate.* G. Lunge. Zeits. f. angew. Chem. 1890, 227.

THE value of sodium aluminate used, e.g., in soap manufacture, is generally ascertained by determining the alumina as well as the sodium protoxide by gravimetric analysis, whereby the determination of the insoluble residue and of silica (silicate being present) is also necessary. If silica is, however, present in but small quantities the following method can be applied quickly and easily for technical purposes. Weigh a quantity of sodium aluminate, dissolve in water to a specified volume (the insoluble residue may be ascertained if required), withdraw with the pipette measured portions, add phenolphthalein, and afterwards standard hydrochloric acid solution. The reduction is complete when the colouration has disappeared. The amount of  $Na_2O$  is hereby determined. To the same liquid a drop of methyl-orange solution is added and the titration continued until the yellow colour of the liquid has changed to a permanent red. This change of colour takes place rather slowly; a preliminary test is therefore recommended whereby the acid is added a cubic centimetre at a time. Having thus approximately ascertained the quantity of acid required, in the actual test almost sufficient hydrochloric acid is added at once, and then the reaction finished drop by drop. When the red colouration remains constant for five minutes the reaction is complete. The amount of  $Al_2O_3$  is hereby ascertained, the indicator only assuming a permanent red colouration after all alumina has been converted into aluminium chloride, and a little acid in excess remaining. *Key* made a comparative test of both methods (gravimetric and volumetric analysis) with the following results:—

	$Na_2O$ .	$Al_2O_3$ .
	Per Cent.	Per Cent.
Gravimetric analysis.....	26·42	25·92
Volumetric analysis.....	26·42	26·03

This shows that the volumetric method is sufficiently exact; but it must not be forgotten that this is only the case in presence of small quantities of silica; where a larger amount of silica is present the gravimetric method must be applied.—H. S.

*On the Volumetric Determination of Alumina in Sodium Aluminate and other Similar Compounds.* G. Lange. *Zeits. f. angew. Chem.* 1890, 293—300.

K. J. BAYER (*Zeits. Anal. Chem.* 24, 512; this *Journal*, 1886, 11) described this process, according to which normal soda solution is added to the aluminium solution until the precipitate which is first formed is redissolved and two portions of this solution titrated with sulphuric acid, one with litmus as an indicator until a red colouration is produced, and the other with "Tropäolin" until the citron-yellow colour changes to orange-yellow. The difference between the amounts of sulphuric acid required to produce these changes is such that three molecules of  $\text{H}_2\text{SO}_4$  are equivalent to one molecule  $\text{Al}_2\text{O}_3$ . R. J. Thomson, using methyl-orange as indicator, obtained the same result. Cross and Bevan (this *Journal*, 1889, 233) on the contrary find the difference in the amount of sulphuric acid is such that 5  $\text{SO}_3$  are equivalent to 2  $\text{Al}_2\text{O}_3$ .

The author has made experiments using phenolphthaleïn as the first indicator and methyl-orange as the second, and comes to the conclusion that Cross and Bevan are wrong, and that three molecules of  $\text{H}_2\text{SO}_4$  are equivalent to one molecule of  $\text{Al}_2\text{O}_3$ . His determinations agree very well with results obtained by a gravimetric process.

He considers that Cross and Bevan, in titrating with the methyl-orange indicator, did not wait long enough to see if the colour was really permanent. He finds that working at ordinary temperatures it is necessary to wait at least 10—15 minutes, but by working with the solution at blood heat the indication is perfectly sharp.—A. L. S.

*Tannin Matters as Anti-incrustators for Steam Boilers.* L. Vignon. *Bull. Soc. Chim.* 1890, 3, 410—413.

THE author, having occasion to examine a number of mixtures sold as boiler disinfectants, remarked the presence in many of them of tannin matters, along with sodium carbonate, &c. One such mixture, in particular, was composed of 260 cc. of sumac extract at 30° B., and 106 grms. of anhydrous sodium carbonate, per litre. With a view to ascertain whether the tannin matter was of use or otherwise, a series of experiments was instituted. Five pieces of clean boiler plate of the same size were weighed, and, one being kept for comparison, the others were boiled for eight hours separately in the following solutions:—

No. 1.—Water of the river Rhône .....	1,500 cc.
No. 2.—Sumac extract of 30° B. ....	35 cc.
Water, to make .....	1,500 cc.
No. 3.—Sodium carbonate .....	15 grms.
Water, to make .....	1,500 cc.
No. 4.—Sumac extract .....	35 cc.
Sodium carbonate .....	15 grms.
Water, to make .....	1,500 cc.

At the end of the time mentioned the samples were removed, rinsed, brushed, cleaned with fine sand, dried, and weighed. The effects of the various solutions are shown in the following table:—

Solution.	Weight of Iron-plate before Experiment, in Grms.	Weight after Experiment, in Grms.	Loss, in Grms.
No. 1	100.420	100.370	0.050
No. 2	94.450	93.507	0.943
No. 3	98.250	98.245	0.005
No. 4	103.450	103.070	0.380
Sample kept	98.600	98.590	0.010

With the Rhône water the iron was slightly rusted; a deposit of calcium carbonate, mixed with some ferric oxide, was left in the bath. Sumac extract, used alone, caused the iron to become covered with a black coating of iron tannate; the bath was deeply coloured. No trace of rust appeared on the iron when sodium carbonate alone was

used; in the bath there was a slight deposit of calcium carbonate of a pure white colour. With the mixture of sumac extract and sodium carbonate the iron was covered with a black film and the solution was much discoloured. It appears, therefore, that (1), free tannin matters attack boiler-iron; (2), excess of sodium carbonate does not prevent this objectionable action; (3), sodium carbonate has no injurious action on boiler-plates.—E. B.

*Experiments on the Solubility of Minerals.* C. Dölter. *Monatsh.* 11, 119—150.

THE author has studied the action of distilled water on a number of minerals which are generally regarded as insoluble by heating them in sealed tubes to 80° C. for a number of weeks. Pyrites, Galena, zinc blende, stibnite, orpiment, bournonite, and copper pyrites, as well as rutile and cassiterite are more or less attacked, as much as 8 per cent. of the mineral being dissolved. Hematite and silicates such as heulandite, natrolite, anorthite and clabbsite are less readily acted on than the sulphides. Analysis shows that the minerals are dissolved as such, the dissolved portions having the composition of the original mineral. The quantity of water employed in the experiments is of necessity limited; the water was found to dissolve as much as 0.3 per cent. of its weight of substance. The addition of sodium fluoride to the water increases the solubility of rutile, cassiterite and hematite; sodium chloride has little effect. Carbon dioxide (not pumped in under pressure) increases the solubility of oxides and of silicates, but decomposition takes place during solution. Sodium sulphide or sulphuretted hydrogen considerably increases the solubility of sulphides, and stibnite is completely dissolved. Interesting cases of the reformation of crystals of the various minerals were observed in these experiments.

Gold heated to 200° C. in a closed tube with water containing 5 per cent. of sodium carbonate or silicate is dissolved in appreciable quantities to the extent of 1.5 per cent. of the weight of gold taken.—C. A. K.

*New Method of Estimating the Ferrocyanide in the Yellow Prussiate Melt.* R. Zaleski. *Zeits. f. angew. Chem.* 1890, 210—214.

TO the solution of the melt freshly precipitated zinc carbonate is added in excess; carbon dioxide is then passed through the liquid. After some time the clear solution is tested with potassium ferri-cyanide; the reaction is generally shown to be complete after about half an hour. The whole is then boiled for 10 minutes in order to decompose any dissolved zinc bicarbonate. After cooling and filtering an aliquot portion is titrated with sulphuric acid. The reaction taking place is represented by the equation:—

Sodium ferrocyanide is decomposed in an exactly analogous manner.—T. L. B.

*Determination of Ferrocyanides in the Residue from Gas Purifiers.* R. Zaleski. *Zeits. f. angew. Chem.* 1890, 301—302.

THE author has previously (*Zeit. f. angew. Chem.* 1890, 210, see preceding abstract) described a method for estimating ferrocyanides in crude potassium ferrocyanide, and he applies the same to the estimation of ferrocyanides in gas purifier residue.

Twenty grms. of the material are finely powdered, digested with 20 cc. of 10 per cent. potash solution, and the solution made up to 100 cc.; 45 cc. of the clear solution (containing half of the substance taken) is boiled in a 100 cc. flask until all ammonia is expelled, and then just neutralised with dilute acid. To this solution, which contains all the ferrocyanide as potassium ferrocyanide, 20 cc. of normal alkaline carbonate is added, and 5 grms. of moist zinc carbonate and a current of carbon dioxide passed through the hot solution for about half an hour. The solution is cooled, made up to

the 100 cc. mark, and 50 cc. of this titrated with decinormal acid, with methyl-orange as an indicator.

The 10 cc. of normal alkaline carbonate which has been added requires an equivalent quantity of acid, and if the acid be of such a strength that 1 cc. is equivalent to 0.001  $K_2CO_3$ , then the number of cc. of the excess of acid required multiplied by 0.23 and doubled gives the percentage of  $K_2FeC_4 \cdot 3H_2O$  in the material taken (this Journal, 1889, 732, and 1890, 111).—A. L. S.

*Quantitative Separation of Arsenic and Antimony.* O. Kochler. *Archiv. d. Pharmacie*, **227**, 106.

In his "Handbuch der Analytischen Chemie" (Sixth Edition, 2, 423), Rose mentions a method of separating arsenic and antimony by precipitating both with sulphuretted hydrogen and then gently warming with concentrated hydrochloric acid. The antimony trisulphide is alone dissolved. Some of the arsenic trisulphide is, however, apt to be dissolved as well. According to the present communication good quantitative results can be obtained by careful attention to concentration, and consequent prevention of the precipitation of the antimony. Small quantities of arsenic were taken in presence of large quantities of antimony. The antimony trichloride solution used had a specific gravity of 1.33, the concentrated hydrochloric acid was of sp. gr. 1.124 and the solution of arsenious acid contained 1 gm. of arsenious acid per litre.

It was found that to one part of the antimony solution at least two parts of the concentrated hydrochloric acid were necessary to prevent precipitation of the antimony by sulphuretted hydrogen from a hot solution.

For the separation 20 cc. of the antimony trichloride solution were mixed with 45 cc. of concentrated hydrochloric acid and 5 cc. of the arsenious acid solution; into the hot solution sulphuretted hydrogen was passed. The arsenic trisulphide was then filtered through a filter moistened with hydrochloric acid, and was subsequently washed with dilute hydrochloric acid (1:3). Finally, in order not to have to remove the hydrochloric acid with water, the precipitate was oxidised in a beaker with bromine water; the residue was filtered off and washed with ammonia, and to the filtrate ammonia was added. The arsenic was then precipitated with magnesia mixture and allowed to stand for some time (see Fresenius, Quant. Anal. Sixth Edition).—T. L. B.

*Volumetric Determination of Carbon in Iron.* J. Wiborgh. *Berg. u. Hüttenm. Zeit.* **46**, 223 and 233. (Compare this Journal, 1889, 726, and 1890, 16.)

The iron is treated with copper sulphate, and the precipitated copper with the still undissolved iron is dissolved in a mixture of sulphuric and chromic acids. The carbon is there oxidised to carbon dioxide, the volume of which is measured in a burette. In order to obtain correct results it is imperative that the carbon be completely oxidised to carbon dioxide. Hence it is necessary that—

- (1.) In treating the iron with copper sulphate no carbon shall be lost as hydrocarbon.
- (2.) In treating the iron with the sulphuric and chromic acids no hydrocarbons shall be evolved.
- (3.) The iron shall be completely dissolved by the sulphuric and chromic acids.

To obtain complete oxidation without hydrocarbon formation, the solvent must consist of a sufficient quantity of chromic acid dissolved in sulphuric acid of requisite strength, and furthermore the iron must only be treated with such solvent after treatment with copper sulphate. If the iron be treated with sulphuric and chromic acid mixture without previous treatment with copper sulphate, then, be the concentration what it may, hydrocarbons will be evolved, the reason given being that the solution of the iron begins before the acid mixture has attained a temperature at which the chromic acid can complete the oxidation. If, however, the iron be completely disintegrated, the freed carbon is not oxidised until the liquid has reached a tolerably high temperature, near its boiling point; the oxidation is then complete.

The copper precipitated by the iron is not dissolved until the temperature of the acid mixture is sufficiently high to bring about complete oxidation of the carbon. Hence the iron need not be *totally* decomposed by the sulphate; it is only necessary that the coating of copper be sufficiently thick to protect the iron from the action of the acid mixture until a temperature sufficiently high for the oxidation has been attained. Finally, of course, all the iron must be dissolved. The iron used should be sufficiently fine to pass through a sieve of 1.5 mm. mesh.

The apparatus used for the determination is shown in the accompanying figure.

THE DETERMINATION OF CARBON IN IRON.

The test tube *a*, 140 mm. long and 20 mm. in diameter, is used for the solution of the iron. It is fitted with a rubber stopper, through which pass a tap-funnel *b*, and a delivery tube connecting *a* with the burette *c*; by means of the tap *k* communication between *a* and *c* may be shut off. The upper end of the burette is fitted with a rubber stopper, through which pass a tap-funnel *e* and the tube *d*. The distance between *a* and *c* is about 200 mm. The burette has a capacity of about 60 cc. and is conveniently made of the form shown; the lower portion is graduated into .1 cc. or .05 cc. It is provided with a tap *l*, and is connected by the rubber tubing *f*, with the movable flask *g*. The test-tube is enclosed in wire gauze, and may be heated by a burner or spirit lamp. The burette is provided with a water jacket.

Into *a* is introduced 0.2 gm. of wrought iron or steel, or 0.1 gm. of pig iron; 4 cc. of a saturated solution of copper sulphate are added, and action is allowed to proceed for 10 minutes, the mixture being stirred with a glass rod (in cases where an appreciable quantity of hydrocarbon is evolved only 3—4 minutes); 1.2 grms. of crystallised chromic acid is added, the whole is stirred, the glass rod washed with not more than 1 cc. of water, and the tube cooled; connection with the burette is made, the water in the burette being adjusted by the aid of *g* and *e*. From *b* now 8 cc. of sulphuric acid of sp. gr. 1.70 are added drop by drop, and the contents of *a* are carefully brought to the boil. Ten minutes' boiling suffices, after which the whole is allowed to cool for 15 minutes. By now pouring water through *b*, the whole of the gas may be transferred to the burette. The

carbon dioxide may be absorbed by caustic potash added from the tap-funnel *c*. This is the carbon dioxide corresponding to the carbon contained in the iron.

A determination occupies about 45 minutes. The results obtained are very satisfactory.—T. L. B.

*Estimation of Sulphur in Iron.* L. Blum. Zeits. Anal. Chem. 29, 138—139.

It has been stated by Lucien (see this Journal, 1888, 401) that precipitation of sulphuric acid by barium chloride may be carried out in presence of free bromine, and that, therefore, there is no necessity to evaporate down previous to the precipitation. It is here pointed out, however, that in the case of some kinds of iron there is in reality no time saved by omitting the evaporation, for brominated organic compounds are formed, such as, for instance, bromo-propylene (Clötz, Ber. 7, 823), and these compounds separating in oily drops, stop up the pores of the filter and thus impede filtration. By evaporating to small bulk the organic compounds form a resinous film in the evaporating dish, and may be easily removed by ether. Further, it is usual in sulphur determinations to use not only bromine water, but even a solution of bromine in hydrochloric acid; and since Fresenius has shown that the solubility of barium sulphate is increased by the presence of acid, it is in such cases better either to evaporate down or else to neutralise the greater part of the acid by pure sodium carbonate.

—T. L. B.

*Determination of Sulphur in Inorganic Sulphides.* P. Jannasch. J. prakt. Chem. 1890, 41, 566—574.

THE author has already published (this Journal, 1890, 110) a method for determining sulphur in iron pyrites by burning the mineral in an oxidising atmosphere and absorbing the volatile products by bromine; he has now worked out the process for other metallic sulphides. The apparatus shown in the figure is designed to avoid the use of corks or rubber joints as far as is practicable, and to ensure perfect absorption. Not more than 0.6 grm. of the substance to be analysed is weighed out into a large porcelain boat and spread evenly therein so as to expose a large surface; the boat is heated in a combustion tube with an internal diameter of at least 15 mm. in

ESTIMATION OF SULPHUR IN INORGANIC SULPHIDES.

a stream of oxygen (150—200 moderate sized bubbles per minute), the heat being applied first at the end remote from the receiver *a* and regulated according to the rapidity with which the reaction proceeds as indicated by the tendency of the mass to glow spontaneously. *a* is about 203 × 36 mm. and has a capacity of 170 cc.; it contains about 60—70 cc. of bromine water; a like quantity is placed in *b*, and a little as a safeguard in the conical flask *c*. The end of the combustion tube leading into *a* is kept warm from the beginning of the operation to prevent condensation of sulphuric acid. The heating and passage of oxygen has to be continued for half to three-quarters of an hour, the temperature being considerably raised towards the last to decompose any sulphate that may have been formed. After oxidation is

complete, the stream of oxygen may be continued (or one of air substituted) until all cloudiness due to sulphuric acid vapour has disappeared. The contents of the absorbing vessels are then emptied into a roomy beaker, 1 cc. strong hydrochloric acid added and the liquid evaporated until all the bromine has been driven off; so important is this precaution that it is best when time permits to evaporate the whole of the aqueous liquid in a porcelain dish to ensure the absence of bromine. The removal of bromine by means of alcohol is not advisable, as small quantities of ethyl sulphuric acid are apt to be formed. The solution thus obtained, containing the sulphur of the substance analysed as sulphuric acid, is precipitated with a 10 per cent. solution of barium chloride in the slightest possible excess, and the barium sulphate washed by repeated decantation with boiling water. The filtrate is concentrated to precipitate any barium sulphate that may be held up by unremoved bromine.

After this description of the method, the author gives examples of its use with blende, copper pyrites, and antimony ore. With the first, particular care in powdering, and long continued heating are necessary to effect complete oxidation. The residue, consisting of zinc oxide contaminated with ferric oxide and gangue, is well fitted for analysis by the usual methods. The last two oxidise readily, and in the case of the copper pyrites, the rest of the analysis can be performed on the oxides left in the boat; but antimony is volatile to some extent, and a small quantity of the metal passes into the receivers. In consequence, a little tartaric acid, to keep it in solution, should be added before precipitating with barium chloride.

The method has the important advantage of allowing the precipitation of barium sulphate to take place in solutions free from salts of the heavy metals. Its accuracy is shown by the figures quoted in the original. Bromine is somewhat objectionable to work with, and the author hopes to replace it with hydrogen peroxide.—B. B.

*Determination of Cadmium as Sulphide by Precipitation with Sodium Sulphide.* W. Minor. Chem. Zeit. 14, 439—440.

THE substance to be analysed is dissolved in hydrochloric or nitric acid, and the lead precipitated by sulphuric acid. To the filtrate an excess of soda is added, which precipitates cadmium and iron. The precipitate is washed and treated with ammonia, which dissolves the cadmium, and this is precipitated from the filtrate by sodium sulphide. The precipitated sulphide takes some time to dry at 140° C. Or the cadmium may be estimated volumetrically by using a solution of sodium sulphide of known strength, and the hydrated oxide of iron as indicator. The least excess of sulphide is shown by the ferric hydrate turning black (see this Journal, 1890, 417).—A. L. S.

*The Citrate Method of Phosphoric Acid Estimation.* O. Reitmaier. Zeits. f. angew. Chem. 1890, 196—210. (See also this Journal, 1890, 218.)

SINCE this method has been doubtfully remarked on (this Journal, 1890, 219), and since conflicting statements as to the value of the method exist, the author has made a thorough examination of all the principles involved. His conclusions are that—

(1.) Solution in hydrochloric acid for citrate precipitation has the disadvantage that the precipitate obtained always contains silica, amounting to several mgrms.

(2.) Sulphuric acid gives a solution poor in silica, and the silica in this case may be taken as 1 mgrm.

(3.) When small quantities of calcium are contained in the solution (superphosphates), the ignited precipitate always contains several mgrms. of calcium as pyrophosphate, even though tolerable excess of ammonium citrate has been used.

(4.) In presence of manganese salts, gross errors, due to existence of manganese pyrophosphate in the ignited precipitate, may creep in.

(5.) Existence of iron and aluminium oxides in the precipitate is very slight if sulphuric acid solutions poor in silica be used. Even large quantities of iron and aluminium oxides may be present. Presence of these oxides in the solution only renders precipitation slower.

(6.) Slight admixture of magnesia must always be expected in the precipitate. Such admixture is lowest when precipitation is performed in ammoniacal solution (2.5 per cent.  $\text{NH}_3$ ). By precipitating in an approximately neutral solution, and in presence of large quantities of salts of the alkalis, the error may be great.

(7.) Against all these positive errors stands the error (equivalent to 1–2 mgrms. of magnesium pyrophosphate) due to incomplete precipitation of the phosphoric acid.

(8.) In controlling the citrate method by the molybdenum method, the means used for getting into solution must be taken into account.

In using the citrate method for determining in superphosphates the phosphoric acid soluble in water, variation from the result obtained by the molybdenum method should not exceed  $\pm 0.128$  per cent.

When Thomas slag and commercial phosphate are being examined in sulphuric acid solution, too high a result must be expected. This error in the case of solution containing very little silica and manganese may be very small, though no mean error can be given.—T. L. B.

*Detection of Benzoic Acid in Foodstuffs.* E. Mohler.  
Bull. Soc. Chim. 1890, 3, 414–416.

AN exceedingly small quantity of benzoic acid being sufficient for antiseptic purposes, the usual method of precipitating this substance as ferrie benzoate is not available. The following method, based on a colour reaction, is far more sensitive.

If a liquid such as beer for example, is to be examined, 100 cc. are taken, rendered alkaline, and evaporated to a syrupy consistency, then acidified with hydrochloric acid, mixed with clean sand, and extracted three times in succession with 20 cc. of ether; the ethereal solution is allowed to evaporate spontaneously, the residue moistened with 2 cc. of sulphuric acid, and heated to 240° till vapours of the acid are disengaged and the mixture blackens, owing to the destruction of the extractive matters dissolved by the ether; then a few crystals of sodium nitrate are gradually added until the liquid becomes colourless. The mixture is cooled and poured into excess of ammonium hydrate, the presence of benzoic acid being indicated by a yellow colouration, which, on the addition of a drop of ammonium sulphide, passes into brown-red. In this test symmetrical dinitrobenzoic acid is formed, which is reduced by the ammonium sulphide, first to amidonitro- and then to diamidobenzoic acid.—E. B.

*" $\alpha$ -Naphthol-Benzoin," a New Indicator.* R. Zolozicki.  
Chem. Zeit. 14, 605–606.

THE author has found that some of the benzeins (see Dobner, this Journal, 1890, 196) possess the qualities of indicators in a high degree, showing delicate colour-changes with acids and alkalis. The author has made experiments in this direction with  $\alpha$ -naphthol-benzoin which he prepares in a way somewhat different from Dobner, as follows:—2 mols. of  $\alpha$ -naphthol and 1 mol. of benzyltrichloride are diluted with benzene, allowed to stand for 24 hours, and then gently heated to 30–40° C. Benzyltrichloride in excess and benzene are subsequently evaporated. The substance is purified by dissolving it in dilute caustic soda, and afterwards precipitating it with hydrochloric acid. This has to be repeated several times, and the operation is finished by washing with water.  $\alpha$ -naphthol-benzoin, thus prepared, consists of a reddish-brown powder, soluble in very dilute alkalis with an intensely green colour, which changes to a reddish-yellow if dilute acids are added. Carbonic acid produces the same effect, the indicator being very sensitive to this gas. It is dissolved in alcohol, assuming a reddish-yellow colour. The author states that the results of his experiments show that  $\alpha$ -naphthol-benzoin belongs to the same group as

phenolphthalein, and that it is of similar sensitiveness as an indicator. Therefore, it can always be applied in volumetric analysis instead of phenolphthalein, carbonates only excepted, because its sensitiveness to the last-named salts is so great as to produce a change of colour before an acid salt is formed. But in most other respects,  $\alpha$ -naphthol-benzoin shows exactly the same properties as phenolphthalein. It may be applied in the following way: 10 to 20 drops of an alcoholic solution of 1 per cent. strength are added to the liquid to be analysed volumetrically; the titration is continued until a drop of the standard solution produces a change of colour from green to orange if standard acid, and from orange to green if standard alkali is added. Acids give a more precise reaction than alkalis. It may be mentioned as an advantage of this new indicator, that the colour-changes are also discernible in artificial light.—H. S.

*Pyrrrol, a Sensitive Reagent for a Group of Etheral Oils.*  
A. Ihl. Chem. Zeit. 14, 438.

THE author has previously observed that pyrrrol is a sensitive reagent for lignified tissue, and he finds that it also gives characteristic colours with such derivatives of allylbenzene, as cinnamic aldehyde, eugenol, safrol, anethol.

A dilute alcoholic solution of cinnamic aldehyde gives, with an alcoholic solution of pyrrrol and concentrated hydrochloric acid, first a yellow-red colouration, changing to dark red, and ultimately a dark precipitate.

In the same way melkenol gives a carmine-red colouration, pimentol also a carmine-red, sassafrasol a rose-red, esdragonal a carmine-red, and anisol and sternalisol a yellow. (This Journal, 1889, 421; and 1890, 555.)—A. L. S.

*The Detection of Olive Waste in Pepper.* Pabst. Monit. Scient. 1890, 470.

THE author recommends for this purpose either dimethyl-para-phenylenediamine which has been proposed by Würster for the detection of ground wood in paper, or thalline, which is used to stain the ligneous tissues of plants. The former reagent is conveniently prepared as follows:—Ten grms. of commercial dimethylaniline are mixed in a porcelain dish with 20 grms. of pure strong hydrochloric acid. 100 grms. of broken ice are next added, and then, little by little, with constant stirring, a solution of 7 grms. of sodium nitrite in 100 cc. of water. After half an hour 30–40 grms. of hydrochloric acid and 20 grms. of tin-foil are added. The reduction is allowed to go on for an hour, when the tin in solution is precipitated by means of metallic zinc. The decanted and filtered liquid is treated with a slight excess of sodium or potassium carbonate, and the turbidity thus produced is redissolved by the addition of acetic acid. Finally, 10 grms. of sodium bisulphite are added, and the whole is diluted to 2 litres. In testing pepper, 1–2 cc. of the above solution are placed in a shallow dish, and a pinch of the pepper is sprinkled into the solution. In a few minutes the particles of olive waste assume a splendid red-carmine colour; whilst the grains of pepper remain unaltered or are coloured only a faint pink. If some water be now added, the heavy particles of olive fall to the bottom, and collect together, when they may be detected with the greatest ease. Of course, any other ligneous tissue present in the pepper, such as ground nut-shells, will also be coloured red by this reagent. Thalline sulphate, in  $\frac{1}{2}$  per cent. solution, stains the olive particles a beautiful orange, easily detected. The colour, however, takes longer to develop than the red produced by the preceding reagent, and the solution of thalline sulphate does not keep well. The colours given to olive waste by the above reagents are soluble in water after some time, the waste itself assuming a brownish or blackish colour.—H. T. P.

*Experiments on Gum Arabic and Gum Senegal.* L. Liebermann. Chem. Zeit. 14, 665–666.

GUM arabic is often adulterated with gum Senegal, the latter being sometimes sold in its stead. If the gum has not been powdered, the appearance is sufficient to show

which variety is chiefly present. Gum arabic forms round or irregular masses, varying in colour from colourless to brown, which reflect light strongly, almost appearing to be crystalline. Gum Senegal is usually colourless or pale yellow, with a surface resembling ground glass, the pieces cylindrical or worm-like. It occurs occasionally in round masses resembling a mulberry.

On dissolving either gum in water, only small particles of wood are left, which, according to Kramsky, are usually red in the case of gum arabic, but black with gum Senegal. Other gums, cherry, for example, are only partially soluble in water, leaving a swollen residue, which only dissolves after long digestion.

With potassium hydrate, and a few drops of copper sulphate solution, both gums give a blue precipitate, which, in the case of gum arabic, is larger in quantity, coherent, and rises to the surface, while the other is more flocculent and remains diffused in the liquid. The precipitates are only slightly soluble on heating, and are not reduced even by boiling. Dextrin yields a similar precipitate, easily soluble on warming, and which is completely reduced on boiling for some time. On prolonged heating with dilute potassium hydrate, solutions of gum arabic and of dextrin become amber coloured, those of Senegal are only slightly coloured.

Mixtures of gum arabic and Senegal behave to the copper test like Senegal alone, but with potassium hydrate they assume the amber colour. Mixtures of gum arabic or Senegal and dextrin with the copper test behave like gum arabic alone, and if the amount of dextrin is not too small, reduction takes place on boiling. When only small quantities of dextrin are present, the copper precipitate after thorough warming may be filtered off, and the filtrate boiled; reduction will then take place. When all three substances are present, the precipitate should be washed, dissolved in

dilute hydrochloric acid and a large excess of alcohol added. The precipitated gum is allowed to settle for a day, washed with alcohol, dried, and examined as above.

Gum arabic may be systematically examined in the following manner:—The powdered substance is treated with luke-warm water; a gelatinous residue indicates other gums. The aqueous solution is mixed with an excess of potassium hydrate and a few drops of copper sulphate, warmed and filtered, and the filtrate examined for dextrin by boiling, the precipitate being tested as above.

It is usually stated that gum Senegal is more hygroscopic than gum arabic, but when dried at 105° C., gum Senegal lost 13.39 per cent. of water and gum arabic 14.56, and on exposure to moist air for 24 hours, the former gained 6.15 per cent., the latter 6.34.—F. H. L.

#### *Thermo-Chemical Investigations on Silk.* L. Vignon. Bull. Soc. Chim. 1890, **3**, 165—110.

SIXTEEN skeins of silk (cultivated), of the same quality, reeled and spun under precisely similar conditions, were dried and weighed, and then half of them boiled-off, re-dried and weighed, the average loss in weight being 22.91 per cent. The ungummed skeins were left exposed to the air in the laboratory to cause them to regain their normal amount of moisture; then they were immersed in certain solutions in a calorimeter, the skeins of raw silk being similarly treated. The liquids employed in the calorimeter consisted of seven normal solutions as follow: potassium, sodium, and ammonium hydrates, sulphuric, hydrochloric, and nitric acids, and potassium chloride, along with distilled water, in each case 500 cc. being used.

The results are shown in the table below:—

Reagents.	Raw Silk.		Ungummed Silk.

\* Alkalies act on raw silk, removing some of the silk-gum.

The total numbers of heat units evolved are 6.00 in the case of ungummed silk and 6.65 in that of raw silk; sericin, consequently, causes the evolution of more heat than does fibroin, although the two bodies are chemically closely related; on calculation, it is found that sericin evolves 1.47 times more heat than fibroin. The author hopes that further investigations in this field may be of use in extending our knowledge of the theory of dyeing.—E. B.

*Eucalyptus Oil.* Schimmel and Co. Zeits. Anal. Chem. **29**, 222—223.

See under XX., page 761.

#### *On the Examination of Wax.* H. Röttger. Chem. Zeit. **14**, 606—607.

THE determination of the specific gravity of wax may in some cases be used as a preliminary test, pure bees-wax having an average specific gravity of 0.960. If the substance in question differs considerably from this, an adulteration is proved. Hübl's test (Chem. Zeit. **13**, 1375) is the most reliable for the quantitative and qualitative examination of wax, and the author having most carefully examined the various other methods, has come to the conclusion that the result in most cases is very unsatisfactory. Two methods only are mentioned which give good results, if the adulteration of wax with stearic acid has to be proved.

1. Fehling's method (Dingl. Polyt. J. **147**, 227). He recommends boiling the substance four or five minutes with

20 times its weight of alcohol, and afterwards letting it stand for several hours. Then it is filtered and the filtrate mixed with water. If the wax was pure, the liquid remains perfectly or almost transparent, but if it was adulterated with stearic acid, it loses its transparency, a reaction which is plainly perceptible even if the adulteration amounts to as little as 1 per cent. of stearic acid.

2. Benedikt (*Analyse der Fette*, 291) advises boiling the substance with sodium carbonate. The solution on cooling becomes solid when sodium stearate is present. This method is also reliable, but not so exact as that of Fehling.

The two methods just mentioned, together with Hübl's and the specific gravity test, seem to be all we have practically to rely upon, to prove adulterations in wax.—H. S.

#### Determination of Mineral Oil in Fatty Oils. A. Grütner. *Zeits. f. angew. Chem.* 1890, 261.

Houx's method (this *Journal*, 1888, 696), consisting in saponifying the mixture of mineral and fatty oil and extracting the dried soap with chloroform, has given excellent results in the hands of the author save when the proportion of mineral oil is large, in which case a pasty mass is formed, difficult to extract. He accordingly modifies it thus: 2—3 grms. of the oil are saponified in a porcelain basin 8—10 cm. in diameter with 20 cc. of alcoholic soda containing 20—25 grms. of caustic soda in a litre of 95 per cent. alcohol. After the alcohol has been driven off, sand (purified by treatment with hydrochloric acid) is stirred in, and the mass wrapped in filter-paper and extracted with chloroform in a Soxhlet's apparatus. The purification of the sand is necessary, as any lime present in it would form a lime soap which is soluble in chloroform. The chloroform is best purified by distillation with strong sulphuric acid. The results of the method are accurate.—B. B.

#### Determination of the Solidifying Point of Lubricating Oils.

A. Martens. *Mitt. k. tech. Versuchst.* 1890, 53—71.

A COMPARISON was instituted between the various forms of apparatus in use by several Government railways for determining the solidifying points of lubricating oils, and the method adopted by the Versuchsanstalt (this *Journal*, 1889, 423).

(1.) The oil is cooled by exposing the test tube containing it to a bath of ether through which a stream of air can be drawn, and its condition judged by inclining the tube. The method is unsatisfactory, the cooling with ether being a grave defect, as it is costly, dangerous, disagreeable, and, unless the air be previously dried, liable to cause stoppage by blocking the tubes with ice. The time commonly allowed for cooling is also insufficient (the importance of this condition is shown in the preceding abstract), and results compare unfavourably with the standard method of the Versuchsanstalt.

(2.) The oil is solidified in a freezing mixture, removed therefrom, and the temperature at which it begins to flow under a head of 30 mm. of oil noted. This also met with disapproval, wide discrepancies occurring with slight alterations of the conditions of experiment; besides it does not determine the *solidifying* point but that of incipient fusion.

(3.) The apparatus and method are of a character similar to those of (2), and the same objections hold good. The use of ether as a cooling agent leads to the presence of the disadvantages mentioned under (1).

(4.) Since the description of the standard method of the Versuchsanstalt appeared, a new process has been devised, the apparatus for which is illustrated herewith. It may be briefly described thus:—The oil is placed in a U-tube (Fig. 1) and exposed to a known and constant low temperature by the use of a bath of one of the frozen salt solutions prescribed for the standard method (this *Journal*, 1889, 423), and its condition ascertained after a sufficient period of cooling by exposing it to a pressure equal to a column of water 30 mm. in height. Fig. 2 shows a convenient method of obtaining a constant pressure for this purpose. A gas-holder *a* is connected with a tube (having its end

turned up and rounded as shown in Fig. 3) immersed to such a depth in any suitable fluid (e.g. a non-volatile oil) that air from the gas-holder can escape from it when the water-manometer *c* shows a greater pressure than 30 mm.; this device is necessary to prevent fluctuations in the pressure due to alterations of temperature. A water pump may be substituted for the gas-holder. In carrying out a number of determinations a set of U-tubes may be held by the stand shown in Fig. 4, the design of which is obvious. The frame carrying them can be lifted bodily out of the containing vessel. The whole of the metal parts of the apparatus are nickel-plated to decrease their liability to corrosion from the salts used. The concordance of the results obtained by this method and its ease of working make it preferable to those previously described.

Fig. 1.

Fig. 3.

Fig. 2.

Fig. 4.

(5.) The simple plan of cooling the oil in a capsule immersed in a freezing mixture, stirring it with a thermometer, and noting the change of state it undergoes, is used, and has little to recommend it, the serious personal equation (to get rid of which is largely the object of most of the more complex methods) being particularly objectionable.

(6.) The standard method of the Versuchsanstalten has already been described (this Journal, 1889, 423), and does not need repetition. It has been found lately that a large increase in the width of the vessel in which the oil is cooled causes it to remain fluid at a lower temperature than under normal conditions.—B. B.

*The Melting and Solidifying Points of some Fatty Bodies and Mixtures.* A. Terrell. Bull. Soc. Chim. 1890, 3, 195—200.

See under XII., pages 743—744.

*The Density of Resin Oil and of Essence of Turpentine.* A. Renard. Monit. Scient. 1890, 469.

The author has determined the density and coefficient of expansion of these oils, so that their density observed at any convenient temperature may be reduced to their density at 15° C. by means of the formula—

$$D_{15} = D \mp Ct$$

in which  $D_{15}$  = density at 15° C.;  $D$  = density observed;  $t$  = difference between the temperature of observation and 15° C.

$Ct$  is added to  $D$ , when the temperature of observation exceeds 15° C.; and it is subtracted from  $D$  when the temperature is below 15° C.

#### *Pale Resin Oil (First Distillation).*

 $D_{15} = D \mp 0.000789 t$

—H. T. P.

*Estimation of Anhydrous Glycerol in Commercial Glycerol.* E. Deiss and C. Deiss. Les corps Gras Industr. 16, 293.

THE method depends upon the fact that the absorption of water by a constant weight of a mixture of glycerol and pure phenol is proportional to the degree of concentration of the glycerol. Into a flask of about 100 cc. capacity are introduced exactly 10 grms. of the glycerol under examination, and 6 grms. of pure crystallised phenol, which has been melted; the whole is well mixed and allowed to cool. A solution is made up containing 50 grms. of pure crystallised phenol to 1,000 grms. of water. This solution is carefully run from a burette into the flask containing the above mixture of the glycerol and phenol until permanent milkiness is just attained. In the

case of anhydrous glycerol 28.15 cc. of this phenol solution are required; and for every per cent. deficiency in the glycerol at the same temperature (not stated) 0.39 cc. less is required, as experiments have conclusively shown.

If  $q$  be the number of cc. of phenol solution used, the percentage of glycerol contained in the sample examined is—

$$100 = \frac{28.15 - q}{0.39}$$

For a temperature of 11° C. the percentage is —

$$100 = \frac{21.40 - q}{0.28}$$

In order not to have to find the equations corresponding to various temperatures the authors recommend that all experiments should be carried out at a temperature of 11° C. by surrounding the flask with water kept at this temperature. Presence of extractive substances, salts, and colouring matter are said not to affect the result. The method gives very good results with commercial glycerol.

—F. L. B.

*Estimation of Starch-Flour in Grain.* Z. von Milkowski. Zeits. Anal. Chem. 29, 134—136.

ASBÖTH first removes fat by extraction with ether (this Journal, 1889, 574), and then estimates the starch in the product by the baryta method (this Journal, 1887, 608). The author has made comparative experiments by extracting with carbon bisulphide, and his results agree perfectly with those of Asböth.

Mäcker's method is as follows:—3 grms. of finely powdered substance are made into a paste with 50 cc. of water in a water-bath at 100° C.; the whole is cooled to 70° C., and 5 cc. of malt extract (100 grms. of green malt to 500 cc. of water) are added, the temperature being kept at 70° for some minutes. To prevent darkening of the solution a 1 per cent. solution of tartaric acid must be added. The liquid is next subjected to a pressure of three atmospheres, is cooled and has 5 cc. of malt extract added to it, after which it is again warmed to 70° C., and at the end of about 20 minutes the starch is completely dissolved. A portion of the filtered solution is now inverted with hydrochloric acid (sp. gr. 1.125), and in this by means of Fehling's solution the sugar, and indirectly the starch, is estimated. Allowance must be made, of course, for the 10 cc. of malt extract added.

Results obtained by the author by this method and by Asböth's method agree exceedingly well together. Methods which depend on direct inversion by acids cannot be reliable, since other substances, such as cellulose and pectin, are calculated as starch in such cases.—T. L. B.

*Determination of Nitrogen in Manures.* E. Aubin and J. Quenot. Bull. Soc. Chim. 3, 1890, 322—326.

THE authors first cite experiments to prove that, whether sugar, or a mixture of sulphur and calcium oxalate, be added to the soda lime, the whole of the nitrogen of nitrates is not obtained as ammonia by the combustion process, and that the addition of oil in the Kjeldahl process is open to the same objection. A mixture of sulphuric acid, phenylsulphuric acid, and zinc gives a much better result; but still there is a loss, 0.0667 grm. N being obtained from potassium nitrate instead of 0.0692 grm. If the Kjeldahl process be employed on an organic manure containing nitrates, some of the nitrate is reduced; and if a mixture of ammonium salt and nitrate only be analysed by this process, some of the ammoniacal nitrogen is lost by oxidation.

The best way to obtain the total nitrogen (organic, ammoniacal, and nitric) by the Kjeldahl process is to use a mixture of 30 cc. sulphuric acid, 3 cc. phenylsulphuric acid, 1 grm. zinc, and 0.5 grm. mercury with the manure; but even then there is a slight deficiency in the nitrogen obtained. Attempting to first eliminate the nitric nitrogen, by digestion with ferrous chloride, the authors find the ammoniacal nitrogen rendered too low. Ferrous sulphate gives better results.

The authors recommend, however, the following process, which permits of the determination of the organic and ammoniacal nitrogen, together or separately, the nitric nitrogen being determined in a fresh portion by Schloesing's process (see this Journal, 1884, 379, and 1888, 692). One gram. of the manure is exhausted on a filter by 30--40 cc. of a 2 per cent. solution of tannin, by which the nitrogenous organic matters are rendered insoluble, if not already so. The residue and filter, deprived of nitrates, and of most of the ammonium salts, are attacked by the Kjeldahl method, and when ready for the final distillation, the filtrate is remixed with the contents of the flask, and the organic and ammoniacal nitrogen determined together.

To determine them separately, it suffices to remove the ammonium salts entirely by the tannin solution; and this can be done even when ammonio-magnesium phosphate is present, by digesting 1 gram. of the manure for 15 hours with 0.7 gram. tannin and 150 cc. salt-water. The residue is treated by Kjeldahl's process for the organic nitrogen, the filtrate by distillation with sodium hydrate for the ammoniacal nitrogen, and the nitric nitrogen is determined in a fresh portion by Schloesing's process.—J. M. H. M.

*The Vacuum Method of Drying Barley and Malt, with a Direct Determination of the Extract in Beer and Worts.*  
C. N. Rieber. Zeits. f. d. ges. Brauw. **13**, 97.

See under XVII., page 756.

#### PATENT.

*Apparatus for Estimating the Quantity of Glucose or Grape Sugar in Fluids.* A. W. Gerrard, London, Eng.  
Pat. 18,856, November 25, 1889. 4d.

The apparatus consists of a burette, from which the sugar solution is run in the ordinary way into Fehling's or any other copper solution. In working with this apparatus it is necessary always to use such an amount of Fehling (say 10 cc.) or other copper solution as is exactly equivalent to 0.05 gram. of glucose; and further, the sugar solution must be diluted to 20 times its volume. Under these conditions, the correct percentage of sugar in the original solution may be read off direct from the burette.—A. J. K.

### New Books.

CHEMISCH-TECHNISCHE ANALYSE. HANDBUCH DER ANALYTISCHEN UNTERSUCHUNGEN ZUR BEACHTSICHTIGUNG DES CHEMISCHEN GROSSRETRIEBES UND ZUM UNTERRICHTE. HERAUSGEGEBEN VON DR. JULIUS POST. Zweite vermehrte und verbesserte Auflage. Zweiter Band. Zweite Lieferung. 1890. Braunschweig: Friedrich Vieweg und Sohn. London: H. Grevel and Co., 33, King Street, Covent Garden.

This volume forms part II. of the second volume of Post's great work on Chemical-technological Methods of Analysis. (See this Journal, 1888, 872.) The work is illustrated with 77 excellent engravings and the volume is mainly devoted to the subjects of Starch, Dextrin, Sugar and the Fermentation Processes, and products such as Wine, Beer, Spirits, and Vinegar.

Under Spirits and Vinegar, also Wood Spirit appears and receives full treatment. The methods of Krell, Krämer and Grodzki, and Bardey and Bordet, are described, for estimating the Methyl Alcohol, Acetone, and other constituents.

The Chemical and Chemico-physical Methods for Testing Sugar-juices, Syrups, &c., are very fully given and well illustrated, and the best methods for estimating the Constituents of Wines and Spirits are described in considerable detail.

### Trade Report.

#### TARIFF CHANGES AND CUSTOMS REGULATIONS.

##### PHILIPPINE ISLANDS.

##### Customs Tariff.

*Note.*—Kilog. = 10 Hectogrammes = 2.204 lb. avoird. ;  
litre = 22 Imp. gallons.

The following is a statement of the rates of Customs duty now levied on imports into the Philippine Islands:—

Classification of Articles.	Rates of Duty now leviable.	
	Pes. Cts.	
Mineral oils .....	100 kilos.	1.10
Wax .....	Kilo.	0.04
Wax, worked .....	"	0.12
Copper, brass, zinc .....	"	0.05
Matches of any kind .....	"	0.05
Caoutchouc, manufactured .....	"	0.22
Perfumery of any kind .....	"	0.10
Hides tanned .....	"	0.12
Pharmaceutical and chemical products not prohibited by sanitary regulations .....	8 % ad val.	
Candles .....	Kilo.	0.05

The importation of the following articles is prohibited:—

(a.) Articles of food containing materials injurious to health (fuchsine, salicylic acid, &c.).

(b.) Pharmaceutical products the composition of which is kept secret (such as Holloway's pills).

For the importation of explosives, such as gunpowder, dynamite, &c., a special permit is required.

The importation of the following is only permitted to certain individuals:—

Opium imported by the farmer of this tax or by chemists in small quantities and for medicinal purposes.

The following are free of import duty:—Manures, lime, cement, plaster.—*Board of Trade Journal.*

#### EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

##### BRITISH GUIANA.

##### Drug Exports.

Among the exports from the colony during the years 1887 and 1888 were the following articles of interest to druggists:—

	1887.	1888.
Gum (Balata) .....	£ 3,428	£ 14,069
Gum (other) .....	2,021	479
Isinglass .....	338	107
Arrowroot .....	153	25

*Balata and India-rubber.*

It is gratifying to record the growth of another industry in the collection of balata. The legislation of 1887, placing the collection of this and other gums on a proper footing, has been eagerly taken advantage of, and 25 balata licences were issued during the year, the result of which has been to increase the export of this useful article from 80,942 lb. in 1887 to 248,484 lb. in 1888.—*Chemist and Druggist*.

## CAPE COLONY.

*Drugs and Chemicals.*

In 1888, drugs and chemicals were imported into the Cape Colony to the value of about 69,760/.

*Soap.*

There is a duty of 4s. 2d. per cwt. on foreign soap imported into the Cape, and this protection accounts for the existence in the colony of 10 soapworks, of which the two most important ones are those of Messrs. Low and Smithers. Notwithstanding the existence of this industry, the colony imports a considerable quantity of common soap, especially for wool-washing. The indigenous product sells at 9s. to 10s. per  $\frac{1}{2}$ -cwt. box, while the foreign article is slightly higher in price. The imports in 1888 were:—From England, 5,261,354 lb.; from Natal, 19,560 lb.; from the United States, 35,650 lb.; from South Australia, 10,046 lb.; from Germany, 13,524 lb.; from the Argentine Republic, 80 lb.—*Ibid.*

## CHINA.

*Aniline Dyes.*

It is worthy of remark that no aniline dyes were imported into Newchwang last year, says the British Consul in that city. It is said that the Chinese have come to dislike these dyes, and to find that those which they make themselves are more serviceable and cheaper in the end. So they are returning to the use of sapan-wood and their own dyestuffs. On the other hand, the Consul at Kewkiang observes that dyes, principally of German manufacture, continue to form a considerable article of trade. Many of the colours chosen are not in the best taste, magentas and aniline greens, blues, and pinks being the favourite shades.

*Chinese Camphor.*

The camphor trade of Formosa does not show any signs of improvement. The restrictions formerly imposed by the Government monopolists are nominally removed, but the difficulties and risks of getting the camphor down to the coast are so great that foreigners are not inclined to engage in the trade, notwithstanding the very high prices that have ruled in the Hong Kong market lately. Chinese traders decline positively to deliver camphor at the port, and do not care much about touching the business at all. Practically, it may be said, the monopoly still exists, and the entire export of 1889 was only 709 cwt.

*Turkey Opium.*

The consumption of Turkish opium in certain parts of China is largely on the increase. In the island of Formosa, for instance, it has almost entirely replaced Indian opium, as the following figures will show:—

—	Indian.	Persian.	Turkey.
	Cwt.	Cwt.	Cwt.
Imports in 1889 .....	445	25	1,987
„ 1888 .....	618	24	1,707

Eight years ago Indian opium from Benares, with a small quota of Malwa, took about 50 per cent. of the trade, the remaining moiety being divided between Persian and Turkey. Persian and Malwa have now practically disappeared; Turkey monopolises about 80 per cent. of the demand, leaving only 20 per cent. to Benares.

*Native Opium.*

It is also certain that the native-grown drug is steadily gaining a footing in Formosa, but as it does not pass through the foreign Customs statistics are not obtainable; but it is well-known that there is a steady re-export of foreign opiums in native junks to the mainland, where they are exchanged for the opiums of Szechuan and Yunnan, which are then brought back to Tamsui for local consumption.

It is estimated that 80,000 lb. of Chinese-grown opium were imported in that city during the year 1889; the most popular coming from Tang Shan Hsien and Feng Hsien, in the neighbouring province of Kiangsu. A Szechuan firm has just set up business in Waku as well, and there is every probability of the native drug, which is now far better prepared than formerly, besides being only about half the price of the Indian, coming more and more into favour.

*Drug Exports.*

The following figures show the export of drugs during the years 1888 and 1889 from Ichang, the Chinese inland trade centre on the Yangtze river, which is the principal place at which goods brought from the interior pass into commerce for foreign countries. The question of the establishment of regular steam navigation with Ichang recently led to the conclusion of a special treaty with China:—

—	1889.		1888.	
	Lb.	£	Lb.	£
Medicines .....	..	46,613	..	79,380
Musk .....	4,056	71,856	4,269	85,537
Nuttsalls .....	907,708	12,786	371,656	7,911
Rhubarb .....	308,118	13,460	260,227	11,065
Safflower .....	104,423	11,062	117,556	12,431
Wax, white .....	1,543,115	95,211	2,081,041	117,540

*White Wax.*

The diminished export of white wax is due to low prices ruling in Shanghai for most of the year; and still it hardly pays to export it. Over 40,000 lb. of this substance was sent to Peking for use at the Emperor's marriage, tallow and colours being the other contributions from Szechuen.—*Ibid.*

## FRANCE.

*Dyewoods in Havre.*

The large decrease in the quantity of dyewoods imported into Havre in 1889 must be put down to the disturbed state of the island of Hayti, and to the great difficulty of transport from the interior where the wood is now procured. Thus fustic showed a decrease of 11,500 tons. It must also be noted that three Havre manufacturers have erected works at Riga for extracting dyes, and that they receive the raw material there direct. This step has been necessitated owing to the increase in the Russian Customs duties on dyewood extracts.

*Oils and Oil Seeds in Marseilles.*

The imports of oleaginous seeds into Marseilles for the year 1889 amounted to 314,265 tons, against 278,527 tons in the previous year. The crops of ground-nuts in the French colonies (Coromandel coast) were very large, about 110,000 tons, and the imports of this article alone attained 97,374 tons, against 73,061 tons in the previous year. Likewise of coprah (produced chiefly in the South Sea Islands, Straits Settlements, and Java) Marseilles received 46,000 tons, against 35,500 tons in the preceding year. The whole 314,265 tons of oleaginous seeds have been crushed by the local mills, and the oils produced met with a ready and remunerative sale to local soapmakers, as well as for export, showing a very prosperous condition of this great industry.

The coprah and palm-kernel trade continues to increase steadily, and the quantity of coprah and palm-kernels crushed in Marseilles in 1889, excluding the old stocks lying over from 1888, exceeded 80,000 tons, yielding upwards of 10,000 tons of concrete oil, chiefly consumed by local soap-mills. Imports of palm oil amounted to 12,039 tons, against 11,551 tons in 1888. The French Government has granted a large subsidy to one of the leading companies of steamers to run a regular line to and from the different ports on the West Coast of Africa, which is a further facility in the way of extending the direct imports of palm-oil and palm-kernels, the chief articles exported from that country.

The oil-seed crushers also had a sound and profitable trade throughout the year, their export trade having attained 13,110 tons against 36,783 tons in 1888.

In soap also there was an increase of 1,700 tons, the year's exports being 10,184 tons, against 8,470 tons in 1888. The quantity of candles exported from Marseilles amounted to 4,100 tons, against 3,967 tons in the previous year. This industry is very prosperous, and tends to increase further.—*Ibid.*

#### ITALY.

##### *Chemicals.*

Acids and chemicals used for the extermination or prevention of phylloxera, such as sulphate of copper, are purchased in large quantities. Pigments for house-paintings are also in demand, as well as a few products for leather dressing and dyeing, of which branches of industry the city of Cagliari is an important centre; but these goods are mostly furnished by other parts of the island, where the principal raw materials are found in abundance.

#### JAPAN.

Consul Playfair, of Hakodate, reports that last year's exports of sulphur amounted to 14,421 tons, valued at 34,630*l.*, as against only 3,609 tons in the previous year. Prices showed no material change. One of the causes of the smallness of the exports in 1888 was that freights were low, and in consequence tonnage was not available.

#### NORWAY.

##### *Cod-liver Oil.*

The total exports of cod-liver oil have been :—

	1884.	1885.	1886.	1887.	1888.
Tons.....	12,500	14,700	16,900	16,000	20,200
Value..... <i>£</i>	317,000	290,000	285,000	256,000	312,000

#### RUSSIA.

##### *The Petroleum Trade.*

The exports of petroleum products from Batoum, the port through which the output of the Baku petroleum wells is brought into commerce, has grown to 649,085 tons (value, 3,023,300*l.*) in 1889, from 450,326 tons (value, 1,724,446*l.*) in 1888. All other branches of business, especially those relating to imports, occupy a very subordinate rank in the local market. On the other hand, the import of such foreign goods as are absolutely required for the petroleum trade—as, for instance, tin plates, caustic soda, &c.—has become a business of considerable importance. If it were not for the demand for such articles there would be scarcely any cargoes for ships arriving in Batoum to load petroleum. The imports of caustic soda are about 4,000 tons per annum. Although the aggregate quantity and value of the petroleum trade considerably surpassed that of any preceding year, the business, so far as profitability goes, was upon the whole less satisfactory. Such firms trading in petroleum who at the same time are owners of productive petroleum wells must have found the year an exceptionally profitable one, because of the great rise in the price for crude oil; but

the commercial community as a body have not been able to realise profits in any way proportional to the expansion of business.

#### SPAIN.

##### *Quicksilver.*

The shipments of quicksilver (all of which goes to England) from Corunna, in 1889, show a large increase over the previous year, the value being returned as respectively 5,864*l.* and 11,600*l.* This quicksilver is produced by the Asturian mines in the north of Spain. These are much less important than the Almaden mines in the south; but, as the Asturian mines are being exploited much more extensively now, the quantity they produce is likely to be larger in future.

##### *Drugs for Barcelona.*

The total weight of manufactured goods imported by sea into Barcelona in 1889 was 52,742 tons, against 51,862 tons in 1888. There was an increase in the importation, among other goods, of colouring extracts, chemical and pharmaceutical products, soap, and india-rubber goods. About 17,790 tons, or one-third of total amount, came from Great Britain, and consisted, to a great extent, of drugs and chemicals. The imports by land included 10,361 tons of drugs, chemicals, and colours.

##### *Sulphate of Copper.*

Great attention has been given to the question of the use of sulphate of copper in vine disease in the autumn of 1889, and a committee of investigation arrived at the conclusion that the poor results shown for the use of sulphate of copper had been owing to the inferior character of the article that had been employed. It was resolved that the committee should import a quantity of pure sulphate of copper, and supply it to municipalities in the province at cost price, import duty being remitted by the Government. The total amount asked for by the entire province, however, was only 45 tons, and a contract was made for the supply of this quantity to the committee by Messrs. Vivian and Sons, of Swansea. It is thought that other municipalities will avail themselves of this system of obtaining pure sulphate of copper at a low rate as soon as its advantages come to be known.

#### UNITED STATES.

##### *Californian Quicksilver.*

The total production of quicksilver in California in 1889 amounted to 25,650 flasks, as against 33,250 flasks in 1888. The average price for the year is 9*l.* per flask.—*Chemist and Druggist.*

#### WESTERN AUSTRALIA.

##### *Sandalwood.*

The exports of sandalwood from the colony in 1889 were 4,470 tons, valued at 33,525*l.*—*Ibid.*

## MISCELLANEOUS TRADE NOTICES.

#### HENEQUEN PRODUCTION IN YUCATAN.

In the State of Yucatan, in consequence of stagnation in the henequen industry, owing to the conflicting interests of producers, the *Mexican Financial Review* reports the existence of distress among the poorer classes. The large profits obtained by the growing of henequen had induced land-owners and others to neglect the production of cattle wheat, and other primary necessities of life, with the result that food supplies had been greatly enhanced in price to the inhabitants of that part of the Republic.

Of the 240,000 packages of henequen sent to the United States during the past year, about 225,000 went into consumption, and the balance remained on hand for the

present year. In view of the increased area of cultivation which has since been developed, the supply during the present year cannot fall far short of 260,000 packages. During the months of January and February only about 35,000 were exported, which, added to the surplus from the previous year, would make a total of about 50,000 on hand in the United States at that time. According to data received up to March 15th, the stock on hand in the United States was about 30,000, so that only about 20,000 had gone into consumption. There is, therefore, every prospect of an increased supply being encountered by a considerably diminished demand.—*Board of Trade Journal*.

#### GALICIAN PETROLEUM INDUSTRY.

*Bradstreet's* for the 31st May has the following:—

Although still of very moderate proportions, and but little heard of outside of Austria, the petroleum industry of western Galicia is said to be older than the Pennsylvania industry by nearly 10 years. The advance in the world's markets of the American product and the extraordinary growth of the supply acted as a discouraging feature in the development of the Austrian deposits just as the use of petroleum as an illuminating material began to be understood there. A State investigation, made public in 1880, according to a writer in the Vienna *Neue Freie Presse*, showed that the Galician oil-producing region embraces almost the whole northern slope of the Carpathian Alps from New Sandee to the Bakovina, and is of far greater extent than that of Pennsylvania. The strata are pretty regular, and the surface indications of the presence of oil are well marked. Two American explorers, Messrs. Macgarvey and Berghien, who discarded the old methods of trenching and adopted the most modern American tools for boring, seem to have met with considerable success, and to have trained the native workmen till they are in every way capable of carrying out the work on the most approved lines; but in spite of this capital seems to have fought shy of the industry, and only some small works, but nothing on any large scale, has been attempted. The quality of the oil raised in Galicia varies with the strata containing it.—*Ibid.*

#### BAKU PETROLEUM TRADE.

Official statistics published by the Russian Ministry of Finance show, says the *Levant Herald* for the 20th June last, that in the first quarter of this year the total shipments abroad of petroleum and its products derived therefrom, from the Baku district, amounted to 12,733,432 poods, against 9,512,517 poods during the corresponding period of 1889, the increase being, therefore, 3,220,885 poods, or over 30 per cent. In these totals refined petroleum figured for 9,413,281 poods in 1890, and 7,917,268 poods in 1889, or an increase of 1,496,013 poods, being about 20 per cent. During the same time 17,431,476 poods of petroleum of all kinds, 2,018,653 poods refined, and 14,041,242 poods residual products were despatched to European Russian markets; whereas in the same period last year this movement amounted only to 7,617,073 poods of which 980,867 poods refined petroleum, and 6,106,108 poods residual products. To the Transcaucasus 773,754 poods of petroleum of all kinds were also sent, against 477,453 poods in the first quarter of 1889, residual products accounting for 758,206 poods this year, and 470,104 poods last year. The quantity of naphtha extracted and supplied to the factories during the quarter reached 52,744,124 poods, compared with 34,985,713 poods in 1889, the difference in favour of the present year being 17,758,411 poods, or more than 50 per cent.—*Ibid.*

#### PERUVIAN PETROLEUM.

The *Journal de la Chambre de Commerce de Constantinople* for the 14th June says that the discovery of very important petroleum wells in the north of Peru, in the region comprised between Payla and Tumbes (Department of Pima) will be the means of creating a new source of prosperity for Peru. Already for several years past an Italian, M. Paggio, has been working four wells at Zorritos, near Tumbes, but the petroleum was of an inferior quality,

and the refined petroleum was only sent to Lima in small quantities. An American, M. Tivfield, already well known by his works at Baku and on the Red Sea, purchased a few months ago vast deposits situated near Tatará (to the south of Tumbes). Owing to the large amount of capital at his disposal, the workings have assumed considerable importance. Eight wells are at present opened, and the supply of petroleum would appear to be inexhaustible. A factory for refining the petroleum, and another for manufacturing the tin boxes, have been erected.

A joint stock company, with a capital of 200,000*l.*, has just been formed for the working of the Talará deposits, and those which may be discovered in the future. M. Tivfield has ordered from the United States six fast steamers containing tanks for distributing the petroleum on the Pacific coast, and even sending it to Europe. Besides kerosene, the Talará company also exports unrefined petroleum, which is used for the heating of locomotives. The wells have the advantage of being situated near to the port, which is an excellent one.—*Ibid.*

#### DISCOVERY OF MINERAL OIL IN INDIA.

The *Calcutta Englishman* (overland mail) for the 13th May has the following:—

"A discovery of mineral oil has recently been made in the Suliman hills in the district occupied by the Tser Khoyl tribe of Shiranis. The story of its discovery is decidedly interesting. About five years ago, it appears, the Rev. W. Thwaites, a missionary at Dera Ismail Khan, had in his employment a Shirani chowkedar. On one occasion when the regular house servant was away the boy undertook to trim the wall lamps for night use. The smell of the oil struck him as familiar, and he asked what oil was put into these lamps as its smell was exactly like that of an oil that issued from the ground in his own country. He was accordingly told to get some, and in the course of a few days some oil was brought from the hills by one of his relatives. On being burned in a lamp it gave a good light, though it was somewhat darker-tinted than the ordinary kerosene procurable in the bazaar and gave off more smoke. In the pass from whence the oil was brought there is a stream of water running between two hills, and from small springs in the ground on one side the oil issues and is collected in small holes dug in the ground. The Shiranis use it for outward application to sores on animals, and among them it goes by the name of Water of Shkormá. Attention was drawn to the fact of the existence of this oil during the Viceroy's late visit to the Gualal, and its quality has since been declared by an expert to be very good. As regards the practicability of working the oil on any large scale nothing can be said until a further examination of the locality has been made."—*Ibid.*

#### THE USE OF KEROSENE OIL IN INDIA.

A striking illustration of the increasing use of kerosene oil as an illuminant among the natives is to be found in the returns of the rail-borne trade of Bengal for the last quarter of last year. It is there shown, says the *Pioneer Mail*, that whereas in December 1887 only 46,000 maunds of the oil were transported from Calcutta up-country by rail, in the corresponding month last year the amount was no less than 131,000 maunds. The chief obstacle in the way of the extended consumption of the oil has hitherto been the difficulty of carriage, as it is an article which cannot be easily conveyed without loss over rough roads and paths into country districts; but the figures given show that these obstacles are being gradually surmounted. Patna has become a great centre of distribution, principally by means of country boats, and similar centres will in time be established elsewhere.—*Ibid.*

#### A NEW COCOA-NUT PRODUCT.

The *Ceylon Observer* for the 10th April, quoting from the *Ceylon Advertiser*, says:—

Paragraphs have been going the round concerning a new manufactured product of the cocoa-nut, so much the

reverse of correct, and so calculated to leave a wrong impression as to the future development of the new industry, that it may be well to correct these errors.

The product to which we refer is what has been termed "cocoa nut butter," a name which is incorrect, and is probably accountable for much of the ill-repute into which it has fallen. Being regarded as a "butter," and produced at about half the market price of ordinary butter, those who have written on the subject raise a cry condemning it as a new adulterant of the dairy produce, and a rival of margarine. In the first place, it is not a butter in any sense of the word, and is not at all likely to be employed as an adulterant by reason of its peculiar flavour and colour. It is, in fact, a vegetable lard, and as such it is intended to be used, and is so employed in German kitchens in all cooking processes.

We think it necessary to remove the wrong impression created by allusion to this new article as an "adulterant," because we believe it will build up a future trade in the eastern and western worlds. The natives of India use a large quantity of fat, under the name of "ghee," answering in colour and quality to our "lard." It is the product of buffalo milk, and, inasmuch as Hindoos will not use any animal fat and the Mahomedans avoid the use of hog's lard, this ghee is the only article in use throughout India for culinary purposes, and being in such large demand it is

by no means cheap when purchased in the bazaars. Now, in the newly introduced cocoa-nut fat, misnamed butter, there is at once a better and a cheaper article for Hindoo and Mussulman use. Being a purely vegetable product, it is commended to the scrupulous Hindoo and the prejudiced Mahomedan, and cannot fail to come into extensive use throughout India. If it can be produced by German chemists at Mannheim at half the cost of butter, after incurring the charges on importing the bulky raw material from the East, how much more can it be manufactured in localities where the cocoa-nut is produced.—*Ibid.*

#### MINERAL WEALTH OF AUSTRALASIA.

The following table gives, in a succinct form, the total value of the principal minerals raised in Australasia from their first discovery to the end of 1888, and it will present to the reader a fair idea of the mineral wealth of these colonies. With the exception of coal the development of other minerals in Australia was the outcome of the discovery of gold. The figures given below would, therefore, practically represent the mineral production of Australasia from 1852 to 1888 inclusive, if the value of the coal extracted up to the end of the year 1851 is deducted:—

Colony.	Gold.	Silver and Silver Ore.	Copper.	Tin.	Coal.	Shale.	Total.
	£	£	£	£	£	£	£
New South Wales .....	37,189,817	2,948,754	5,438,262	8,510,372	21,154,307	1,156,782	76,389,294
Victoria .....	222,543,836	87,618	191,022	665,710	25,278	..	223,543,464
Queensland .....	21,319,747	358,572	1,655,894	5,438,509	903,941	..	22,967,083
South Australia .....	891,612	2,800	19,186,163	1,057	..	..	20,081,632
Western Australia .....	219,492	320,381	544,695	..	..	..	1,054,478
Tasmania .....	2,031,520	800	..	4,366,483	179,659	..	6,578,455
New Zealand .....	44,843,642	124,792	17,862	..	2,698,480	..	47,653,776
Australasia .....	329,021,666	3,843,717	27,093,718	18,682,541	24,936,736	1,156,782	444,639,180

It is difficult to obtain much information with regard to other minerals raised in most of the colonies, but if to the total just given be added some 405,167*l.* worth of sundry minerals produced in New South Wales, and 4,857,866*l.*, nearly the whole of which represents the total value of Kauri gum extracted in New Zealand up to the end of 1888, the grand total will be raised to 409,902,213*l.* Deducting therefrom the sum of 279,923*l.*, which represents the value of coal raised in New South Wales prior to the year 1852, the difference, 409,622,290*l.*, practically shows the total value of the mineral wealth produced by the Australasian colonies from 1852 to 1888 inclusive; and during a period of 37 years the average yearly production amounted to 11,070,873*l.*

In the year 1888 the total value of minerals raised in each colony and in Australasia was as follows:—New South Wales, 3,856,187*l.*; Victoria, 2,503,925*l.*; Queensland, 2,066,979*l.*; South Australia, 369,014*l.*; Western Australia, 206,847*l.*; Tasmania, 520,878*l.*; and New Zealand, 1,531,614*l.* Total for Australasia, 11,055,444*l.*—*Ibid.*

Articles of interest on "The Cultivation of Cochineal in the Canaries" and on "Compressed or Tablet Tea" will be found on pages 90 and 96 respectively of the *Board of Trade Journal* for July.

#### THE NEW FERTILISER LAW.

The following Act relating to the fertiliser trade in the State of New York passed the Legislature of this State at its recent session, and in order to give information to all interested in the business, the New York Fertiliser and Chemical Exchange decided to publish a copy of the Bill for gratuitous circulation.

SECT. 1. All commercial fertilisers which shall be offered for sale to be used in this State shall be accompanied by an analysis stating the percentages contained therein of nitrogen or its equivalent of ammonia, of soluble and available phosphoric acid, the available phosphoric acid either to be soluble in water or in a neutral solution of citrate of ammonia as determined by the methods agreed upon by the American Society of Agricultural Chemists, and of potash soluble in distilled water. A legible statement of the analysis of the goods shall be printed on or attached to each package of fertilisers offered for sale for use in this State; and where fertilisers are sold in bulk to be used in this State, an analysis shall accompany the same, with an affidavit that it is a true representation of the contents of the article or articles.

SECT. 2. Manufacturers residing in this State and agents or sellers of fertilisers made by persons residing outside the limits of this State shall, between the 1st and 20th days of July in each year, furnish to the Director of the New York State agricultural experiment station at Geneva a list of the commercial fertilisers they manufacture or offer for sale for use in this State, with the names or brands by which they are known on the market, and the several percentages of nitrogen or its equivalent of ammonia, of phosphoric acid soluble and available, and of potash, either single or combined, contained in said fertiliser, as called for in section 1 of this Act. Whenever any fertiliser or fertilising ingredients are shipped or sold in bulk for use by farmers in this State, a statement must be sent to the Director of the New York State agricultural experiment station at Geneva, giving the name of the goods so shipped, and accompanied with an affidavit from the seller, giving the analysis of such percentage guaranteed.

SECT. 3. Whenever a correct chemical analysis of any fertiliser offered for sale in this State shall show a deficiency of not more than one-third of 1 per cent. of nitrogen or its equivalent of phosphoric acid, or one-half of 1 per cent. of ammonia soluble or available, and one-half of 1 per cent. of potash soluble in distilled water, such statements shall not be deemed false within the meaning of this Act. This Act shall apply to all articles of fertilisers offered or exposed for sale for use in the State of New York, the selling price of which is 10 dols. per ton or higher, and of which they are part or parcel, and of any element into which they enter as fertilising material, among which may be enumerated nitrate of soda, sulphate of ammonia, dissolved bone black and bone black undissolved, any phosphate rock, treated or untreated with sulphuric or other acids, ashes from whatever source obtained, potash salts of all kinds, fish scrap, dried or undried, also all combinations of phosphoric acid, nitrogen, or potash, from whatever source obtained, as well as all and every article that is or may be combined for fertilising purposes.

SECT. 4. All manufacturers or dealers exposing or offering for sale in this State fertilisers containing roasted leather or any other form of inert nitrogenous matter, shall, in legible print, state the fact on the packages in which the fertilisers are offered or exposed for sale.

SECT. 5. Every person, firm, or corporation violating any of the provisions of this Act shall, upon conviction thereof, for the first offence be punished by a fine not less than 50 dols. and not more than 200 dols., and for the second offence by double the amount in the discretion of the court, such fines to be paid to the officer whose duty it is to enforce the provisions of this Act, to be used by him for that purpose, and to be accounted for to the Comptroller.

SECT. 6. The Director of the New York State agricultural experiment station at Geneva is charged with the enforcement of the provisions of this Act, and shall prosecute in the name of the people, for violations thereof; and for that purpose he may employ agents, counsel, chemists, and experts, and the court of special sessions shall have concurrent jurisdiction to hear and determine charges for violating the provisions of this Act committed in their respective counties, subject to the power of removal provided in chapter 1 of title 6, of the code of criminal procedure.

SECT. 7. And the said Director of the New York State agricultural experiment station at Geneva, or his duly authorised agents shall have full access, egress and ingress to all places of business, factories, buildings, cars, vessels, or other places where any manufactured fertiliser is sold, offered for sale, or manufactured. Such Director shall also have power to open any package, barrel, or other thing containing manufactured fertiliser, and may take therefrom sufficient samples; and whenever any such fertiliser is so taken for samples, it may be divided into different portions, and one or more portions sealed in such a way that it cannot be opened without upon examination giving evidence of having been opened to the person sealing the same, and delivered to the person from whom said sample is taken, or any other person that may be agreed upon by the said Director or his agents who takes the same, and the person from whom it is taken, which portion so delivered may, upon consent of the parties, be delivered to a chemist for the purpose of being analysed other than the chemist employed by said Director.

SECT. 8. The sum of 20,000 dols., or so much thereof as may be necessary, is hereby appropriated out of any money in the Treasury not otherwise appropriated, to be used by said Director of the New York State agricultural experiment station at Geneva, as shall be authorised by the board of control thereof, in enforcing the provision of this Act. Said sum shall be paid to said Director by the Treasurer upon the warrant of the Comptroller, upon vouchers to be approved by the Comptroller, in such sums and at such times as said Director may require, who shall file a statement for what purposes he desire the same.

SECT. 9. Agents, representatives, or sellers of manufactured fertiliser, or fertilising material made or owned by parties

outside of this State, and offered for sale for use in this State, shall conform to the provisions of this Act, and shall be subject to its penalties, and in all particulars shall take the place of their non-resident principal.

SECT. 10. Chapter 222 of the laws of 1878 is hereby repealed.

SECT. 11. This Act shall take effect immediately.—*Chem. Trade Journ. from Oil Paint and Drug Reporter.*

#### THE GERMAN DRUG TRADE.

The German commercial statistics for 1889 have just been published, and show the value of all imports into the country to have been 4,087 millions of marks, that of the exports being 3,256 millions. Compared with the previous year, these figures show that the imports have increased by 6.51 million marks, or nearly 16 per cent., while the exports have diminished by 3 per cent. (96 million marks). Drugs and chemicals show a very marked increase, both in imports and exports, on the preceding year, the following being the values, in thousands of marks:—

	Imports.		Exports.	
	1889.	1888.	1889.	1888.
Raw materials for chemical industry	74,819	65,241	8,356	7,707
Drugs for medicine and perfumery..	17,946	15,594	6,845	5,760
Raw dyestuffs .....	13,998	13,299	5,439	5,111
Simple chemicals, bases, acids, and salts.....	25,805	27,715	63,569	60,328
Ether, essential oils, medicaments, and perfumeries .....	10,385	9,913	20,737	27,241
Paints, varnishes, lacquers, and glues	10,875	9,717	9,632	9,505
Pitch, tar, and tar distillates .....	19,152	16,713	10,487	8,910

The largest increase in value among the imports is shown by coal-tar oils, carbolic and picric acids, carbonate of ammonia, camphor and dyewood extracts, and under exports by soda and potash salts, albumen, carbolic acid. The principal decreases are, in exports—cinchona salts and quinine preparations, glycerin, iodides, salicylates, tartar materials, aniline dyes, and other coal-tar dyes; in the imports—bichromates of soda and potash, gums, cinchona, indigo, iodine, and phosphorus. Camphor was imported to the extent of 1,414,000 marks, while the exports were 921,000 marks. The values of the exports of some of the principal medicinal preparations shipped from Germany last year were:—

	Marks.
Salicylates.....	2,613,000
Iodine.....	315,000
Iodides.....	2,367,000
Alcoholic tinctures .....	624,000
Essential oils.....	1,050,000
Cinchona salts and preparations.....	6,864,000
Alkaloids and their salts.....	3,720,000
Toilet soaps .....	2,030,000

—*Chemist and Druggist.*

#### EXPLOSION IN A PICRIC ACID WORKS.

About midday on June 27th a terrific explosion wrecked the greater part of the works of the Chemische Fabrik Rhein in Germany. The cause of the disaster was a fire, which had originated in the drying-rooms of the picric-acid

department, and exploded part of the stock of that material. The picric-acid department itself is completely destroyed, but a store of 60 tons of picric acid kept at another part of the works was saved. No lives were lost, and the acid manufacture will be taken up again as soon as possible in another part of the factory.—*Ibid.*

#### "BENZOL" MANUFACTURE IN BAKU.

The Rothschilds are building works in Baku (Russia) for the manufacture of benzol from naphtha residue. The experiments have shown that there is every probability that this industry will be successful. Schibajew's oilworks in Baku have been manufacturing both benzene and anthracene for many years.—*Ibid.*

#### THE ALKALI TRADE.

The efforts which are being made to syndicate the Leblanc alkali works in England, and the probability of the union including, within a short time, the ammonia soda works, have raised hopes in Germany of increasing the export trade. A considerably enhanced cost of British alkali will not only help German competition in foreign neutral markets, but will also stimulate the trade with Great Britain. The quantity of soda now annually shipped to England amounts to about 16,000 cwt., that of potash being about 28,000 cwt. These are not large quantities; but a small addition to the cost of English-made alkali would enable the German manufacturers to increase their exports very greatly.—*Industries.*

#### MINERAL PRODUCE OF THE UNITED KINGDOM.

Description of Mineral Raised.	1888.		1889.	
	Quantity.	Value at Mines.	Quantity.	Value at Mines.

## COPPER.

We have again to report an enormous delivery to consumers out of stores. The total so stated is 18,781 tons, making, with the 17,030 tons in May, a delivery not only unexampled in the trade, but nearly 9,000 tons in excess of any two previous consecutive months. Time must show whether any portion of this is due to consumers stocking in their own warehouses in anticipation of their future requirements, or whether it is a purely natural flow of business.

Meantime it has reduced the stocks of copper in warehouse in this country to 38,521 tons, a quantity so small that traders here are justified, and, in fact, bound to exercise unusual caution in all their dealings for forward delivery. The market has had an upward tendency with a large daily turnover on change. The highest figure for G. M. B. being 59*l.* 10*s.*, and the lowest 57*l.* closing firm at 58*l.* 2*s.* 6*d.*

## CERTIFICATES OF ORIGIN IN FOREIGN COUNTRIES.

The following summary of replies received from Her Majesty's Representatives in the principal commercial countries respecting Customs requirements in the matter of certificates of origin has been received at the Board of Trade from the Foreign Office:—

*Belgium.*—Only required in exceptional cases, such as for animals imported from infected countries, vines, &c.

*Brazil.*—None required.

*Bulgaria.*—Certificates required; those issued by Chambers of Commerce will be accepted, and they should be in the French language.

*Denmark.*—None required.

*Ecuador.*—None required.

*France.*—Required for some articles, such as live plants and meat. Certificates issued by Chambers of Commerce would not be accepted.

*Germany.*—Only required for pork (including bacon and sausages).

*Mexico.*—None required.

*Netherlands.*—Only required for articles the importation of which is prohibited, but which may be admitted by exception on certain conditions.

*Norway and Sweden.*—None required.

*Portugal.*—None required.

*Romania.*—Certificates required; those issued by Chambers of Commerce in their corporate capacity will be accepted.

*Russia.*—None required.

*Serbia.*—Certificates required; those issued by a Chamber of Commerce at the port of despatch will be accepted. They must be attested on arrival at Belgrade by the British consular or diplomatic representative.

*Spain.*—Certificates required; they are to be signed before mayors, Chambers of Commerce, police authorities, or public notaries, and must be visé before the Spanish Consul.

*Switzerland.*—None required.

*United States of America.*—None required.

*Uruguay.*—None required.

—Board of Trade Journal.

## THE CONDITION OF GERMAN CHEMICAL INDUSTRY SINCE 1881.

From the Report to the Bureau des Deutschen Handelstages by Consul Annacke. Chem. Ind. **13**, 159—162.

*Hydrochloric acid* and *bleaching powder* have both been the subjects of a great deal of fluctuation since 1881. The high price of bleach in England, maintained by the Bleach Association, had a favourable effect on the German market, the Leblanc soda manufacturers being enabled in some measure to recoup themselves for the losses incurred on their alkali. In 1881 the demand for salts exceeded the supply, the price in consequence rising 10 per cent. Further advances were effected in 1886 and 1887, hydrochloric acid thus attaining a price hitherto unprecedented, certain qualities in particular, notably that free from iron, being sold at specially good rates. Bleach towards the beginning of this period was in great request, the more so as an outbreak of cholera occurred in South France. Later, the manufacturers, by utilising to a fuller extent their existing works and erecting fresh plant, were able to supply in full the home demand, the deficiency of about 50,000 double-ctr. being previously imported. (The editor of Chem. Ind. adds that Germany will shortly export bleaching materials, as bleaching powder is being made from the Stassfurt magnesium chloride; and chloride of lime, made electrolytically from potassium chloride, is already in the market.)

The manufacture of *chlorate of potash* has long been unprofitable in Germany, as the production of hydrochloric acid is only sufficient for use as such and for manufacturing bleach, whilst in England there is an excessive over-production. Last year the English make chiefly was imported.

Towards the end of 1883 a syndicate of Stassfurt firms was formed for the sale of *potash salts* through one channel. Good business was done for some time, but in 1888 the price had fallen so much that scarcely 100 M. per 100 kilos. could be realised.

The manufacturers of *oxalic acid* and *salts of sorrel* were in a prosperous position at the beginning of the last decade. Then came a period of adversity. America, in consequence of bad trade, reduced its import, the result being that the English output, previously relieved by export to America, was thrown on the European market. This exportation to Germany annually increased although prices continued to fall. In 1888, however, a convention was arranged between the English and German manufacturers of the acid, and fairer prices were obtained. The existence of the convention has been prolonged owing to the English manufacturers recognising the fact that their German competitors can produce this article at a lower cost. (The Editor of Chem. Ind. contradicts the last statement, adding, that several German firms have latterly been compelled to discontinue the manufacture.)

Great changes have taken place since 1884 in the *tartar* trade. Formerly this article was imported into Germany from France, Italy, and Austria. Since 1884, however, the supply from France has entirely ceased, and that from the other two countries has greatly diminished. The Austrian tartar would have been replaced by the superior quality received through London from the Cape, if the American market had not forced up the price of the same. As it was, the Italian manufacturers, being excluded from France by the increased import duty on Italian tartar, sought a market in Germany, and by underselling their Austrian rivals were enabled to obtain a monopoly of the trade.

The condition of the *tartaric acid* trade has not been satisfactory. Germany buys the raw material for the manufacture of the acid from abroad, and exports 90 per cent. of its manufacture, so that the increased foreign duties and larger production in England led to a glut in the market. To remedy this state of things a convention was formed in 1884 and a diminished output resolved upon. Two years later English speculators bought up the German stocks and raised the price, an over-production on the part of the manufacturers again ensuing, which greatly injured the trade of the following year. After 1888, prices were reduced, the English price falling 10—20 per cent., and the Austrians selling in Germany at 10—15 per cent. less than in their own country.

The consumption of *acetic acid* constantly increases, larger quantities being employed both in the textile industries and for vinegar manufacturing. Unfortunately the German export trade is hampered with duties imposed by Italy and Russia.

The quality of *citric acid* made in Germany is so excellent that almost the whole consumption is supplied by this country.

*Borax*, formerly a product of chiefly English manufacture, is now largely sold by the Hamburg factories.

In 1881—83 the enormous quantities of double distilled *glycerin*, consumed by the American dynamite manufacturers, led to an increase of 100 per cent. in the price. In 1884, however, the price had re-assumed its normal level, and, although an American syndicate bought one million kilos., the market remained unaffected. The American manufacturers in 1886 began to buy crude glycerin, and the price speedily rose 140 per cent., but fell again two years later, and only partially recovered in the following year.

The *charcoal-manufacturing* and *wood-distillation* industries have not been in the flourishing condition that the natural advantages in the shape of abundant forests, cheap transport and fuel, and low rates of wages, should warrant. The export trade has decreased in consequence of the higher duties levied abroad.

*Wood-tar* has fallen considerably in price since 1884 through the importation of the same from Russia and Austria.

The stocks of *coal-tar* continued to increase until 1888, but began to diminish again towards 1889, and the price at the present time is more profitable.

Better business has been done in *wood-pitch*. Although the exportation to Austria has been cut off, the home market has not been affected thereby, and the price has even slightly advanced.—E. B.

## Monthly Patent List.

\*The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

9285. G. Stevenson. Improvements in apparatus for automatically measuring defined quantities of solid or liquid substances. June 16.

9312. G. Horner. Improvements in surface condensers. Complete Specification. June 16.

9326. J. O. Woods. Improvements in vaporisers. Complete Specification. June 17.

9354. C. H. Huntley. Improvements in recovering saline and other substances from solution. June 17.

9379. W. B. Bull. Improvements in means for purifying liquids for the prevention of steam boiler incrustation, ageing liquors, &c. Complete Specification. June 17.

9416. A. Anderson and J. Wilson. Apparatus for burning liquid fuel. June 18.

9518. J. Foster. Improvements in and relating to apparatus for evaporating solutions containing salts and for other liquids. June 19.

9554. L. H. A. W. Sack. Apparatus for automatically drawing off viscous substances. Complete Specification. June 20.

9604. W. E. Smith. Improvements relating to apparatus for burning liquid fuel. June 20.

9685. G. Cox. Improvements in the manufacture of tin, iron, and other metal drums for carrying oils and other liquids. June 23.

9703. E. F. Edgar. An improved furnace. June 23.

9941. R. Haddan.—From E. Passburg, Germany. An improved method and apparatus for drying aqueous matter. Complete Specification. June 26.

10,116. F. B. Pemberton. An improved composition for preventing or obstructing the passage of heat through bodies, and for the deadening of sounds, and methods of applying the same. June 20.

10,133. P. Abrahamson. Certain improvements in oven and other heating and fire-chamber doors. Complete Specification. July 1.

10,172. H. von Bayer. Improvements in and relating to a method of and apparatus for producing cold, and for freezing liquid and other substances. Complete Specification. July 1.

10,374. J. Gamgee. Improvements in condensing or liquefying vapours or gases, and in apparatus therefor. Filed July 4. Date applied for December 9, 1889, being date of application in Belgium.

10,380. J. Murrie. Improvements in and relating to pyrometers or thermometers. July 4.

10,398. L. P. Cohen and E. Hermann. Improvements in furnaces. Complete Specification. July 5.

10,524. T. Gaunt and E. H. Clapp. Improvements in evaporating apparatus. Complete Specification. July 8.

10,539. E. Holt. Improvements in automatic apparatus for regulating the supply of air to furnaces. July 8.

10,592. M. Honigsmann. Improvements in heating gaseous, liquid, and solid substances. July 8.

10,679. E. Fahrig. A press for impregnating liquids with gases. July 9.

10,721. W. L. Wise.—From Solvay and Co., Belgium. Improved method of, and means for charging materials into apparatus, such as cupolas, blast furnaces, lime kilns, scrubbers, and absorption towers. July 10.

10,724. W. A. Carlyle. An improved compound for manufacturing crucibles or the like vessels or utensils. July 10.

10,788. H. M. Saint Denis. Improvements in centrifugal drying machines or hydro-extractors. July 11.

10,856. A. Silverberg and C. Detering. Improvements in carbonising apparatus. Complete Specification. July 12.

10,888. J. H. R. Diasmore. Improvements in or connected with apparatus for drying granular substances. July 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1889.

11,925. C. A. Bempen and E. Andre. Valves for regulating the pressure of gas and other fluids. June 25.

12,885. M. Miller. Steam or air superheater. July 16.

13,814. W. Young. Apparatus for evaporating brine, &c., under a vacuum. July 9.

13,816. W. Young. Apparatus for boiling brine, &c., in a vacuum. July 2.

14,416. P. Radcliffe. Furnaces for melting, &c. July 2.

1890.

6864. J. J. Shedlock and J. J. Meldrum. See Class X.

8568. W. P. Thompson.—From J. A. Bowden. Filters. July 16.

8915. O. Guttman. See Class VII.

### II.—FUEL, GAS, AND LIGHT.

#### APPLICATIONS.

9320. T. Travers. Improvements in gas burners, and apparatus for naphthalising gas. June 16.

9331. J. A. Whitby. The magic firelighter. June 17.

9394. J. C. Chandler. Improvements in charging gas retorts, and apparatus therefor. June 17.

9521. J. C. Mewburn.—From O. W. Ketchum, Canada. Improvements in and connected with gas producers, or apparatus for producing gas to be used as fuel. June 19.

9529. C. Herzog. An improved gas generator to be independent of climatic variations. June 19.

9540. C. Herzog. An improved method of and means for the regulation of the quality of an artificial gas. June 19.

9642. G. Horsley and A. C. Wilson. Improvements in or relating to the manufacture of coke. June 21.

9651. W. Loé and C. Gumbart. Improvements in or relating to the treatment of peat for the production of fuel and by-products. June 21.

9733. S. Pitt.—From E. J. Jerzmanowski, United States. Improvements in the manufacture of illuminating gas. Complete Specification. June 23.

9786. L. Hendle and E. Schuberth. An improvement on electric incandescent lighting, called "The non-consuming glow light filament." June 24.

9956. R. Kennedy. Improvements in heating by electricity. June 27.

10,155. J. Ruseoe. Improvements in means or appliances for facilitating the operations of charging and drawing the charges of certain gas retorts. July 1.

10,329. J. Love. Improvements in and relating to apparatus for the manufacture of gas for illuminating and other purposes. July 3.

10,713. W. Hughy. An improved portable apparatus for charging inclined gas retorts. July 10.

10,831. L. Van Vestrant. Improvements in means and apparatus for charging inclined gas retorts. July 12.

10,869. G. F. Priestly. Automatic machinery for charging and discharging gas retorts. July 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

10,660. W. P. Thompson.—From J. Wilson and A. Mason. Appliances for burning hydrocarbons. July 2.

10,661. W. P. Thompson.—From J. Wilson and A. Mason. Process for burning petroleum and other hydrocarbons, and apparatus therefor. July 2.

11,459. J. Dheyne, Comte de Nydprick, and F. de la Hault. Apparatus for generating gas or vapour from combustible liquids. July 9.

11,855. J. Morris. Artificial fuel. July 2.

12,043. J. F. L. Monier. Manufacture of gas from atmospheric air. July 2.

12,655. J. Watson. Heating apparatus. July 16.

13,653. W. P. Thompson.—From P. Marix and M. Notkin. Process for purification of mineral oils, and production of alcohol. July 2.

13,933. R. B. Helliwell. Firelighters. July 9.

14,715. E. Mansfield. Oil-gas apparatus. July 2.

14,717. G. W. Macalpine. Coke-oven valves. July 9.

19,256. G. C. Trewby. Method and means for charging gas retorts. July 2.

1890.

260. J. Stears. Preventing deposit of carbonaceous matter in gas ascension pipes. July 9.

1556. W. C. Owston. Coal saving composition. July 9.

6800. W. C. Andrews. Purification of illuminating or heating gases. July 9.

6804. W. C. Andrews. Apparatus for purification of illuminating gas. July 9.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

#### COMPLETE SPECIFICATION ACCEPTED.

1889.

19,183. J. A. Yeadon and W. Adgie. Retorts or furnaces for the distillation of coal, or other analogous purposes. June 25.

### IV.—COLOURING MATTERS AND DYES.

#### APPLICATIONS.

9322. R. Holliday and Sons, Lim., and T. Holliday. Improvements in the formation of new colouring matters in or upon cotton or other fibre. June 17.

9530. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Improvements in the production of blue-green colouring matters. June 19.

9537. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. Improvements in and relating to the manufacture of substantive dyestuffs, and of new materials therefor. June 19.

9676. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. Improvements in and relating to the manufacture of substantive dyestuffs, and of materials therefor. June 21.

9768. J. Dawson and R. Hirsch. The production of a new  $\alpha$ - $\beta$ -naphthylendiammonosulpho acid. June 24.

9825. A. J. Boulton.—From G. Boulet, fils, Donard, and Contamine, France. See Class XII.

9923. O. Imray.—From C. F. Boehringer, Sohn, Germany. Manufacture of dehydromethylphenyl-pyrazine. June 26.

10,047. O. Imray.—From The Society of Chemical Industry, Switzerland. Improvements in the production of colouring matters. June 28.

10,095. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. Improvements in the manufacture of trioxy-benzo-phenone, a colouring matter of the oxyketone group. June 30.

10,101. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Improvements in the production of azo-colouring matters. June 30.

10,237. R. Holliday and Sons, Lim., and P. R. E. Deidler. Improvements in the manufacture of mono-sulpho acid of alpha naphthol. July 2.

10,240. R. Holliday and Sons, Lim., and P. R. E. Deidler. Improvements in the manufacture of azo colours. July 2.

10,401. W. S. Conrad. An instantaneous copying ink. July 5.

10,448. Brooke, Simpson, and Spiller, Lim., and A. G. Green. The production of new azo-colouring matters. July 5.

10,470. J. Dawson and R. Hirsch. Process for the manufacture of new basic blue colouring matters. July 7.

10,509. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of artificial indigo, and of a new material suitable for use therein. July 7.

10,599. H. H. Lake.—From K. Oehler, Germany. Improvements relating to the manufacture of colouring matters. July 8.

10,802. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Production of novel colouring matters for wool dyeing and printing. July 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

13,558. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Production of a new colouring matter suitable for dyeing and printing cotton without the aid of a mordant. June 25.

13,710. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Production of azo-colouring matters from dioxynaphthalinmonosulphonates. June 25.

14,222. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Production of diazo colouring matters. July 16.

14,388. R. Ashton. Method of preparing colours for making writing inks. July 16.

15,706. M. Lange. Production of thioxydiphenylamine. July 2.

### V.—TEXTILES, COTTON, WOOL, SILK, Etc.

#### APPLICATIONS.

9430. T. Mellor. Improvements in the method of and apparatus for steaming, boiling, and disinfecting fabrics or fibres. June 18.

9643. A. Hodge. Improvements in the treatment of ramie or rena fibre, or China grass and such like fibrous growths, and in the appliances or mechanism connected therewith. June 21.

9711. J. Miller, sen., and J. Miller, jun. Improvements in the method of and apparatus for rendering textile fabrics waterproof by one treatment or process. June 23.

10,285. T. J. Hutchinson. Improvements in the method of and means for removing grease and fatty matters from textile fabrics. July 3.

10,517. E. Dezwarte and The General Financial and Industrial Corporation, Limited. Improvements in the treatment of ramie, hemp, flax, and other fibrous plants. July 7.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

13,626. A. S., and F. Ambler. Cleansing wool and like animal fibres and apparatus therefor. July 2.

15,333. K. T. Sutherland and G. Esdaile. Treatment of fibres to promote easier cleansing or bleaching. July 9.

18,932. K. T. Sutherland and G. Esdaile. Method of treating vegetable fibres to produce easy spinning and greater strength. July 16.

1890.

7389. J. Longmore and W. L. Watson. Decorticating rheia, jute, and other vegetable fibrous stems. July 16.

8520. P. A. Fayler. Machines for decorticating ramie or other textile plants in a dry or a green state. July 9.

#### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

##### APPLICATIONS.

9322. R. Holliday and Sons, and T. Holliday. See Class IV.

10,323. W. Hutchinson. Improvements in apparatus for boiling, scouring, or cleansing textile fabrics. July 3.

10,324. W. Hutchinson. Improvements in apparatus for use in the treatment of cloth with bleaching and other liquors. July 3.

10,396. F. A. Blair. Improvements in and connected with vats or apparatus and machinery for washing, bleaching, scouring, mordanting, and drying yarns or stubbing in the bank. July 5.

#### COMPLETE SPECIFICATION ACCEPTED.

1890.

5051. C. Kellner. See Class XI.

#### VII.—ACIDS, ALKALIS, AND SALTS.

##### APPLICATIONS.

9670. J. C. Steele. Improvements in the packing or putting up of chloride of lime and other substances. Complete Specification. June 21.

9793. F. W. A. Frerichs. Improvements in and relating to the manufacture of carbonates of alkalis and acetone. Complete Specification. June 24.

9929. A. G. Haddock and J. Leith. Improvements in the manufacture of alkaline carbonates and by-products, and in arrangement of plant therefor. June 26.

9997. F. Ellershausen. Improvements in the manufacture of sodium ferride and caustic soda. June 27.

10,115. H. Precht. Improvements in the process of and apparatus for purifying double carbonate of potassium and magnesium. June 30.

10,194. O. Murray.—From J. Storer, Australia. A process for producing alkaline carbonates from sulphates. July 1.

10,399. J. Barlow and H. T. Everist. Improvements and apparatus in connexion therewith for the crystallisation of salt from brine. July 5.

10,451. C. G. Moor. See Class XVIII., B.

10,737. A. P. J. Archbold. Improvements in the manufacture of salt for domestic purposes. July 10.

10,790. H. J. Haddan.—From C. Negrier, France. Improvements in apparatus for the concentration of sulphuric acid. July 11.

10,906. F. Ellershausen. Improvements in the manufacture of caustic soda. July 12.

10,910. F. Ellershausen. Improvements in the manufacture of sulphide of sodium. July 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

11,975. E. Augé. Manufacture of soda ash. July 2.

13,575. M. N. D'Audria. Treating liquid acid residues containing iron to obtain products therefrom. July 2.

13,726. E. de Cuyper. Recovering valuable substances from the mother-liquor of copper ores. July 16.

16,609. W. Wolters. Recovery or regeneration of nitric acid employed in the manufacture of chlorine. July 9.

1890.

8090. J. D. Pennoek and J. A. Bradburn. Manufacturing bleaching powder and caustic soda. July 2.

8915. O. Guttmann. Apparatus for condensation of nitric acid and other distillation products. July 16.

#### VIII.—GLASS, POTTERY, AND EARTHENWARE.

##### APPLICATIONS.

9867. W. H. Hilde. Improvements in the manufacture of hollow glass ware, and in apparatus therefor. June 25.

9942. O. Dillmann. An improved method for producing coloured designs on glass. June 26.

10,018. D. Rylands. Improvements in the appliances, processes, and heat producers used for annealing or toughening bottles or other ware. June 28.

10,795. A. Bevington. An improved process for the decoration of china and earthenware. July 11.

10,847. D. Rylands and R. Morant. Improvements in the manufacture of glass tubing. July 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

13,036. A. Taylor. Method and apparatus for building up inside of kilns for burning enamelled bricks and tiles. July 16.

13,994. S. Washington. Finishing glass ware, and apparatus therefor. July 2.

14,156. The Coalport China Co. (J. Rose and Co.) and T. J. Bott. Ornamenting china, earthenware, glass, &c. July 16.

1890.

1820. H. Gurney. Method and apparatus for burning bricks and tiles. July 2.

6058. G. Scott. Method and apparatus for manufacturing roofing plates from glass, &c. July 2.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

### APPLICATIONS.

9306. C. J. Howe. An instrument for testing the setting properties of cements and plasters. June 16.

9381. D. H. Close. Improvements in the manufacture of bricks. June 17.

9618. J. C. Bloomfield. Enamelled bricks, blocks, slabs, or tiles. June 21.

10,002. T. Breakell and J. W. Breakell. A method of colouring and polishing calcareous and other stones, and producing variegated effects thereon in one or more colours. Complete Specification. June 28.

10,036. J. P. Bayly. — From W. Lenderoth, Canada. Improvements in and relating to the manufacture of porous earthenware building material. June 28.

10,427. W. Darling. Improvements in and relating to the calcining of carbonaceous minerals for cements and other purposes. July 5.

10,548. L. Wilson. Improvements in blocks and tiles for paving, flooring, facing walls and ceilings, and for similar purposes. July 8.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

13,008. J. Wilson. Construction of fire-resisting flooring, decking, &c. July 9.

13,749. H. Aitken. Treating timber. July 9.

1890.

3184. A. Rovedins. Improvements in and connected with paving. July 9.

6058. G. Scott. See Class VIII.

## X.—METALLURGY, MINING, Etc.

### APPLICATIONS.

9684. C. T. J. Vautin. Improvements in the recovery of gold from solutions. June 21.

9746. A. Jones and J. W. Sheel. Safety appliance for Bessemer converters. June 24.

9830. D. Rennie. Improvements in furnaces for melting crucible steel and other metals. June 25.

9835. R. T. Cooke. Improvements in ingot heating furnaces. June 25.

9900. A. Philip. Improvements in the manufacture of sodium and potassium. June 26.

9906. C. A. Burghardt. An improvement in the manufacture of tin andterne plates. June 26.

10,029. J. Ward. Improvements in and relating to the manufacture of compound armour plates. June 28.

10,062. J. Bradbury. A new or improved process for the utilisation of oxide of iron obtained as a by-product in the smelting and extraction of copper from pyrites, or from spent oxide produced in the manufacture of sulphuric acid. June 30.

10,175. J. B. Torres. Certain new or improved refractory compounds and mixtures. July 1.

10,510. C. G. Cunningham. Improvements in the reduction of ores containing lead, zinc, silver, or gold. July 7.

10,537. C. J. Ellis and A. Dickie. Improvements in re-converting for re-use residuary cyanides such as are obtained in extracting gold from ores. July 8.

10,555. E. Regnander and P. A. Waller. Improvements in moulding ingots of phosphor tin, phosphor bronze, and the like, and in apparatus therefor. July 8.

10,620. W. Withington. Improvements in the manufacture of steel castings. July 9.

10,625. J. E. Stead. Improvements in the manufacture of basic phosphatic slag. July 9.

10,711. G. A. Herdman. Improvements in treating waste products resulting from the smelting of ores, and in producing a valuable product therefrom, or from analogous compounds. July 10.

10,783. A. McDougall. A new process for recovering tin from tin plate in which zinc white is produced as a product. July 11.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

12,556. W. P. Thompson. — From A. A. L. Levy. Coating or plating metal articles. July 16.

14,226. A. J. Boulton. — From M. Castelnaud. Treatment of ores. July 2.

14,357. E. Dodé. Refining and separating precious metals. July 2.

18,985. C. A. Piat. Metallurgical furnaces. July 16.

1890.

1733. J. F. Spence. Apparatus for charging pig iron and scrap metal into open-hearth furnaces. July 9.

4675. R. T. Tiedford. Welding metals. July 2.

6864. J. J. Shedlock and J. J. Meldrum. Apparatus for production and application of gases for metallurgical and other purposes. July 9.

7733. H. H. Lake. — From G. W. Cummins. Process and apparatus for preventing access of air to iron and steel during annealing. June 25.

7820. F. G. Bates. Preparation of materials for converting low steel or iron into high grade steel by the cementation process. June 25.

8655. E. C. Miller. — From The Magnolia Anti-friction Metal Co. Compositions or alloys for anti-friction purposes. July 16.

8989. H. H. Lake. — From G. W. Cummins. Treating copper and its alloys to prevent oxidation and deoxidation during heating and annealing. July 16.

8991. H. H. Lake. — From J. D. Brown. Manufacture and treatment of iron and steel, and compounds therefor. July 16.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### APPLICATIONS.

9330. W. H. Dowland and W. Mills. Improvements in the electrolysis of chlorides, and apparatus therefor. June 17.

9361. T. L. Willson. Improvements in electric reduction of metals, and in apparatus therefor. June 17.

9857. M. W. Dewey. Improvements relating to welding, soldering, brazing, and otherwise working metals by electricity, and to apparatus therefor. Complete Specification. June 25.

9861. A. J. Boulton. — From D. Tommasi and C. Therye, France. Improvements in electrical storage batteries. June 25.

9956. R. Kennedy. See Class II.

9991. T. Parker. Improvements in or connected with the manufacture of iron by electrolysis. June 27.

10,038. A. Watt. Improvements in the electrolytic treatment of metals. June 28.

10,044. Sir C. S. Forbes. Improvements in primary batteries, and in apparatus connected therewith. June 28.

10,123. M. W. Dewey. Improvements relating to welding, soldering, and otherwise working metals by electricity. Complete Specification. Filed June 30, date applied for December 11, 1889, being date of application in United States.

10,125. M. W. Dewey. Improvements in electric heating apparatus. Complete Specification. June 30.

10,181. T. M. Foote. Improvements in secondary batteries. Complete Specification. July 1.

10,211. V. Fabris. Improvements in electric primary batteries. July 2.

10,515. A. J. Jarman. An improved connector for the electrodes and cells of primary and secondary electrical batteries. Complete Specification. July 7.

10,527. E. S. D'Odiardi and A. Thompson. Improvements in magneto-voltaic and static electrodes. July 8.

10,530. E. S. D'Odiardi and A. Thompson. Improvements in liquid electrodes. July 8.

10,538. G. J. Wier. Improvements in galvanic batteries. July 8.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

10,822. G. Button and W. E. Wyeth. Apparatus for extracting gold and silver from their ores by electrical amalgamation. July 9.

11,242. Siemens Bros. and Co., Lim.—From Siemens and Halske, Germany. Dynamo-electric, magneto-electric, and electro-dynamic machines. July 16.

12,772. A. de Castro. Means or apparatus for generation and conversion of electric energy. July 16.

1890.

1347. T. Coad. Fluid for primary batteries. June 25.

4191. T. D. Farrall. Method and mechanism for generating heat, steam, and light by electricity. July 9.

4949. L. Weigert. Electrolytic solution for galvanic batteries. July 9.

5054. C. Kellner. Bleaching fibrous material by aid of electricity. July 9.

5420. C. Kellner. Process and means for manufacture of cellulose by aid of the electric current. July 16.

6177. G. Barker.—From H. Woodward. Secondary batteries. July 16.

6236. A. J. Jarman. Improved storage battery. June 25.

7185. W. P. Thompson.—From C. L. Coffin. Method and apparatus for welding metals electrically. July 2.

7853. W. P. Thompson.—From C. L. Coffin. Method and apparatus for welding metals electrically. July 9.

7876. H. H. Lake.—From E. A. Colby. Methods and apparatus for melting, refining, and casting metals, &c., by electricity. July 16.

8703. W. P. Thompson.—From C. L. Coffin. Electric welding. July 9.

#### XII.—FATS, OILS, AND SOAP MANUFACTURE.

##### APPLICATIONS.

9614. P. A. Newton.—From The Chesebrough Manufacturing Co., Consolidated, United States. Improvements in the manufacture of compressed cakes of soap. June 20.

9659. J. S. Fairfax.—From F. Crane, United States. Improvements in or relating to the preparation of oils for compounding purposes. June 21.

9825. A. J. Boulton.—From G. Boulet fils, Donard, and Contamine, France. Improvements in or relating to apparatus applicable for the extraction of fatty substances from oil, sulphur, and other material, and for manufacturing extracts for dyes, and other purposes. June 24.

9856. G. Anderton, G. T. Barlow, and T. G. Marsh. Improvements in or connected with the bleaching or extracting colour from wax. June 25.

10,173. J. N. Zeitler. Process for producing hard and soft potash soaps and hard soda and potash soda soaps by spontaneous heating. July 1.

10,590. L. Roumieu. Improved process and apparatus for the extraction of oils from oleaginous seed or grain by means of volatile solvents. July 8.

10,753. A. F. St. George. Treatment of linseed and other oils employed in varnishes. July 11.

10,848. T. G. Croker. An improvement upon Brooke's soap. July 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

11,292. H. Enrich. Producing hard potash and similar soap from solid or liquid fats. July 16.

11,817. C. R. Huxley. Ammoniated soaps. July 2.

13,023. J. L. Moret. A solid product for removing grease, bleaching textile materials, fulling cloths, and removing hair from skins. July 2.

1890.

7854. A. W. Rhenstrom. Manufacture of soap. June 25.

8077. G. Allen. Composition of soap. July 2.

9062. C. D. Heustrom. Separation of fats from emulsions. July 16.

#### XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

##### APPLICATIONS.

9822. A. J. Boulton.—From W. Kiel, United States. Improvements in and relating to the manufacture of vulcanised plastic compounds. Complete Specification. June 24.

9897. J. Gordon. Improvements in making white pigments of lead. Complete Specification. June 26.

10,130. M. Alsberg. A new or improved process for producing minium. Complete Specification. July 1.

10,616. G. R. B. Kempton. An improved blue for laundry and other colouring purposes. Complete Specification. July 9.

#### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

##### APPLICATIONS.

9402. O. Potelune and O. Potelune and Co. New or improved machinery or apparatus for treating skins. June 17.

10,337. A. S. F. Grunbaum and T. B. Wood. An improvement in the manufacture of blood albumen. July 3.

10,706. S. Thorn. The production from raw hides of an article in substitution of what is commonly known as tanned leather. July 10.

## XV.—AGRICULTURE AND MANURES.

## COMPLETE SPECIFICATION ACCEPTED.

14,719. A. Manbré, sen. See Class XVII.

## XVI.—SUGARS, STARCHES, GUMS, Etc.

## APPLICATIONS.

10,331. A. Lefranc, L. Lefranc, and A. Vivien. Improvements in and connected with the manufacture of sugar. July 3.

10,449. W. R. Hutton. Improvements in saccharate of lime. July 5.

10,893. R. Pzillas. Apparatus for drying sugar or like substances. Complete Specification. July 12.

## COMPLETE SPECIFICATION ACCEPTED.

1889.

11,136. S. Pitt.—From L. W. Tracey. Apparatus for the treatment of cane juice. July 9.

## XVII.—BREWING, WINES, SPIRITS, Etc.

## APPLICATIONS.

9442. L. C. Best. Improvements in apparatus to facilitate the fining of beer. June 18.

9910. D. A. Bouallanger and A. Scheunert. Improvements in the process of and apparatus for purifying alcoholic liquids. June 26.

10,160. F. X. Kleinpeter. A new process for producing extract of malt or malt sugar in the malt grain. July 1.

10,436. W. P. Thompson.—From T. Bolland, Venezuela. Improvements in or relating to distilling apparatus for spirits and the like. July 5.

10,845. A. Boake and F. G. A. Roberts. An improved means of applying certain antiseptic agents to beer, wine, or other fermented drinks. July 12.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

10,667. W. W. Mutter and W. Dawson. Improvements in distillers' safes, also applicable for check-sampling spent wash at outlets of "patent" stills. July 2.

13,653. W. P. Thompson.—From P. Marix and N. Notkin. See Class II.

14,406. J. Hutchison. Treatment of alcoholic liquors. July 16.

14,719. A. Manbré, sen. Manufacture of spirit from grain and cereals, and treatment of by-products therefrom for production of cattle-food, charcoal, and manure. July 16.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

## APPLICATIONS.

*A.—Chemistry of Foods.*

9701. E. W. Hewett, jun. Bread-making with potatoes as the principal ingredient, and improvement therein. June 23.

10,004. E. McSwiney and S. J. Cluff. An improvement in preserving meat and other perishable goods by an antiseptic gas. June 18.

10,563. F. A. Raedler. Improved process for sterilising milk. July 8.

10,663. W. W. Bull and J. B. Baylis. New or improved manufacture of desiccated potato. July 9.

10,798. T. H. Poupon. An improved method of and apparatus for preserving meat, game, fish, vegetables, and the like. July 11.

*B.—Sanitary Chemistry.*

10,157. F. W. Shorey and C. R. Hudson. Separating the liquids from the solids in sewage and other like bodies. July 1.

10,229. A. Green. Improved means for decomposing sewage water by oxidising zinc by electric current. July 2.

10,313. F. Scudder. Improvements in the treatment of refuse material, such as town refuse, for obtaining valuable products therefrom. July 3.

10,451. C. G. Moor. An improved process for the recovery of ammonia from sewage sludge. July 5.

*C.—Disinfectants.*

9681. H. D. Booth. Disinfecting sinks, urinals, and the like with perforated disinfectant soap. June 21.

10,144. T. Sheppard and W. Sheppard. Preserving organic fluids. July 1.

## COMPLETE SPECIFICATIONS ACCEPTED.

*A.—Chemistry of Foods.*

1889.

11,806. W. Palmer. Preparation of a solid extract of meat and a preservative coating for same and other preserved foods. July 2.

13,438. C. A. Coombe. Treating brewers' grains, and manufacturing feeding cakes therefrom. July 2.

13,439. C. A. Coombe. Cattle-feeding cake. July 9.

1890.

8018. J. White. Jelly powder. July 2.

8354. W. C. H. Jessen. Preserving eggs. July 9.

*B.—Sanitary Chemistry.*

1889.

13,746. W. P. Buchan. Deodorising or disinfecting sewage and other polluted water. July 9.

1890.

7500. L. Hesse. Destructors for town and other refuse. July 9.

*C.—Disinfectants.*

1889.

13,203. J. T. MacMahon. Composition for arresting or preventing decay in wood. July 2.

## XIX.—PAPER, PASTEBOARD, Etc.

## APPLICATIONS.

9953. A. Gray. The manufacture of a new material to be called "Lacrepap," consisting of paper, wool, or cotton, separately or together, hardened or solidified by a process given herewith. June 27.

10,259. J. F. N. B. Simons and S. Smith. Improvements in the manufacture of paper pulp. July 2.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

- 13,657. M. Frisch. Press copying paper. June 25.  
 14,508. J. A. Causton and J. Challis. Process for applying luminous preparation to the surface of paper, &c. June 25.

1890.

5053. C. Kellner. Softening brittle paper pulp. July 9.  
 6348. H. H. Lake.—From J. H. Carpenter and C. E. O'Hara. Manufacture of coloured paper. July 16.  
 8422. O. Evanstad and O. Senstad. Apparatus for manufacture of wood-wool. July 9.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

## APPLICATION.

- 10,432. H. Lütke, L. Scholven, and L. F. Riedel. The manufacture of salicylate of phenyldimethylpyrazolone. July 5.

## COMPLETE SPECIFICATION ACCEPTED.

1889.

- 13,027. A. M. Clark.—From the Firm of F. von Heyden's successor. Separation of the isomeric substances produced in the manufacture of dithio-salicylic acid. July 2.

## XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

## APPLICATIONS.

9538. W. Rebikow. Improvements in the manufacture and production of emulsions and other materials sensitive to light. June 19.  
 9893. J. W. Swan and J. Leslie. Improvements in the manufacture of transparent flexible films for photographic and other purposes. June 26.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

- 10,353. J. S. Fairfax.—From F. Crane. Films or supports for photographic negatives or prints. July 2.  
 12,309. J. Williams. Treating paper, &c., to render it suitable for photographic purposes. July 2.

## XXII.—EXPLOSIVES, MATCHES, Etc.

## APPLICATIONS.

9315. E. N. Todd. Improvements in the process of manufacturing thin sheets of nitro-cellulose. Complete Specification. June 16.  
 9350. J. A. Goudge. The protection of gunpowder cartridges, fireworks, fire signals, and all solid explosives used for a similar purpose to gunpowder, from absorbing moisture. June 17.  
 9660. J. S. Fairfax.—From F. Crane, United States. Improvements in or relating to pyroxylic compounds. June 21.  
 10,025. W. M. Mordey. Improvements in electric safety fuses. June 28.  
 10,263. K. R. Malstrom. Improvements in percussion fuses. July 2.  
 10,321. A. J. Boulton.—From H. H. Rosenfeld, France. Improvements in the manufacture of matches. July 3.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

5614. Sir F. A. Abel and J. Dewar. Manufacture of explosives for ammunition. July 9.  
 11,500. P. Ward and E. M. Gregory. Fuses and detonators. July 9.  
 11,501. P. Ward and E. M. Gregory. Construction of electric fuses, and method and appliances for manufacturing same. July 16.  
 12,307. A. V. Newton.—From A. Nobel. Preparation and application of explosive compounds. June 25.  
 12,338. C. O. Lundholm and J. Sayers. Manufacture of explosives. June 25.  
 12,763. J. Lutz and L. Oltósy. Manufacture of lucifer matches. June 25.  
 13,486. C. O. Lundholm and J. Sayers. Making and applying explosives. July 16.  
 14,073. W. Clayton. Production of whistling fireworks. June 25.  
 14,804. H. Stephenson. Manufacture of certain fireworks for display purposes. July 16.

1890.

5364. J. R. France. Manufacture of nitro-cellulose, and apparatus therefor. July 9.

## NOTICES.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

## Journal and Patent\* Literature.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### PATENTS.

*Improved Apparatus for regulating the Flow of Compressed Gases.* A. T. Clarkson and J. B. Spurge, London. Eng. Pat. 11,518, July 18, 1889. 8d.

This invention relates more particularly to apparatus used for gases contained under pressure in vessels for transport, but it can also be used for other purposes where constant pressure is required to be obtained from a source sometimes greatly in excess, and variable in amount, and can be applied to the regulation of nitrous oxide for anæsthetic purposes, in the preparation of aerated waters, or for transporting or elevating liquids. Two sets of apparatus are used, which, though differing slightly in construction are the same in action, and are placed in communication with each other.

The first is intended to reduce any pressure ranging up to 150 atmospheres to any other that may be required, and consists of an expanding box having a flexible side or diaphragm pressed inwards by steel springs, which can be adjusted to counteract any pressure in the opposite direction, and has two openings communicating with the interior. To the diaphragm is also attached "scroll or cam-shaped pieces," actuating a valve and conical plug. The second apparatus is attached to the first by one of the openings alluded to, and differs from it mainly in the mode of fixing the valve. The effect of these improvements is said to "ensure efficient action over a greater range of pressures than hitherto, and at a less outlet pressure, the supply being maintained until the inlet pressure has fallen to one-third of an atmosphere."—E. S.

*Improvements in Filtering Apparatus.* J. M. Smales, Leavesden. Eng. Pat. 12,162, July 31, 1889. 8d.

A SOLID disc of metal or other material has radial or circular grooves on each side, and is covered with cotton cloth or other filtering medium. A circular opening is made in the centre, and round it is a boss having radial internal openings. A series of these discs is mounted on a hollow shaft having slots or holes, the discs being separated from each other by collars, and the whole set is placed in a cistern. The liquid to be filtered is admitted to the cistern, and passing through the filtering medium follows the course of the grooves to the holes in the boss, and into the hollow shaft by means of the holes therein, and flows out of the cistern. By communicating motion to the series of discs the deposit can be more readily washed off than when they are stationary.

—E. S.

*Improvements in Multiple-Effect Evaporating Apparatus for Evaporating or Concentrating Sugar Juice and other Liquids.* W. Maxwell, Djoeclja, Java. Eng. Pat. 12,809, August 14, 1889. 8d.

As compared with evaporators of ordinary construction the improvements consist (1) in substituting for the central internal tube two or more external circulating tubes connecting the upper and lower chambers, and passing outside

\* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d. ....	3d.
Above 8d., and not exceeding 1s. 6d. ....	1d.
" 1s. 6d., " " 2s. 4d. ....	1½d.
" 2s. 4d., " " 3s. 4d. ....	2d.

TO BE SUBSTITUTED FOR THE FIGURE ON PAGE 594 IN THE JUNE NUMBER OF THIS JOURNAL.

the tube chamber, thus allowing the space so obtained in the tube chamber to be utilised for additional heating surface; (2) in constructing the connecting pipe from the upper chamber of each evaporator to the tube chamber of the next, so that the inlet to the latter is deep in proportion to its breadth, and extends nearly the whole depth of the tube chamber; and (3) in arranging the tubes in the tube chamber so as to form one or more passages between them diverging from the inlet, and thus allowing the vapour entering by this inlet to have free access to the external surface of all the tubes. By these improvements it is stated that the heating medium readily reaches every part of the heating surfaces, while at the same time the greater rapidity with which the heating vapour is condensed, and the

diminished resistance to its flow, allow the evaporation in the liquid from which it arises to go on under a lower pressure and temperature.

There are five claims.—E. S.

*Improvements in Apparatus for Drying Earthy, Disintegrated, or Similar Materials.* V. F. L. Smidth, Copenhagen, Denmark. Eng. Pat. 12,863, August 14, 1889. 11d.

THE invention relates to apparatus for drying large quantities of small or disintegrated materials by means of hot air, and it may best be explained by reference to the accompanying drawing, which shows one modification of the apparatus.

It consists of a circular building or tower C of suitable height, closed at the top and fitted with a funnel *e* in the centre of the roof, through which the materials are fed. The funnel is surrounded by a shell C' open at the lower end and resting air-tight on the dome C' whilst connected by a flue with the exhaust fan *g*. From the floor of the tower rise one or more flues A to a convenient height, through which the hot air enters. They are surmounted by the truncated, spaced rings *m* and closed by the small dome B, which causes the hot air to pass through the spaces between the rings and through the body of the materials to be dried, assisted and directed by other rings and projections specially provided for that purpose in the annular space, as indicated by the letters L P k i and the arrows. The lower part of the walls of the tower C is perforated with openings *v* through which the dried material issues, and is thence removed mechanically in the following manner:—At the foot of the tower is a projecting ledge or step below the said openings *v*, which is encircled by a revolving ring D carried on and guided by suitable wheels or rollers. Attached to the ring are a number of scrapers *n*, and it is fitted with corresponding pockets *p* into which the material falls as it is brought forward by the continuous action of the scrapers. The pockets have side doors, closed by weights, which are raised by means of catches when they reach the point where the dried material is to be discharged. The material falls into a worm below, for conveyance to any desired point, whilst the vapour and gases are removed by the fan *g*.

The patentee makes two claims, and there are four sheets of drawings.—B.

*Improvements in and Relating to Vacuum Evaporating and Distilling Apparatus.* J. Foster, Sunderland. Eng. Pat. 18,153, November 13, 1889. 1s. 1d.

This invention consists of improvements in apparatus for evaporating, concentrating, and distilling sugar, caustic lyes, and other liquors in a vacuum (more or less) in vessels of the character of "triple or multiple effects." The improvements are specially applicable to the horizontal arrangements of apparatus described in Eng. Pat. 7343 of 1889. For the mode of construction and operation, the three sheets accompanying the specification must be consulted.

There are eight claims.—E. S.

*Improvements in or Appertaining to Pulverising Machines.* W. P. Thompson, Liverpool. From J. J. Bordinan, Brooklyn, U.S.A. Eng. Pat. 19,538, December 5, 1889. 8d.

This invention relates to improvements in pulverising machines, especially those provided interiorly with rotary fans and beaters, and refers more particularly to the balancing and adjusting of the shafts carrying the beaters and fans, the object being to provide means for overcoming the difficulties caused by the unequally wearing away or straining of certain parts in the working of the apparatus. This is done by effecting an immediate balance of the shaft at any desired moment, whenever the various parts of the beaters, fans, or internal mechanism become worn, by the use of sliding weights and moveable friction bearings. Full details are given in the drawing attached to the specification. There are seven claims.—E. S.

*Improvements in Asbestos Filters.* F. Breyer, Vienna, Austria. Eng. Pat. 5377, April 8, 1890. 8d.

The filtering medium employed is very finely divided asbestos, which has been sterilised by exposure to heated air. The disintegration of the asbestos, before it is made into an emulsion for application to the filtering bodies, is effected by moistening it with water, freezing the mass, and then reducing the frozen material.—E. G. C.

## II.—FUEL, GAS, AND LIGHT.

### PATENTS.

*Improved Process for Burning Petroleum and other Hydrocarbons, and Apparatus therefor.* W. P. Thompson, Liverpool. From J. Wilson, New York, and A. Mason, Brooklyn, U.S.A. Eng. Pat. 10,661, July 2, 1889. 11d.

The object of this invention is to so present the oil to the heating apparatus that perfect combustion ensues, and to obtain more heat from a given quantity of the material than by the usual means of supplying heat to atomise the petroleum, so that continuous uninterrupted combustion takes place; also to obtain a safe, continual, and economical heat for mechanical and other purposes.

Petroleum, or other oil or fatty substance, steam, and air, in proper proportion, are introduced, and the oil is thoroughly atomised and mixed with steam by impinging steam or air upon it, or oil upon steam or air, on its way to the flame. The air makes the combustion perfect, and may, when used without steam, be injected to produce the draught and spray the oil. The steam, when used, supplies the drawing or forcing power, and, in addition, the steam decomposes in the flame, and gives an additional element of heat in the evolving hydrogen and oxygen. This decomposition can be assisted and stimulated, as also the vapourising of the oil, by the use of superheated steam and hot air.

There are eight claims and one sheet of drawings.

—F. S. K.

*Improved Apparatus for Generating Gas or Vapour from Combustible Liquids.* J. Dheyne, Count V. de Nydprück, and P. de la Hault, Brussels, Belgium. Eng. Pat. 11,459, July 17, 1889. 8d.

The apparatus consists of a tank, charged with naphtha, petroleum, or the like, which flows off through a pipe ending in a coil, and the end of which is bent back in such a manner as to throw into the axis of the coil the gas escaping from the end. The coil is in contact with a metal surface or tube, and placed above a vessel or tray within which is burnt, for the purpose of starting the apparatus, any highly combustible liquid. The gas created by the heat of this combustion is ignited at the end of the coil, and the flame heats the latter up to a temperature which can be regulated by means of a cock, thus varying the quantity of gas escaping from the coil. In a second coil or worm, heated by the same flame, the vapour required for working a motive-power engine is generated. Modifications of the apparatus suitable for generating gas for heating purposes, or for supplying lamps, such as are employed in soldering and enamelling, are also described.—F. S. K.

*The Manufacture of an Improved Artificial Fuel.* J. Morris, London. Eng. Pat. 11,855, July 25, 1889. 4d.

The improved smokeless and inodorous fuel is prepared by mixing silicate of sodium, nitrate of potassium, water, powdered charcoal, powdered carbonate of lime, and powdered binoxide of manganese.

The whole is intimately mixed and then compressed into briquettes or bricks, and thoroughly dried at a low temperature.

The rate of combustion can be increased or diminished by increasing or diminishing the percentage of silicate of sodium. It is alleged that "this improved fuel being smokeless and inodorous, and giving off no noxious fumes, can be burned without a flue, and is, therefore, especially applicable for warming carriages, for rooms and other places which have no flues, and is very useful for heating greenhouses."

—F. S. K.

*Improvements in Incandescent Gas Burners.* C. Clamond, Paris, France. Eng. Pat. 12,091, July 30, 1889. 8d.

THE invention consists in an improved arrangement for heating a mixture of air and gas before burning them under a hood of magnesia filaments. A metal chamber divided by a horizontal wire gauze partition into two compartments carries on its upper surface a number of vertical copper or brass tubes open at both ends, and is fixed on a short Bunsen burner provided with suitable air-holes and connected with the gas supply by means of a cap covered with a small perforated plate. A perforated circular gallery for holding a chimney is fixed under the base of the chamber by means of a screwed piece of steatite or some other non-conducting material, the chamber and tubes are also surrounded by a metal casing rising a little above the level of the tubes. A conical cage of magnesia filaments is attached to a metal base fitting on the top of the casing and is held in position by wires of some refractory metal. The gas is ignited at the top of the tubes and raises the magnesia to incandescence; the flame is prevented from flashing back down the Bunsen burner, especially on ignition, by the wire gauze partition in the metal chamber, by a small conical hood screwed mouth downwards on the burner masking the air-holes, and by a saucer screwed on over the hood mouth upwards to intercept the flames from above.—S. B. A. A.

*Improvements in Retorts or Furnaces for the Distillation of Coal, or other analogous Purposes.* J. A. Yeadon and W. Adgie, Leeds. Eng. Pat. 19,183, November 29, 1889. 8d.

ACCORDING to the inventors, the apparatus described below dispenses with the labour of gas stokers, utilises the smallest size of coal, secures regular and continuous feeding and rapid and complete distillation of the fuel, and prevents waste of gas whilst charging or discharging the retorts.

The apparatus consists of a cylindrical or conical fire-clay or metallic retort, the body of which lies inside the furnace and rests on metal sockets, one at each end of the furnace. The sockets are turned up on the circumference where they are supported and revolve upon bearing rollers which have suitable shafts and revolve in metal frames outside the brickwork of the furnace; the whole of the circumference of the retort within the furnace is thus directly heated by the flames. The interior of the retort is made with a number of continuous blades running longitudinally through it, tapering from the front or feeding end towards the other extremity and preferably made solid with the shell; these serve to raise, break up, and gradually force the coal outwards, they also strengthen the retort. At the front end the retort is fitted with a mouthpiece or end-plate connected with a hopper, from the bottom of which coal is fed through a small cylinder projecting some distance into the retort and fitted with an internal shaft with adjustable blades; a diaphragm prevents the coal from working back. At the back end of the retort there is a vertical uptake for the gases and a vertical downtake for the coke; the latter communicates with the furnace grate and with the exterior and contains two sliding doors or valves so that the coke may either be charged on the furnace grate or drawn off into barrows, &c., without any escape of gas. Coal may be supplied to the hoppers and withdrawn from the furnace by means of elevators and endless conveyors. The disposition of some of the driving machinery, details of packing, and various modifications are described and illustrated in the specification.—S. B. A. A.

*Improvements in the Purification of Illuminating or Heating Gases.* W. C. Andrews, New York, U.S.A. Eng. Pat. 6800, May 2, 1890. 8d.

THE invention consists in passing the gas through a solid purifying material in a state of continual or intermittent agitation, or upwards through a shower of the finely divided material, or through successive horizontal layers

of the material, each layer periodically falling through the gas into the position of the layer next below it, the lowest layer being discharged as spent and fresh material supplied in the place of the uppermost layer. An apparatus for practically utilising this invention is described (see following abstract).—S. B. A. A.

*Improvements in Apparatus for the Purification of Illuminating Gas.* W. C. Andrews, New York, U.S.A. Eng. Pat. 6801, May 2, 1890. 8d.

THIS apparatus is adapted to the method of the preceding patent, Eng. Pat. 6800 (preceding abstract). It consists of a closed box or casing containing a series of horizontal rows of shafts parallel with the sides of the box, each shaft moving in bearings on the front and back walls of the box, and having on its upper surface a series of loops or eyes into which horizontal cross-pieces are fixed at right angles to the shaft, the cross-pieces on each shaft alternating with those on adjacent shafts. The spaces between the cross-pieces on the shafts next the sides of the box are partially occupied by a series of slats or short rods fixed to each side; each row of shafts, cross-pieces and slats thus forms a grating or broken platform for the reception of the purifying material. Cranks are attached to one end of each shaft which projects from the box, and a long lever is attached to the ends of each row of cranks. It is evident that any motion of this lever will cause the cross-pieces on the shafts to oscillate and agitate or shake off any matter deposited on them. Two hoppers closed by valves are fixed under the bottom of the box for the reception of the spent material from the lowest platform. Gas is supplied from below and drawn off from the top of the apparatus. The box may be as much as 24 ft. in depth, the horizontal shafts in each row about 1 ft. 6 in. apart, the cross-pieces slightly less than 3 ft. in length, with from 1 in. to 1.5 in. space between adjoining strips. The platforms being covered with purifying material, gas is allowed to enter; one or more of the rows of shafts may then be rocked either continually or when the issuing gas is recognised to be wanting in purity, or they may be left at rest for the most part, and only used to clear the lowest layer to the hopper, and then to remove each succeeding layer in on to the platform below it, fresh material being supplied to the uppermost platform.—S. B. A. A.

*Improvements in Apparatus for the Production and Application of Gases for Metallurgical and other Purposes.* J. J. Shedlock, New Barnet, and J. J. Meldrum, Manchester. Eng. Pat. 6864, May 3, 1890. 6d.

See under X., page 811.

*Improvements in Combustible Coal Bricks.* J. J. Hiertz, St. Louis, U.S.A., and A. S. Garnett, Hot Springs, Ark., U.S.A. Eng. Pat. 6877, May 3, 1890. 6d.

SLACK, dust, or waste of lignite or brown coal is thoroughly dried, and to every ton of combustible is added a compost consisting of 1 bushel of quicklime, slaked and thoroughly incorporated with 7 galls. tar, 25 lb. salt, and 1 gall. of turpentine. The mixture is thoroughly worked together, heated to a temperature sufficient to cause the intimate fusion of all the ingredients, and submitted in hot moulds to a pressure of three tons per square inch.

Bituminous coal may be similarly treated, a smaller proportion of tar and turpentine being used, with a higher temperature during the moulding. It is claimed that these bricks are very economical, and that having a glazed surface they are cleanly and impervious to moisture, moreover they burn with little smoke or ash.—S. B. A. A.

*Improvements in Coke-Ovens.* W. Fritsch, Zabrze, Germany.  
Eng. Pat. 13,390, August 24, 1889. 8d.

THE object of this invention is to facilitate the uniform heating and regulation of the temperature of the coke chambers in horizontal ovens. This is effected as follows:—The air required for combustion is supplied by a blower into side channels *g* in the basement of the oven, passes into a central channel *h*, and then through narrow inclined passages *i* into air-heating spaces *k* provided with horizontal baffle-walls *l*, and situated below the chamber walls between the channels *v* which carry away the products of combustion and serve to heat the bottoms of the coke chambers *p*. On leaving these spaces the air is caused to flow in a direction contrary to that of the gases, and is then admitted

to the combustion chambers *r* through a number of openings progressively increasing in size  $o^1 o^2 o^3 o^4$ , the largest of which ( $o^4$ ) is situated nearest the outer end of the chambers where the gases are also introduced. It is controlled by a damper *n*, by means of which the intense combustion which takes place around the outer end of the coke chamber may be transferred to the interior. When the by-products are collected, the gases after condensation are introduced at both ends of the combustion chambers (*d*); otherwise the gases are directly conducted to the chambers at each end of the oven and thence past adjustable dampers into the combustion chambers. The latter are provided with vertical baffle-walls, and the products of combustion are drawn off through channels *v* into the main flue *F*.—S. B. A. A.

*Para-nitro-orthotoluene Sulphonic Acid.* J. Hausser. Bull. Soc. Chim. 1890, 797—799.

This acid was described by Beilstein and Kuhlberg (Ann. 155, 8), and some of its salts were prepared by Jensen (Ann. 172, 230). It may be prepared by gradually dissolving 200 grms. of paranitrotoluene in 260 grms. of sulphuric acid (44 per cent.  $SO_3$ ), the mass being kept cool at first but heated towards the finish to a temperature not exceeding  $150^\circ$ . The product is poured into water (1,500 grms.), heated, the sulphuric acid removed with powdered calcium carbonate and the filtrate concentrated and allowed to crystallise. The yield is about 64 per cent. The ammonium salt crystallises in long white anhydrous prisms and the sodium salt in prisms containing 2 mols. of  $H_2O$  which however it loses below  $130^\circ$ . Neither of these salts is affected by either strong or dilute sulphuric acid even at  $100^\circ$ . The sulphonic acid possesses very powerful acid properties, displacing sulphuric acid from soluble sulphates, even in the cold; a copper and a zinc sulphate were prepared in this manner. Nitrotoluene metasilphonic acid appears to possess similar properties to its isomeride.

—S. B. A. A.

*The Connection between Chemical Constitution and Colour.* F. Kehrman. Chem. Zeit. 14, 508, 527, 541—542.

THE introduction into the nucleus of an aromatic hydrocarbon of two carbonyl-groups in either the ortho- or para-position is accompanied by the appearance of a more or less intense yellow colour in the compound produced, the *o*-quinones being invariably of a deeper tint than the corresponding *p*-quinones, as is seen in the cases of  $\beta$ - and  $\alpha$ -naphthoquinone, phenanthraquinone and anthraquinone.

Again, the ordinary azo-compounds containing the group  $R-N=N-R$  stand to the azines of the type—

in the same relation as do *o*-quinones to *p*-quinones, the colours of these compounds confirming this view, for the azo-hydrocarbons are yellow or orange whilst the azines are pale yellow or colourless. The influence on the colour-property of quinone compounds due to the presence of positive or negative radicles in the molecule has been studied with respect to *p*-quinones solely, as very little is known regarding such derivatives of *o*-quinones. The following laws, consequently, refer to *p*-quinones.

I. The presence of alkyl-groups in the quinone molecule exercises no essential influence on the colour of the compound; compare, for instance, the colours of benzoquinone, toluquinone, thymoquinone,  $\alpha$ -naphthoquinone, anthraquinone.

II. Halogen-groups affect the colour in direct proportion to their atomic weights. Thus, the effect of iodine is well-marked, red-coloured compounds being formed, all the iodoquinones being of a deep red tint; bromine has a less powerful effect, orange-coloured bodies being produced as in the case of the two bromothymoquinones; chlorine, again, has very little colouring influence, mono-, di-, tri-, and tetra-chloroquinone being of the same hue as quinone itself. Although the influence of fluorine is unknown, it may be conjectured that its derivatives will be coloured similarly to, though perhaps paler than, the corresponding chlorine compounds.

III. Alkoxyl-groups have a reddening influence; methoxy-, ethoxy-, and dimethoxy-quinones have an orange colour; *p*-dichlorodimethoxyquinone and the corresponding ethoxy-compound a deep red.

IV. Less decided is the reddening effect of acetamido-groups, *m*-diacetamidoquinone being orange yellow and *p*-diacetamidoquinone orange.

V. Quinones containing nitro-, carbonyl-, sulphy-, cyano-, and other strongly negative radicles do not apparently exist, or at least are very unstable, except in the presence of hydroxyl- and amido-groups; thus, hydroquinone-carboxylic acid on oxidation decomposes into quinone and carbon dioxide and nitrohydroquinone cannot be oxidised to nitroquinone. Hydroxyquinones, on the other hand, can be nitrated or sulphonated, the effect of such operations being to change the colour of the compound from red to yellow, as is seen, for instance, in the cases of *p*-dihydroxyquinone and nitranilic and eithiochromic acids; the slightly negative acetyl-group shows a similar effect, *p*-diacetyl-tetrahydroxyquinone, for example, being yellower than *p*-dihydroxyquinone.

VI. The effect of the hydroxyl-group varies according as it is present in the quinone-molecule alone or in conjunction with other groups. The effect also changes regularly when the compound is converted into a salt, an ether, or an ester.

(a.) In general the presence of the hydroxyl-group intensifies the colour to red or violet, the particular tint depending upon the position of the substituting groups, and above all, on the number of such groups. A single OH-group effects only a slight, frequently inappreciable, deepening of the yellow hue, hydroxynaphthoquinone and hydroxythymoquinone, for example, are of the same colours respectively as  $\alpha$ -naphthoquinone and thymoquinone; *o*-hydroxyanthraquinone is orange-red, *m*-hydroxyanthraquinone yellow. Two hydroxyl-groups, however, produce a considerable deepening of colour, *p*-dihydroxyquinone being coloured deep orange-red,  $\beta$ - $\beta$ -dihydroxy- $\alpha$ -naphthoquinone brown-red, naphthazarin dark blood-red, alizarin orange. Still further increase in the number of hydroxyl-groups intensifies the tint to violet-black; thus, crystallised tetrahydroxyquinone is pitch-black, in powder violet.

(b.) The simultaneous presence of other groups in hydroxyquinones causes the effects on the colours of the resultant compounds stated below.

(1.) Alkyl-groups are without sensible influence on the colour of hydroxyquinones; *p*-dihydroxyquinone, *p*-dihydroxytoluquinone, and *p*-dihydroxythymoquinone are of almost the same tint. (2.) Halogen-groups exert a reddening action, proportionally stronger with increase of atomic weight; thus, *p*-dihydroxyquinone is orange-yellow, its monochloro-derivative orange, chloranilic acid scarlet, and iodoanilic acid deep red. (3.) Nitro- and sulphy-groups alter the tint from red to yellow; all the nitrohydroxyquinones, for instance, are yellow; nitranilic acid is golden-yellow, nitrohydroxy- $\alpha$ -naphthoquinone pale yellow, eithiochromic acid, as its name signifies, of a fine yellow colour. (4.) The acetamido-group has a slightly greater reddening action than the halogen-group; acetamidohydroxynaphthoquinone, for example, is of a redder yellow shade than chlorohydroxynaphthoquinone. (5.) The amido-group turns violet the hydroxyquinone which contains it; hydroxynaphthoquinone is golden-yellow, amidohydroxynaphthoquinone dark purple. (6.) The phenylazo-group masks the colouring influence of the quinone group; the compounds formed having the colour of hydroxyazobodies.

(c.) Respecting the effect of substitution of the hydroxyl-hydrogen, it is observed that whilst (1), etherification causes no particular change of tint, and (2) esterification renders paler the colour of hydroxyquinones, (3) the substitution of such hydrogen-atoms by metals causes a change of colour from yellow to deep red.

The power possessed by certain hydroxyquinones of dyeing on mordants depends on their property of forming coloured salts; thus, orange-coloured alizarin forms salts varying in colour from crimson to blue; the alkaline salts of purple amidonaphthalic acid are of an indigo-blue colour; scarlet chloranilic acid yields violet-red salts. Such hydroxyquinones as are chemically unacted upon by alkalis, dissolve in solutions of the same with colourations varying from blood-red to green.

VII.—Free amido-groups in quinone-compounds always produce a deepening in the colour of the same from yellow to red, brown, purple, or blue; thus *p*-diamidoquinone is purple, bromamidonaphthoquinone orange-red, the amido-anthraquinones blood-red to dark blue. Replacement of the hydrogen in the amido-group by alkyl- or phenyl-groups has no effect on the colour. Acetylation of the amido-group, and combination of the same with acids, change the tint from red to yellow, purple-coloured amidohydroxy- $\alpha$ -naphthoquinone yields with hydrochloric and sulphuric acids pale yellow-coloured salts of the tint of hydroxy- $\alpha$ -naphthoquinone.

The introduction of amido- or hydroxyl-groups into nitro-compounds results in a deepening of the colour of the same; the nitranilines, for example, are orange, whilst nitrobenzene is almost colourless; *p*-nitrotetrahydroxytoluene, again, forms a purple powder.

In general, if the atomic complex combined with the quinone-group be, on the whole, positive, the colour of the compound is red or violet, whereas, if it be negative, the colour of the compound is yellow.—E. B.

*Studies on the Constitution of the Tri-Derivatives of Naphthalene. No. 4. The Constitution of  $\alpha$ -Naphthylaminedisulphonic Acid* Dahl No. 11. *Naphthalene-1:2'-Disulphonic Acid*. H. E. Armstrong and W. P. Wynne. Proc. Chem. Soc. 1890 (86), 125—126.

WHEN naphthionic acid is sulphonated with 35 per cent. anhydrosulphuric acid at a temperature not exceeding 30° according to Dahl and Co.'s German patent No. 41,957, 1886, two disulphonic acids are produced, which are respectively known as  $\alpha$ -naphthylaminedisulphonic acid No. II. and No. III., the latter constituting the chief product. The constitution of acid No. III. has been given in a previous communication (this Journal, 1890, 283). With the object of comparing the disulphonic acids obtained by the sulphonation of  $\alpha$ -naphthylamine with those known to be produced by the sulphonation of  $\alpha$ -naphthol, the

authors have undertaken the investigation of acids Nos. I. and II. of Dahl and Co.'s patent, and are now in a position to communicate the results obtained by the examination of acid No. II.

The product was in the form of potassium salt, and on investigation was found to contain a noteworthy quantity, perhaps 20 per cent., of an  $\alpha$ -naphthylaminetrisulphonic acid, the formation of which, under the conditions above named, is specially interesting as throwing further light on the process involved in the production of isomeric disulphonic acids. When reduced by the hydrazine method, this  $\alpha$ -naphthylaminetrisulphonic acid yielded a *naphthalenetrisulphonic acid* characterised by forming a *chloride*,  $C_{10}H_7(SO_2Cl)_3$ , which crystallised from a mixture of benzene and petroleum spirit in small prisms melting at about  $191^\circ$ . By the Sandmeyer method it was converted into a *chloronaphthalenetrisulphonic acid* characterised by forming a *chloride*,  $C_{10}H_4Cl(SO_2Cl)_3$ , which crystallised from benzene in minute prisms from a mixture of benzene and petroleum spirit in small crystalline aggregates, and from acetic acid in small scales melting at  $215^\circ$ .

$\alpha$ -Naphthylaminedisulphonic acid No. II., on conversion into naphthalenedisulphonic acid by v. Baeyer's hydrazine method, yielded a new acid, the salts of which will be described in a subsequent communication. This acid was found to be the 1:2'-disulphonic acid, and is the *sixth* known naphthalenedisulphonic acid. It was proved that  $\alpha$ -naphthylaminedisulphonic acid Dahl No. II. is a sulphonated naphthionic acid, and has the constitution—

Dahl acid No. II.

The authors reserve the investigation of the properties of the 1:2'-naphthalenedisulphonic acid and its derivatives.

*No. 5. The Constitution of the Schöllkopf  $\alpha$ -Naphthylaminedisulphonic Acid.* H. E. Armstrong and W. P. Wynne. Proc. Chem. Soc. 1890 (86), 126—127.

THE formation of the Schöllkopf  $\alpha$ -naphthylaminedisulphonic acid (German Patent 40,571) by the nitration and subsequent reduction of the authors' naphthalene-1:4'-disulphonic acid (Bernthsen, this Journal, 1890, 491) renders it evident that the generally accepted view of the constitution of this acid is a correct one. Having been favoured by the Actiengesellschaft für Anilinfabrikation with a supply of the material prepared by the method given in the Schöllkopf patent, the authors took occasion to submit this to examination. They found that it was converted by the hydrazine method into naphthalene-1:4'-disulphonic acid, which was characterised by conversion into the chloride crystallising from benzene in prisms melting at  $182^\circ$ , and into 1:4'-dichloronaphthalene melting at  $107^\circ$ . On treatment by the Sandmeyer process it gave a chlorodisulphonic acid, the *chloride* of which crystallised from acetic acid in very small prismatic needles which became opaque on drying, and from a mixture of petroleum spirit and benzene in sparingly-soluble glistening flat plates. It melted at  $135^\circ$ , and on distillation with  $PCl_5$  was converted into  $\delta$ - or 1:4:1'-trichloronaphthalene melting at  $131^\circ$ . These results place it beyond question that the constitution of the Schöllkopf acid is expressed by the formula—

*No. 6. The Constitution of Cassella's  $\beta$ -naphthylamine- $\delta$ -disulphonic Acid.* H. E. Armstrong and W. P. Wynne. Proc. Chem. Soc. 1890 (86), 127—128.

MESSRS. CASSELLA and Co. having been good enough to furnish the authors with a supply of their  $\beta$ -naphthylamine- $\delta$ -disulphonic acid, prepared from the  $\beta$ -naphtholdisulphonic acid of their German Patent No. 44,079, it has been possible to determine its constitution by the hydrazine and Sandmeyer methods already described. On treatment by the hydrazine method, the amido-acid yields, in the first instance, a peculiar rosy, gelatinous, hydrazine, which can only be freed from tin salts with considerable difficulty. The disulphonic acid obtained from this hydrazine yields a chloride crystallising from benzene, in which it is sparingly soluble, in small, flat spear-like needles. This chloride melts at  $225^\circ$ , and on distillation with  $PCl_5$  yields 2:3'-dichloronaphthalene melting at  $135^\circ$ ; it is, therefore, naphthalene-2:3'-disulphonic acid—the  $\beta$ -disulphonic acid of Ebert and Merz. By the Sandmeyer method the amido-acid is converted into a chlorodisulphonic acid, the *chloride* of which crystallises from benzene, in which it is very soluble, in small, characteristic radiate groups of very slender needles, and from a mixture of petroleum spirit and benzene in small, opaque aggregates melting at  $176^\circ$ . On distillation with  $PCl_5$  it yields 2:3:2'-trichloronaphthalene melting at  $90^\circ$ . Combining these results, it follows that Cassella's  $\beta$ -naphthylamine- $\delta$ -disulphonic acid and the  $\beta$ -naphtholdisulphonic acid of the German Patent No. 44,097, from which it is derived, have the formula—

and both are, therefore, tri- $\delta$ -acids isomeric with the corresponding R-acids (this Journal, 1890, 283).

*No. 7. The Disulphonic Acids obtained by Sulphonating the Isomeric Heteronuclear  $\beta$ -Naphthylaminesulphonic Acids.* (First notice.) H. E. Armstrong and W. P. Wynne. Proc. Chem. Soc. 1890 (86), 128—131.

ACCORDING to Gans and Co.'s German Patent, No. 35,019, 1884,  $\beta$ -naphthylamine is converted into the amido-G-disulphonic acid by heating its sulphate with thrice its weight of 20—30 per cent anhydrosulphuric acid at  $110^\circ$ — $140^\circ$  until soluble in water; and the same product is said to result when " $\beta$ -naphthylaminesulphonic acid" is similarly treated. But inasmuch as four monosulphonic acids are obtainable from  $\beta$ -naphthylamine, to determine the law of sulphonation, it was obviously necessary to examine the behaviour of each of these, and to avoid the occurrence of secondary changes as far as possible. Experiments with this object in view were commenced several years ago. Meanwhile, an account of the behaviour of the Brönner acid under conditions similar to those specified by Gans and Co., have been published by Forsling (*Ber.* 1888, 3496).

(1.) 2:1'- $\beta$ -naphthylamine- $\alpha$ -sulphonic Acid (*Badische Acid*).—When the *Badische* acid is stirred into four times its weight of 20 per cent. anhydrosulphuric acid at a temperature not exceeding  $20^\circ$ , and the mixture is allowed to stand, sulphonation proceeds slowly, and is not entirely complete even at the end of three months. The product is found to consist almost entirely of an acid recognised as amido-G-disulphonic acid, inasmuch as it gave by the hydrazine and Sandmeyer methods all the products already described as characteristic of this acid (this Journal, 1890, 283). The naphthalenedisulphochloride prepared from it melted at  $137^\circ$ , and on distillation with  $PCl_5$  gave 1:3-dichloronaphthalene melting at  $61.5^\circ$ . The chloronaphthalenedisulphochloride from it melted at  $169^\circ$ , and on distillation with  $PCl_5$  gave 1:3:2'-trichloronaphthalene melting at  $113^\circ$ .

(2.) 2:4'- $\beta$ -naphthylamine- $\alpha$ -sulphonic Acid (*Dahl Acid*).—When stirred into four times its weight of 20 per cent. anhydrosulphuric acid at a temperature not exceeding

20°, the Dahl acid gradually undergoes further sulphonation, the process being usually completed in from 116—120 hours. The product is found to consist of two isomeric acids, which are readily separated by crystallising out the minor product as normal potassium salt, and subsequently purifying the chief product by repeated crystallisation of its acid potassium salt.

**Chief Product.**—The acid potassium salt of the chief product on reduction by the hydrazine method gave naphthalene-1:3-disulphonic acid, and was proved to have the constitution—

**Minor Product.**—The normal potassium salt of this acid on distillation with  $\text{PCl}_5$  is converted into 1:2:4'-trichloronaphthalene, crystallising from alcohol in long, slender, flat needles melting at 78°—78.5° (Proc. Chem. Soc. 1889, 49). It follows, therefore, that this amido-acid has the constitution—

(3.) **2:3'-β-Naphthylamine-β-sulphonic Acid (Brønner Acid).**—When stirred into four times its weight of 20 per cent. anhydrosulphuric acid at a temperature not exceeding 20°, the Brønner acid is readily further sulphonated, the process being completed in from 16—20 hours. The product is found to consist of two isomeric acids; the minor product, perhaps 20 per cent., has been identified as G-amido-disulphonic acid by the hydrazine and Sandmeyer methods.

**Chief Product.**—The acid potassium salt of this acid crystallises in opaque, white radiate aggregates of short needles, difficultly soluble in water; but the crystalline form and solubility are much influenced by the presence of small quantities of amido-G-acid, and there is every reason to regard it as identical with the acid obtained by Forsling (Ber. 1888, 3496) by heating Brønner acid with 3 to 4 parts of "fuming sulphuric acid" (percentage of added  $\text{SO}_3$  not stated) at 110° until the product was soluble in water. When reduced by the hydrazine process, the amido-acid constituting the chief product gave naphthalene-1:3'-disulphonic acid. On treatment according to the Sandmeyer method, it was converted into a chlorodisulphonic acid, which on distillation with  $\text{PCl}_5$  gave 1:2:3'-trichloronaphthalene. Combining these results, the amido-acid constituting the chief product, and presumably Forsling's acid, has the constitution—

By operating at higher temperatures the yield of this acid is diminished, and that of the amido-G-acid increased.

(4.) **2:2'-β-Naphthylamine-β-sulphonic Acid (Bayer and Duisberg's delta-acid).**—When stirred into four times its weight of 20 per cent. anhydrosulphuric acid at a temperature not exceeding 25°, delta-acid yields a complex product, which has not yet been satisfactorily separated into its constituents.

**No. 8. β-Chloronaphthalenedisulphonic Acids.** (First notice.) H. E. Armstrong and W. P. Wynne. Proc. Chem. Soc. 1890 (86), 131—133.

As already indicated in a previous communication, the study of the disulphonic acids obtained by sulphonating chloronaphthalenesulphonic acids of known constitution is

being carried on *pari passu* with that of the acids derived from the various naphthylaminesulphonic acids (this Journal, 1890, 284). A brief account of the results obtained with the four heteronuclear β-chloronaphthalenesulphonic acids under like conditions is now given, details with reference to the composition of the salts, &c. being reserved for a full communication. Sulphonation was effected by adding the theoretical quantity of sulphuric anhydride, employed in the form of 20 per cent. anhydrosulphuric acid, to the dry potassium β-chloronaphthalenesulphonate and heating the warm mixture at 100° for an hour, the potassium sulphate formed being removed by treatment with alcohol and the excess of sulphuric acid by means of barium carbonate.

(1.) **2:1'-β-Chloronaphthalene-α-sulphonic Acid.**—This acid, under the conditions named, gives a uniform chloronaphthalenedisulphonic acid, the *chloride*,  $\text{C}_{10}\text{H}_7\text{Cl}(\text{SO}_2\text{Cl})_2$ , of which crystallises from benzene, in which it is comparatively sparingly soluble in beautiful radiate groups of long, slender, lustrous needles. It melts at 170°, and on distillation with  $\text{PCl}_5$  gives 1:3:2'-trichloronaphthalene melting at 113°. The constitution of the acid is therefore—

and corresponds with the G-amido-acid obtainable from the 2:1'-β-naphthylamine-α-sulphonic acid.

(2.) **2:4'-β-Chloronaphthalene-α-sulphonic Acid.**—This acid gives what seems to be a uniform product. The potassium salt of the chlorodisulphonic acid is particularly well characterised, since it crystallises in prismatic forms, whereas the corresponding salts of the isomeric acids crystallise in slender needles. The *chloride*,  $\text{C}_{10}\text{H}_7\text{Cl}(\text{SO}_2\text{Cl})_2$ , is apparently dimorphous, and crystallises from benzene for the most part in very lustrous scales, but occasionally in prismatic forms, both of which melt at 156°—156.5°, and on distillation with  $\text{PCl}_5$  give the same trichloronaphthalene melting at 79°. This trichloronaphthalene has not yet been compared by sulphonation, &c. with the 1:2:4'- and the 1:3:3'-trichloronaphthalenes, with one of which it must be identical, owing to the insufficient supply of material; most probably it has the constitution 1:3:3'- and corresponds with that derived from the amido-acid constituting the chief product of the further sulphonation of the 2:4'-β-naphthylamine-α-sulphonic acid.

(3.) **2:3'-β-Chloronaphthalene-β-sulphonic Acid.**—Under the conditions named, this acid gives two chlorodisulphonic acids which are best separated by the fractional crystallisation of the potassium salts. The less soluble potassium salt constituting the minor product yields a *chloride*,  $\text{C}_{10}\text{H}_7\text{Cl}(\text{SO}_2\text{Cl})_2$ , which crystallises from benzene in very slender needles aggregated in prismatic forms, having a silky lustre; it melts at 148°, and on distillation with  $\text{PCl}_5$  gives 1:3:2'-trichloronaphthalene, crystallising from alcohol in characteristic tufts of needles melting at 113°.

The more soluble potassium salt constituting the major product was found to give products identical with those obtained from the chlorodisulphonic acid derived from 2:1'-β-chloronaphthalene-α-sulphonic acid (*vide supra*). The *chloride* crystallises from benzene in radiate groups of needles melting at 169°, and on distillation with  $\text{PCl}_5$  yields 1:3:2'-trichloronaphthalene melting at 113°. The constitution of the two acids is represented by the formulae—

Minor product.  $\text{Cl}(\text{SO}_2\text{Cl})_2$ , m.p. = 147°. Major product.  $\text{Cl}(\text{SO}_2\text{Cl})_2$ , m.p. = 169°.

(4.) **2:2'-β-Chloronaphthalene-β-sulphonic Acid.**—This acid, under the above conditions, yields a uniform chlorodisulphonic acid, the *chloride* of which,  $\text{C}_{10}\text{H}_7\text{Cl}(\text{SO}_2\text{Cl})_2$ ,

crystallises in beautiful radiate groups of flat, prismatic needles, melting at  $174^{\circ}$ . On distillation with  $\text{PCl}_5$ , the chloride is converted into 1 : 3 : 3'-trichloronaphthalene, crystallising from alcohol in radiate groups of long, slender needles, melting at  $80.5^{\circ}$ . The acid has, therefore, the constitution—

*The Comparative Influence Exercised by the Radicles Cl, OH, and  $\text{NH}_2$  in Naphthalene Derivatives on the Formation of Disulphonic Acids.* II. E. Armstrong and W. P. Wynne. Proc. Chem. Soc. 1890 (86), 133—136.

THE results obtained by the comparative study of the influence exercised by radicles such as Cl, OH, and  $\text{NH}_2$  on the formation of disulphonic acids, of which an account has been given in the foregoing notes and in previous communications by the authors, are such as to throw much light on the laws which govern substitution in the naphthalene series and are moreover highly suggestive. The results obtained in the case of the chloro- and amido-acids are collected in the following diagram :—

One fact to which attention may be directed, which appears to be most clearly established by the investigation of a very large number of disulphonic acids, is the "invincible objection" of two sulphonic radicles to remain in either contiguous or para- or peri-positions. The expression "remain in" is used advisedly, as the authors believe that, inasmuch as action more often than not takes place in the first instance in accordance with the so-called  $\alpha$ -law to which they have repeatedly directed attention, such positions are sometimes initially assumed by two sulphonic groups. It is a question whether the final acquisition of other positions than  $\alpha$ -positions is a consequence of direct isomeric change, or of the formation of higher sulphonic acids and their subsequent partial hydrolysis.

Different radicles undoubtedly exercise a very different and most important influence in determining such secondary changes. Thus  $\beta$ -naphthol on treatment with sulphonating agents is converted into a sulphate which very readily undergoes isomeric change into the 2 : 3'-sulphonic acid;  $\beta$ -naphthylamine sulphate undergoes a similar change, but much less readily, being converted into the 2 : 3'-sulphonic acid only after long heating at a high temperature: in this latter case the formation of the sulphamic acid probably precedes that of the sulphonic acid, and either the

sulphamic acid is formed with difficulty from the sulphate, or, when formed, does not readily undergo isomeric change.

$\alpha$ -Naphthylamine and  $\alpha$ -naphthol differ in a similar manner.

When excess of sulphuric acid is used, opportunity is given for sulphonation to pursue a different course: the characteristic properties of the phenol and amine are, in a sense, obliterated, owing to the formation of sulphates, and these sulphates behave much as do corresponding derivatives containing a neutral radicle-chlorine, for example. Then, if  $\beta$ -naphthyl sulphate be sulphonated by  $\text{SO}_3\text{HCl}$  without application of heat, a disulphonic acid is at once obtained, which, there is reason to believe, has the constitution—

(Ber. 15, 204); the formation of this compound affords the most significant indication of the course of change; evidently the homo- $\alpha$ -hydrogen atom contiguous to the  $\text{O}.\text{SO}_3\text{H}$ -group of the sulphate is first displaced; the resulting sulpho-sulphate, however, spontaneously undergoes isomeric change.  $\beta$ -naphthylamine sulphate, apparently, behaves somewhat differently, yielding the 2 : 1'- and 2 : 4'-monosulphonic acids; in this case the  $\text{NH}_2.\text{H}_2\text{SO}_4$  group may be supposed to remain unchanged; but it is not improbable that the homo- $\alpha$ -hydrogen atom contiguous to this group is primarily displaced by  $\text{SO}_3\text{H}$ , which then passes spontaneously into the contiguous peri- $\alpha$ -position, giving rise to the 2 : 1'-acid; the formation from the 2 : 3'- and 2 : 4'-monosulphonic acids of disulphonic acids containing the  $\text{SO}_3\text{H}$ -group in the homo- $\alpha$ -position contiguous to the  $\text{NH}_2$  affords the strongest support to this view. The formation of the 2 : 4'-monosulphonic acid from  $\beta$ -naphthylamine sulphate is perhaps the outcome of an independent action.

In the case of  $\beta$ -chloronaphthalene, it is conceivable that the 2 : 1-sulphonic acid is the immediate product, and that this spontaneously changes into the 2 : 1'-acid which is actually obtained as chief product; the 2 : 3'-acid which is obtained as subsidiary product may be formed by spontaneous isomeric change from 2 : 4'-acid initially produced on sulphonation rather than by the isomeric change of the 2 : 1'-acid at the moment of formation; this view being supported by the fact that  $\beta$ -iodonaphthalene affords a small proportion of 2 : 4'-acid (Proc. Chem. Soc. 1889, 120).

In short, it is not impossible that the  $\beta$ -mono-derivatives all behave similarly on sulphonation, acting in a minor degree as naphthalene itself would, but chiefly as mono-derivatives; and that the differences in the structure of the ultimate products are due to the different manner in which secondary change takes place under the diverse influences of various  $\beta$ -radicles. The same argument would apply to  $\alpha$ -compounds.

The peculiar differences manifest in the case of monosulphonic compounds are also to be noted in the case of disulphonic (see diagram)—the product of further sulphonation is, as a rule, simpler in the case of the chloro-acid than in the case of the amido-acid; and change proceeds further in the case of the hydroxy- than in that of the  $\text{NH}_2$ -compound, as is evidenced by the formation of R- together with G-disulphohydroxy acid under conditions which do not give rise to R-amidodisulphonic acid.

In the case of the 2 : 1'-amidodisulphonic acid, the homo- $\alpha$ -position contiguous to the  $\text{NH}_2$  is, perhaps, screened from attack; and either a 1 : 4-disulphonic acid is first formed, or, under the dehydrating influence of the sulphuric acid present in excess, a sulphamic-sulphonic acid is gradually produced, which then undergoes isomeric change: it appears not improbable, from the exceptionally slow manner in which sulphonation takes place, that the latter is the correct explanation.

The remaining three isomeric  $\beta$ -amidodisulphonic acids, in all probability, are at an early stage—for it is possible that a sulphamic acid is the first product of sulphonation—if not initially converted into 2 : 1-homosulpho-derivatives; but it is a question whether these then undergo a simpler isomeric

change, or whether the final products are formed from them by their conversion into higher sulphonie acids which then suffer hydrolysis. The behaviour of 1:2-chloro- $\beta$ -naphthylamine on sulphonation (Proc. Chem. Soc. 1889, 36, 48) appears rather to support this latter view, as the passage of the sulphy-group through the positions  $1 \rightarrow 2 \rightarrow 3$  takes place with a much greater facility than is usual in cases of non-spontaneous isomeric change. It is true that the conditions under which sulphonation is effected are such that no water is present; but, bearing in mind the tendency of  $H_2SO_4$  to combine with  $SO_3$ , it is by no means improbable that  $H_2SO_4$  itself may effect the hydrolysis.

Lastly, attention may be called to the occurrence of "homo-sulphonation" in the case of the two chloro- $\beta$ -sulphonie acids; the products in question are, perhaps, direct sulphonation-products, but it is also conceivable that the 2:1-chlorosulphonie acid is first formed, and that this undergoes isomeric change to the 2:4-acid, in consequence of the guarding influence exercised by the hetero- $\beta$ -sulphonie radicle.

The results obtained in the case of the Dahl No. 11. acid are of special interest, as one of the sulphy-groups is in the  $\beta$ -position alternative to that occupied in the acid which yields naphthol-yellow S; it is, hence, possible that, in the first instance, naphthionie acid yields a peri-disulphonie acid, and not the Schöllkopf acid.

The solution of these various problems will necessitate much further study; but obviously their settlement is of importance in relation to the theory of the formation of substitution-derivatives generally.

#### *Note on the Action of Potash on Naphthalene-1:3-Di-sulphonic Acid.* H. E. Armstrong and W. P. Wynne.

WHEN the authors' naphthalene-meta-disulphonic acid (this Journal, 1890, 283) is fused with 3—4 times its weight of caustic potash at  $280^\circ$ — $300^\circ$  for several hours, it gives a product which consists chiefly of a trihydroxynaphthalene,  $C_{10}H_5(OH)_3$ . This crystallises from water in minute scales, from light petroleum (b. p. =  $30^\circ$ ) in small, white aggregates of no definite form, and melts at  $120^\circ$ — $121^\circ$ . It sublimes in lustrous, thin scales; is extremely soluble in ether, chloroform, carbon bisulphide, acetone, and benzene; and gives no characteristic colouration with ferric chloride. The study of the action of potash on naphthalene-meta-disulphonic acid is being continued.

#### PATENTS.

*Improvements in and Relating to Colouring Matters.* H. H. Leigh, London. From R. G. Williams, Albany, U.S.A. Eng. Pat. 4565, March 15, 1889. (Reprint.) 6d.

THIS specification has already been abstracted (see this Journal, 1889, 611). It has been reprinted in consequence of an amendment made by order of the Comptroller prior to the sealing of the patent to the effect that the patentee is "aware that it has been previously proposed to use phenols or their sulphy acids in the production of mixed azo colours."—T. A. L.

*The Production of a New Colouring Matter suitable for Dyeing and Printing Cotton without the Aid of a Mordant.* J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 13,558, August 27, 1889. 6d.

HITHERTO it was generally believed that meta substitution products of benzidine were incapable of yielding direct cotton dyestuffs. The present patent describes the preparation of colouring matters of this class which dye unmordanted cotton. The base employed is that known as *o-m*-tolidine, having the formula—

(Schultz, Ber. 17, 470; this Journal, 1884, 245). The most important dyestuff obtained from it is formed by combining its tetrazo compound with naphthionie acid. To prepare the dyestuff, 10 parts of *o-m*-tolidine sulphate are suspended in 300 litres of water and 18.5 kilos. of hydrochloric acid containing 25 per cent. of HCl and diazotised with 4.5 kilos. of sodium nitrite containing 96 per cent. of  $NaNO_2$ , the solution during the operation being kept at  $0^\circ$ . The diazo solution is then poured into 450 litres of water in which 22.5 kilos. of sodium naphthionate and 20 kilos. of sodium acetate are dissolved. After stirring for about an hour, 9 kilos. of calcined soda are added and the whole stirred for three or four days. The colouring matter is then salted out and can be purified by dissolving in water and reprecipitating with salt.—T. A. L.

#### *Production of Azo-Colouring Matters from Diary-naphthalenemono-sulphonates.* O. Murray, London.

From "The Farbwerke vormals Meister, Lucius and Brüning," Höchst-on-the-Maine, Germany. Eng. Pat. 13,710, August 30, 1889. 4d.

A PROCESS for obtaining substantive colouring matters from the dihydroxynaphthalenemono-sulphonates, the preparation of which was described in Eng. Pat. 9642 of 1889 (this Journal, 1890, 609) by combining them with the following tetrazo compounds:—Tetrazodiphenyl, tetrazoditoly, tetrazodimethoxydiphenyl, tetrazodietoxydiphenyl, tetrazostilbene, tetrazostilbene-disulphonic acid. The reaction takes place in two stages, an intermediate product containing one molecule of the tetrazo compound with one molecule of the dihydroxynaphthalene-sulphonate being first obtained. This can be then further combined with another molecule of the dihydroxynaphthalene-sulphonate or with any other combinable body such as a phenol, amine, or sulphonie acid thereof.—T. A. L.

#### V.—TEXTILES: COTTON, WOOL, SILK, Etc.

##### PATENT.

*Improvements in the Treatment of Woollen, Worsted, Buck-worsted Unions, and other Woven Fabrics.* I. Smith, Batley. Eng. Pat. 14,751, September 19, 1889. 6d.

THE object of this invention "is the superseding of crabbing and steam blowing of the above-mentioned goods, and consists in a method of imparting solidity, softness, and a permanent finish to them, and securing a preparation of evenness necessary for dyeing." The fabric is passed through an apparatus known as a "weegee," consisting of a trough or cistern with two rollers near the bottom, whilst two other rollers are so arranged above the trough that they can be made to rotate alternately in contrary directions. The trough is filled with boiling water or other boiling liquid, and the fabric is placed therein, passing over one of the upper rollers, beneath the lower ones and up to the other top roller. A backward and forward movement is given to the fabric for a suitable time, according to the nature of the fabric. The required solidity, finish, and softness are hereby better attained than by the old process.

—H. S.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*Azo-Dyestuffs which Dye on the Chrome Mordant.*  
R. Lepetit. Chem. Zeit. 14, 507—508.

SINCE the introduction into commerce of Nietzki's alizarin-yellow (nitraniline-azo-salicylic acid), which is fixed on wool by the aid of the chrome mordant, numerous experiments have been made, not only to discover similar new adjective dyestuffs, but to ascertain whether any of the known azo-dyes have this property of combining with chrome. As a consequence, it has been found that rocellin, amongst older dyes, has the power of forming a weak combination, but cloth red in its various shades, and some still newer dyes, apparently of the azo-class, manufactured by the Farbenfabr. vormals F. Bayer and Co., although capable of dyeing unmordanted wool, yield colours considerably faster to light and milling when that fibre has been previously mordanted with chrome. The shades produced, however, are the same, or nearly so, as when the mordant is absent.

Instead of mordanting with chrome and then dyeing in the way usual with these colouring matters, the author prefers to dye the wool first with the assistance of sodium sulphate and oxalic acid and then, without rinsing, to boil half an hour with 2.5—3 per cent. of potassium bichromate. The shades produced in this way are darker than when the wool is first mordanted and then dyed.—E. B.

*Bleaching Wool and Silk by Sodium Hydrosulphite.*  
G. Dommergue. Monit. Scient. 1890, 4, 684—685.

SULPHUROUS acid is commonly used for bleaching silk and wool. Its use is open to several objections, and the author recommends that sodium hydrosulphite be substituted for it, as he finds that this fulfils the purpose perfectly. It is prepared in the usual way by reducing sodium sulphite by zinc, and as the solution quickly oxidises it should be prepared only when required for immediate use. The well washed material is immersed in the solution for six hours; it must then be carefully pressed and rinsed in distilled water out of contact with the air, otherwise heating takes place and the material is damaged. If the pieces be marked (due to the double sulphite of zinc and sodium) they should be passed through a bath of dilute hydrochloric acid, and then well washed. With a tank holding 1,000 litres, 130 kilos. of wool can be treated each time, and the cost would be 1 fr. 36 c. for each 10 kilos. of wool.—A. L. S.

### PATENTS.

*Improvements in the Process of Bleaching Fibrous Material by the Aid of Electricity.* C. Kellner, Vienna, Austria. Eng. Pat. 5054, April 1, 1890. 6d.

THE fibrous material is impregnated with a solution which, when electrolysed, has the power of bleaching it. The electrodes are preferably in the form of a series of revolving rollers, which draw the fibrous material along, while at the same time they act as conductors for the current. Sometimes the fibrous material is enclosed between two layers of felt, one impregnated with the anion and the other with the cathion, the whole being drawn between the rollers. Unused chlorine is absorbed by such materials as lime, magoesia, &c., placed in the electrolyte. The top rollers are alternately positive and negative, the lower ones being, of course, of opposite polarity to those just above.—E. T.

*Improvements in the Process of and Apparatus for Bleaching Vegetable Fibres.* C. Kellner, Vienna, Austria. Eng. Pat. 5285, April 5, 1890. 8d.

THIS is a process for bleaching by the aid of electrolysis, and is based on the "discovery" that the colouring matters

to be destroyed are easily converted into compounds soluble in water by alternate treatment with chlorine (or compounds containing active chlorine) and alkalis. This action is ascribed to the fact that chlorine, before it converts the colouring matter into compounds soluble in water, forms an intermediate product which, though insoluble in water, is easily soluble in alkalis. As a consequence, by the alternate action of chlorine and alkali, the process is shortened and less chlorine is required. In carrying out the invention a chloride of an alkali is decomposed by electrolysis and the anion and cathion are caused alternately to pass through the fibrous material requiring to be bleached. Afterwards both ions are again united and conveyed back into the electrolysis apparatus. Three forms of apparatus are described for carrying out this process, for the construction of which it is necessary that the drawings accompanying the specification should be consulted.—W. E. K.

*Improvements in or Applicable to Rollers and Blocks used in Printing Wall Papers and the like.* W. H. Clegg and G. Kirby, London. Eng. Pat. 10,039, June 19, 1889. 6d.

THE purpose of this invention is to lessen the cost of producing the rollers and blocks used in printing wall papers, &c. The usual practice is to build up the pattern of metallic pins and strips and then fill in the flat surfaces with felt. By this invention a pliable medium is applied to the whole surface of the roller, of a thickness equal to the usual projection of the metallic pins, and after transferring the pattern to the roller that part of the medium is cut away where no pattern is required. Lines, dots and outlines are put in by strips and pins as usual. After the pattern is cut the medium may be hardened by suitable means. The following substances are given as suitable media: compounds of powdered cork and oxidised linseed oil, &c. (as used in the manufacture of linoleum and "Lincrusta Walton") and the substance known as "fibrous sheet." Where only a small part of the roller is used for printing the medium is affixed in sections as required.—W. E. K.

*Improvements in the Dyeing, Scouring, or like Treatment of Yarn or other Fibrous Materials, and in Apparatus therefor.* E. Maertens, Providence, Rhode Island, U.S.A. Eng. Pat. 10,360, June 25, 1889. 1s. 5d.

"YARN wound into cops or balls, or on spools or bobbins, yarns in the skein or chain, combed tops, cardings, and even raw material, and certain cloths" are treated in an apparatus, which is fully described and sketched in the original specification, "the form, shape, and size of the receptacle for holding the materials to be treated being adapted to the form, shape, and bulk of such materials." Perforated cop tubes are used or unperforated tubes covered, previously to winding the yarn thereon, by loosely braided or woven tubes; in the latter case the ordinary paper cop tubes of the spinner may be employed.—E. B.

*Improvements in Indigo Printing.* J. V. Hulme, Manchester, and J. A. Walton, London. Eng. Pat. 10,635, July 1, 1889. 4d.

INDIGO, finely ground, is thoroughly reduced by means of caustic soda and zinc powder and the mixture thickened with gum. (The use of bisulphite of soda in addition is described in the provisional, but omitted from the final specification.) The mixture is printed on unprepared cloth, run over rollers in air to partially oxidise the indigo, then through a water spray, and finally through water boxes. It is afterwards soured, soaped, washed, and dried.

—W. E. K.

*Improvements in the Manufacture of Tannin Compounds, more especially intended for Printing Purposes.* B. Willeox, London. From "The Farbenfabriken vorm. F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 10,993, July 8, 1889. 4d.

By heating tannic acid with glycerin or grape sugar to 140° to 160° C. combinations are formed which are readily soluble in water and dilute acetic acid, and which possess the property of being decomposed into their constituent parts during the process of steaming to which textile prints are subjected. These products are introduced under the names of "tannin-glycoside" and "tannin-glyceride," as substitutes for the tannic acid used for the fixation of basic colouring matters in calico printing; it being claimed that the tannin is brought into action in a nascent condition during the steaming process.—W. E. K.

*Improvements in and connected with Apparatus for Dyeing, Washing, and otherwise similarly Treating Yarn in Hanks.* T. O. Arnfield, New Mills. Eng. Pat. 11,098, July 10, 1889. 8d.

This invention relates to that type of apparatus in which a concentric series of tanks have rotating above them a concentric series of pairs of rollers from which the hanks are suspended. The purpose of the invention is to provide facilities (a) for raising the hanks out of the liquors to facilitate their removal and replacement, and (b) for raising the hanks over the edges of the divisions which separate the several vats. To effect the former purpose the top roller of each pair is hung from a lever which has mounted on one end an anti-friction roller arranged to run on a circular track. At the necessary points on this track are double inclined planes, connected by a level higher platform; the motion of the roller up and down the planes produces the required lift and fall in the rollers carrying the hanks, whilst on stopping the machine when the rollers are on the higher platform the removal and replacement of the hanks is readily effected. To ensure the necessary lift from vat to vat of the bottom winches round which the yarn passes, these are connected by a lever to a stud fixed on the revolving frame. This lever is guided by a path formed on the inner edge of the vat, and by a ramp or lift in the path at the necessary points the lower end of the lever and with it the winches are lifted over the divisions which separate the vats. The invention also includes an automatic guard which prevents the yarns running off the bottom rollers.—W. E. K.

*Improvements in Machinery for the Continuous Bleaching, Soaping, Blueing, Washing, Finishing, Sizing, Dyeing, or otherwise analogously Treating in the Hank, of Cotton, Linen, Woollen, Silk, or other Yarns, Tapes, and similar Manufactures.* G. B. Sharples, Manchester. Eng. Pat. 11,382, July 16, 1889. 6d.

THREE rollers are placed parallel to each other at a suitable height above a tank or series of tanks. Two of the rollers are fixed a little distance apart and revolve in the same direction, the other being sustained and revolved by them. The latter roller has one end cone-shaped to facilitate the passing of the hanks on to it, the hanks, as the roller rotates, being carried by traverse hooks to the other end of the roller and then taken off.—E. B.

*Improvements in and relating to Machinery for Printing partially in Colours.* A. Fayol, Bordeaux. Eng. Pat. 12,896, August 15, 1889. 11d.

THE purpose of this invention is to print newspapers, &c. in part in coloured ink, with the view of enhancing the money value of the advertisements so printed. For the mechanical means by which this is effected, in the case both of the flat and of the rotary press, the specification and accompanying 25 drawings must be consulted.—W. E. K.

*A New Liquid or Solid Product applicable for Removing Grease from, Washing, Lixiviating, and Bleaching all Textile Materials, Cloths, Rags, and similar Materials, for the Fulling of Cloths, and for removing Hair from Skins and similar Operations.* J. L. Moret, Paris, France. Eng. Pat. 13,023, August 17, 1889. 6d.

THE product claimed is a mixture of caustic soda and hydrosulphide of soda (NaHS) in equal proportions. The caustic soda may be replaced by carbonate containing a certain proportion of caustic soda, and the hydrosulphide by monosulphide of sodium prepared by dry means. The material to be treated is subjected to a cold or hot bath containing the dissolved substance. If it is desired to increase the bleaching efficiency of the bath, a small quantity of sulphurous acid is added; or the material may be subsequently passed into a second bath of water acidulated with sulphurous acid.—W. E. K.

*Improved Process of applying Luminous Preparation to the Surface of Paper or other Substances.* J. A. Causton and J. Challis, London. Eng. Pat. 14,508, September 14, 1889. 4d.

To produce luminous designs the pattern is printed in any suitable way with an adhesive composition, and the luminous powder dusted or flocked over it whilst still wet or tacky. To obtain a greater body of luminous powder, a portion may also be mixed with the mucilage used in printing the design.—W. E. K.

## VII.—ACIDS, ALKALIS, AND SALTS.

*On some New Double Chromates.* M. Lachaud and C. Lepierre. *Compt. Rend.* **110**, 1035-1038.

By fusing potassium nitrate with lead chromate the authors have obtained three compounds, *i.e.*, a brick-red body insoluble in water and decomposed by dilute acid, having a composition agreeing with the formula  $\text{CrO}_4\text{Pb} \cdot \text{PbO}$ ; a yellow body,  $\text{PbCrO}_4 \cdot \text{K}_2\text{CrO}_4$ , and an orange body  $\text{PbCrO}_4 \cdot \text{K}_2\text{CrO}_4 \cdot 2\text{PbO}$ . In the same way, substituting sodium nitrate for potassium nitrate, they have obtained  $\text{PbCrO}_4 \cdot \text{Na}_2\text{CrO}_4$ , a yellow body soluble in water, and  $\text{PbCrO}_4 \cdot \text{Na}_2\text{CrO}_4 \cdot 2\text{PbO}$ , an orange body. By using lithium nitrate they have obtained  $\text{PbCrO}_4 \cdot \text{Li}_2\text{CrO}_4$ . A better yield of the double chromate is obtained by fusing with the alkaline nitrate and lead chromate some alkaline chromate. —A. L. S.

## PATENT.

*Process for the Production of Solutions of the Chlorides of Nickel and Cobalt and other Metals from the Ores or Products containing these Metals.* W. L. Wise, London. From B. Natuseh, Niederlosnitz, Germany. Eng. Pat. 19,334, December 2, 1889. 4d.

THE object of the invention is the production of a pure solution of nickel or cobalt direct from substances containing one or both of these metals. For this purpose the substance, after roasting, is chloridised at a red heat by means of chloride of iron, and the resulting product lixiviated with water. The reactions which take place in the case of cobalt are as follows:—

and—

When a solution obtained by treating a test portion of the roasted mass with water ceases to contain any more iron, the roasting process is finished. The product is

drawn into pans that can be of iron, and treated with water. In order to ensure that the metals present shall be obtained with a minimum amount of loss in one treatment, it is necessary that, as soon as the mixture is at a glowing or red heat throughout, there should be still some undecomposed ferrous chloride present, because the reaction is not completely effected until this temperature is reached.

With a roasted ore containing 10 per cent. of cobalt, 5 per cent. of nickel, and 5 per cent. of copper, an addition of about 20 per cent. of ferrous chloride will be found sufficient to ensure complete decomposition. A charge of about 200 kilos. of such a mixture will require to be roasted for one hour. In addition to cobalt and nickel there will be found, in solution, gold, silver, zinc, and copper, pure iron oxide remaining as residue.—J. B. C.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

*Contribution to the Knowledge of Felspar Porcelain.* E. Hussak. *Sprechsaal*, 22, 154, 136.

IN continuation of Bünnz's investigations (*Sprechsaal*, 1876, 39—45) the author has microscopically examined some of the materials used in the manufacture of porcelain, and this product in various stages of formation. Kaolinite from Nationale Belle mine, Denver, Colorado, is a nacreous powder consisting of microscopical well-developed hexagonal plates belonging to the monoclinic or to the triclinic system. Levigated China clay is a mass of almost pure kaolinite, the plates have, however, a rounded or irregular outline. Saxony clay contains extremely minute scales, which appear bluish-grey by polarised light and are thickly studded with grains of ferric hydrate. It is very rich in accessory minerals as quartz, zircon, rutile, and occasional scales of mica. No opal was found in any of the above products nor in the kaolins of Cornwall, Linnoges, or Türkismühle.

The author has also repeated some of Fouque and Lévy's experiments on the synthetic formation of minerals. Orthoclase was converted into microcline by melting it to a clear glass, allowing it to solidify, and heating for 24 hours at a temperature close to the melting-point. Hornblende is changed by similar treatment into augite. In the manufacture of porcelain, the orthoclase cannot crystallise out, because the temperature of fusion is too high and the cooling is too rapid. In no case was any decomposition of the orthoclase effected by fusion; the view that fusion is attended with a loss of alkali is therefore very improbable. If glasses be regarded as supersaturated solutions of salts, it is evident that felspar glass must be capable of taking up a certain amount of silica or silicate. This assumption is confirmed by the examination of specimens of porcelain in different stages of baking. In the first stage no glass is yet formed, kaolinite, felspar, and quartz lie side by side; the second stage shows the commencement and progress of vitrification, the gradual disappearance of the felspar, and an increase in the number of pores, but much quartz is still present. At the third stage (samples 4, 5, and 6) much amorphous devitrified glass and a little clear glass is present, the quartz decreases, and the pores are fewer but larger. Sample 6, when completely baked, contained relatively few large quartz fragments, the amorphous mass predominating; the outlines of the fragments of felspar were not so clear as in the other samples. The vitreous mass is permeated by a thick felt-like mass of thin doubly refracting needles resembling sillimanite,  $Al_2SiO_5$ .

The retention of their outlines by the fragments of felspar is noteworthy.—S. B. A. A.

*New Varieties of Porcelain.* Annales Industrielles, 1889, 146.

Messrs. Parvillée have composed a new paste for the porcelain-facing of bricks and wall tiles; they have a better appearance than the ordinary enamelled tiles, and it is claimed they are more durable, since they are impervious to water. The cost is only about one-fourth greater.

Lauth's new Sèvres porcelain is a soft variety resembling Chinese porcelain; it is fired at a low temperature and admits of a variety of underglaze colours being applied. It has the following composition: silica, 64.3 or 71 per cent., alumina, 28.92 or 23 per cent., potash and soda, 7.05 or 6 per cent.

The glaze used has the composition: silica, 66.56 per cent.;  $Al_2O_3 \cdot CaO$ , 14.23 per cent.; potash and soda, 3.59 per cent. The new porcelain is baked at  $1,350^\circ$ , whereas the old variety fritted at  $1,500^\circ$ .

T. Deck has prepared a new paste suitable for moulding (not casting) very large vases, &c. It consists of a real felspar body with a considerable addition of fine sand. The reliefs are fixed on the vessel after shaping. The glaze is sprinkled on.

A new soft-body porcelain has been introduced at Sèvres by Deck (compare this Journal, 1889, 983—984). The new body possesses the same translucency and takes the same glaze and colours as the ancient soft Sèvres porcelain, the former is, however, more easily shaped and may be fired without much difficulty.—S. B. A. A.

*Classification of Earthenware.* Hartig. *Thonindustrie Zeitung*, 12, 120—646.

THE author proposes a system of classifying earthenware goods according as they are glazed, unglazed, or enamelled, and according as the freshly broken surface is white or coloured, and porous or impervious to a drop of water. By this means earthenware goods may be very sharply divided into nine classes. The porosity is ascertained by comparison with a piece of dense porcelain.—S. B. A. A.

*The Action of the Sulphur in Coal on Earthenware.* *Thonindustrie Zeitung*, 14, 59 and 74.

THE author attributes the inferiority of modern to ancient German brick buildings to the use of coal as a fuel in firing the bricks.

The sulphur contained as iron pyrites, &c. in the coal is oxidised and taken up by the bases in the bricks with the formation of sulphate (compare this Journal, 1889, 983). If the bricks contain much calcium or magnesium carbonates this action may go on to a very large extent and the surface may absorb as much as 10 per cent. of sulphuric acid. A portion of the acid separates out again when the tile is heated in a reducing atmosphere, but in most modern kilns an oxidising atmosphere is constantly maintained. These sulphates disintegrate the brick by a mechanical action similar to that of water upon rocks, they deliquesce in damp weather, and on drying they form groups of crystals which press upon the adjoining particles of the brick. When these sulphates are present in any quantity, as frequently happens, they form efflorescences, and are often mistaken for nitrates of calcium, &c.

Clays in which the proportion of lime to ferric oxide is large do not burn reddish or yellowish-brown, but acquire a light red or yellowish-grey colour owing to the formation of a silicate of iron alumina and lime; when, however, the lime is combined with an acid which is not decomposed by silica at the temperature of firing, only a ferric aluminium silicate is formed; such bricks are reddish-brown on the surface, and preserve their normal colour in the interior. The yellow colour may be restored to the exterior by reheating in a reducing atmosphere. No discolouration of this kind can of course occur with wood firing. Glazed facing tiles are subject to the same danger of disruption by the sulphates, as the firing and glazing is conducted in an oxidising atmosphere obtained from coal.—S. B. A. A.

*Modern Majolica.* Henhart. Deutsche Bauzeitung, 1889, 39.

THE author distinguishes three varieties of majolica ware according to the fusibility of the coloured glazes. The first class of glaze is fired at the temperature of a gold lustre; the mixture used in English relief glazing and Linke's glaze are of this character; the want of durability ascribed to it by Krell may be obviated by selecting a glaze adapted to the body, and by sufficient firing.

The second class of glaze is fired at an incipient white heat and is very durable. The third class of glaze is used by various French manufacturers at the temperatures employed for fine earthenware; it is very durable and either underglaze or overglaze colours may be applied: the latter method is adopted by Deck with excellent results.

English productions are especially censured by the author on account of the frequent crazing, a defect easily avoided with the fine clays in use here.—S. B. A. A.

#### PATENTS.

*Improvements in the Manufacture of Terra Cotta or Porcelain Castor Bows, Knobs, and Handles.* F. C. Clare, Steehford. Eng. Pat. 9841, June 15, 1889. 4d.

A NON-VITREOUS glaze, in the form of any varnish, japan, gum, or lacquer, is used instead of the more costly vitreous glaze commonly applied.—E. G. C.

*Improvements Relating to the Enamelling of Articles of Copper.* H. H. Lake, London. From A. Gilbert, Laeken, Belgium. Eng. Pat. 11,979, July 27, 1889. 4d.

COPPER cooking utensils and the like are enamelled internally with a composition consisting of 4 parts of felspar, 3 parts of flint, 5 parts of borax, and 2 parts of cryolite.—E. G. C.

*Improvements in Treating or Ornamenting Glass and Glass-ware.* M. Lugar, London. From C. Lasalle and C. Mautter, Paris, France. Eng. Pat. 13,577, August 28, 1889. 4d.

APERTURES of suitable shapes are cut or otherwise made in the articles to be treated. These are filled in with various coloured glasses or other materials, which may project beyond or be in the same plane as that of this portion of the body. To hold the inserted glass in position, cement may be used or preferably clips of metal placed around the edges of the apertures and of the pieces to be secured therein.

—S. G. R.

### IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*The Action of Alkalis, Alkaline Earths, Alkaline Silicates, and some Saline Solutions on Mica; the Formation of Sodalite, Amphigene, Orthoclase, Anorthite.* C. and G. Friedel. Compt. Rend. 110, 1170—1178.

THE authors propose making experiments to determine the action of water, containing certain alkaline salts in solution, on different rocks, the experiments being made at an elevated temperature and under such conditions as to realise most nearly the actions which occur in nature; at present the work is only partially completed.

The materials to be acted upon are heated to a temperature of 500° C. in a thick platinum-lined steel tube, two-thirds filled with solution. In this way mica and potash yielded sodium and potassium nepheline,  $2\text{SiO}_2 \cdot \text{Al}_2\text{O}_3 \cdot \left\{ \begin{smallmatrix} \text{Na} \\ \text{K} \end{smallmatrix} \right\}_2\text{O}$ ;

when sodium chloride is also present, a compound of nepheline and sodium chloride is obtained which may be represented as  $3(2\text{SiO}_2 \cdot \text{Al}_2\text{O}_3 \cdot \text{Na}_2\text{O}) \cdot 2\text{NaCl}$ . Silica, potash and mica yielded orthoclase, other proportions gave leucite,  $4\text{SiO}_2 \cdot \text{Al}_2\text{O}_3 \cdot \text{K}_2\text{O}$ . Lime and mica in the presence of calcium chloride gave anorthite.—A. L. S.

*Linoleum Flooring.* Günther. Dingl. Polyt. J. 276, 360—363.

THE author describes the arrangements for flooring with linoleum made at the Duke Ernst seminary at Gotha. Most of the floors were formed of a bed of concrete laid down on iron supports, levelled and smoothed; the linoleum was cemented on with a paste of rye flour and turpentine, a tight fit being secured by pushing the ends into a deep groove in the skirting board. The stairs were of iron covered with concrete and artificial stone; the linoleum was imbedded in the steps to preserve the edges. The author recommends that the concrete floors in similar buildings should only be roughly levelled, and a smooth surface obtained by running on a layer of thin plaster and allowing it to harden. A fireproof flooring is thus formed the cost of which is only a fraction higher than that of a stained wooden flooring. The best linoleum will last for 20 years. It soon loses its characteristic smell if well aired, and should be periodically polished with a mixture of wax and turpentine.—S. B. A. A.

#### PATENTS.

*A Composition for Arresting or Preventing Decay in Wood.* J. T. MacMahon, London. Eng. Pat. 13,203, August 21, 1889. 4d.

See under XVIII., C., page .

*An Improved Composition for use in and in connection with the Manufacture of Portland Cement.* G. Higham, Woulham. Eng. Pat. 6855, May 3, 1890. 4d.

THE patentee mixes  $2\frac{1}{2}$ —3 cwt. of chalk or limestone with 1 cwt. of mud or clay and 8—12 chaldrons of fuel such as turf, breeze, or charcoal, moulds into bricks and burns in a kiln to produce Portland cement.—B. B.

### X.—METALLURGY.

*Jüngst's Experiments on the Application of Ferro-silicon to the Manufacture of Pig Iron.* Dingl. Polyt. J. 276, 346—355.

IN consequence of the experiments of Turner (this Journal, 1886, 289 and 606), Bischof, and Gautier (this Journal, 1889, 791) on the influence of silicon on iron, the Union of German Smelters and the Prussian Minister of Public Works commissioned Jüngst to make a series of experiments to test the possibility of producing a substitute for Scotch pig by the addition of silicon to other classes of iron, and to ascertain the best proportions of ferro-silicon for economical production and the influence of impurities (S, P, Mn, &c.) in presence of silicon.

The materials employed by Jüngst in his experiments were as follows:—(a.) Three kinds of ferro-silicon containing respectively 5·3, 10·4, and 14·3 per cent. of silicon; (b.) three kinds of white iron with 0·85, 0·35, and 0·33 per cent. of silicon, 3·54, 3·41, and 0·52 per cent. of manganese, 3·93, 3·53, and 2·76 per cent. of carbon; 1·07, 1·08, and 0·91 per cent. of phosphorus; (c.) three kinds of scrap iron containing 3·38, 2·71, and 2·05 per cent. of silicon; (d.) two kinds of burnt iron; (e.) seven

varieties of grey iron containing 3.02 to 1.06 per cent. of silicon, 3.52 to 2.77 per cent. of carbon, 2.01 to 0.44 per cent. of manganese, 1.49 to 0.1 per cent. of sulphur; (f.) wrought iron scrap.

Complete analyses were made of each variety, which was then melted down separately, its influence upon various mixtures was then observed.

A comparison of the analyses of pig iron and cast iron before and after remelting shows that silicon decreases irregularly, the average loss being 17 per cent.; combined carbon decreases in proportion as silicon can act upon it; an increase was only noted when burnt iron or grey iron containing no more than 1.06 per cent. of silicon was melted; in castings of a mixture of grey pigs and scrap and burnt iron the percentage of combined carbon remained remarkably constant. The total carbon increases in almost all cases in which silicon and manganese decrease, these elements protecting the carbon from oxidation. Manganese always decreases, the average loss being 29 per cent., phosphorus only undergoes very trifling variations; sulphur generally increases, when this increase is considerable it is due to the sulphur in the fuel. The presence of 1.55–2.25 per cent. of silicon decreases the tendency of the iron to absorb gases, a small percentage of silicon on the contrary increases this tendency, a larger percentage leads to the formation of cavities.

The soundest cast iron was obtained with 2.24 per cent. of silicon, with an increase of silicon the tendency of the castings to crack on cooling is diminished, but the injurious influence of the manganese becomes more apparent. The relation between absorption and contraction renders it probable that silicon diminishes the contraction by causing the combined carbon to separate out as graphite. The small absorption and contraction of iron melted with ferro-silicon renders superfluous the use of large "gits" of metal in casting. The experiments show that castings of this class possess extraordinary strength. This is due partly to the chemical and partly to the structural changes effected by the silicon. The fracture is characteristic, a sound tough iron showing a light grey network of close meshes filled with a dark shiny mass. Jünger considers this network to be a steel iron containing 0.5 per cent. of combined carbon, and the interstitial matter to consist of graphitic and silicon compounds; the former occasion the great toughness of the metal, and the latter conduce to the great resistance to shock and to the slight tendency to absorption. A brittle hard iron exhibits a drawn-out radiating appearance, in soft weak irons the network is very coarsely meshed and discontinuous.

The maximum transverse strength does not depend upon any particular percentage of silicon. Nearly the same results were obtained from pigs containing 1.22 to 3.07 per cent. of silicon, but the best results are only obtained when the combined carbon lies between the limits 0.49 and 0.69 per cent., and the graphite between 1.49 and 2.89 per cent.; the latter element increases the malleability and the deflection. The presence of over 3 per cent. of silicon or of over 1 per cent. of manganese diminishes the transverse strength; but up to 1 per cent. of phosphorus and 0.16 per cent. of sulphur may be present without apparent injury to the quality of the metal.

The tensile and compressive strengths are affected in the same manner as the transverse strength.

The resistance to shock is extraordinarily great; a cube of 1.2 in. side was broken by 11 blows, the work done by each blow amounting to 817 foot pounds; a plate 1 metre square and 20 millim. thick was broken by 24 blows of a ram weighing 55 lb., the last blow falling 5.25 metres; these specimens contained 2.24, 2.57, and 2.09 per cent. of silicon, 2.22, 2.52, and 1.81 per cent. of graphite, and 0.45, 0.89, and 0.55 per cent. of manganese.

Whereas large castings made from mixtures of different brands of grey pig generally contain flaws, &c. and are comparatively weak, large castings (hydraulic cylinders, &c.) made from white iron and ferro-silicon generally proved absolutely flawless and of remarkable strength. The quality of the iron was evident on machining, the turnings occasionally attaining a length of 21 in.

The strength is about 50 per cent. in excess of any cast iron in use, the transverse strength averaging over 23 tons and the tensile strength over 14 tons per square inch. Jünger concludes that Turner, Ledebur, Wood, and Gantier's statements about the influence of silicon on iron are, in general, well founded, and he further draws attention to the following points: Before adding ferro-silicon to a pig iron its composition should be ascertained, and the amount of ferro-silicon added must be proportionate to the amount of combined carbon and graphite present. Ferro-silicon should never be added to grey pigs or to other iron already rich in silicon.

The strength of the iron depends as much upon its structure as upon its chemical composition. This structure is developed in grey pig by repeated remelting, but the soundness of such castings is always doubtful. As large perfectly sound castings of great strength may readily be obtained from white iron and ferro-silicon, it is both technically advantageous and economical to use this metal for purposes in which great strength and soundness are essential. The high price of ferro-silicon would, however, at present prevent its application to common castings.

The variety of ferro-silicon most advantageous for smelting purposes is that containing about 10 per cent. of silicon; the use of a much poorer variety (5 per cent. of silicon) involves the introduction into the metal of a large quantity of manganese which deteriorates the quality of the product. When a richer variety (14 per cent. silicon) is used, very little impurity is introduced, but it becomes necessary to guard against the setting up of a purely local action by thoroughly stirring the fluid metal. Care must be taken that not more than 1 per cent. of manganese or of phosphorus and not more than 0.16 per cent. of sulphur are present; particular care should be taken to avoid an excess of manganese.

Ledebur (Stahl und Eisen, 1890, 4) is of opinion that silicon only acts indirectly upon white iron by converting it into a species of grey iron which is superior to other varieties because of its greater purity.—S. B. A. A.

*The Action of Carbon Monoxide on Nickel.* L. Mond, C. Langer, and F. Quinke. Proc. Chem. Soc. 1890 (86), 112–113.

WHEN carbon monoxide is passed over finely-divided nickel, such as is obtained by reducing nickel oxide by hydrogen at about 400°, at a temperature between 350° and 450°, carbon dioxide is formed, and the nickel is gradually converted into a black, amorphous powder, consisting of carbon and nickel; the composition of this deposit varies widely with temperature and time. A small quantity of nickel can thus change a very large amount of carbon monoxide, the action being complete and rapid at first, and continuing, although at a diminishing rate, for several weeks. A product containing as much as 85 parts carbon to 15 parts nickel was obtained. Acids only partially remove the nickel; the carbon is very readily acted on by steam, carbon dioxide, and hydrogen without a trace of carbon monoxide being formed at a temperature of 350°.

On allowing the substance to cool in a current of carbon monoxide, it was noticed that the flame of a Bunsen burner into which the escaping gas was introduced became luminous, and when the tube through which the gas passed was heated, a deposit of nickel, mixed with a small quantity of carbon, was obtained. The authors were thus led to discover the existence of a volatile nickel compound.

To prepare this compound, a combustion-tube was filled with nickel oxide and this was reduced by hydrogen at about 400°; after cooling the nickel to about 100°, pure dry carbon monoxide was passed over it without further heating, and the issuing gas led through a tube placed in a freezing mixture: the major portion of the nickel compound condensed as a colourless liquid; but since the gas retained about 5 per cent., it was collected, dried and again passed over the metal. When no more liquid condensed, the nickel was again heated to about 400° in a slow current of pure carbon monoxide; it was then cooled to about 100°, and again submitted to the action of the gas.

Nickel carbonoxide thus prepared is a colourless liquid, which boils at  $43^{\circ}$  under 751 mm. pressure; its relative density at  $17^{\circ}$  is 1.3185. It solidifies at  $-25^{\circ}$  to a mass of needle-shaped crystals. Its composition is represented by the formula  $\text{Ni}(\text{CO})_4$ . It dissolves in alcohol, and more readily in benzene and chloroform; dilute acids and alkalis have no action on it, but it is oxidised by concentrated nitric acid. It reduces an ammoniacal solution of cupric chloride, and also causes the separation of silver from an ammoniacal solution of silver chloride. It interacts with chlorine, forming nickel chloride and carbon oxychloride. It is decomposed at  $180^{\circ}$  (in boiling aniline vapour) into nickel and carbon monoxide. The atomic weight of the deposited metal was found in three experiments to be  $58.52-58.64$ , a result closely corresponding with Russell's value,  $58.74$ .

Numerous experiments to obtain similar compounds with other metals, notably with cobalt, iron, copper, and platinum, led to negative results. On experimenting with specially purified cobalt, in the beginning a slight colouration of the Bunsen flame into which the gas was led was noticed, but after a time this was no longer observed. Commercial cobalt afforded a gas which deposited a mirror of pure nickel, it being possible, in fact, to purify cobalt from nickel by carbonic oxide. The nickel mirrors obtained by heating the carbonic oxide compound do not appear to contain any trace of cobalt.

#### PATENTS.

*Improvements in Machinery and Appliances for Separating and Cleaning Auriferous and other Mineral Ores and Substances, and also Precious Stones, from their Gangue and other associated Refuse Matter.* G. M. Edwards, London. Eng. Pat. 8147, May 16, 1889. 8d.

RECTANGULAR channels with perpendicular sides are placed at an inclination of one in six between upper and lower ends. The bottoms of the channels slope at an angle of about one in four for a distance of about two feet and then rise perpendicularly to a height of about 8 in.; this arrangement being repeated to the end of each channel. Above the sloping floor are placed wedge-shaped blocks so shaped that a clear passage of about 1 in. in height is left, along which the ore and water are made to flow. Valves are placed at the end of each slope for the purpose of removing deposited matter.—H. K. T.

*Improvements in the Treatment of Waste Pickle from Galvanising Works.* T. Turner, Birmingham. Eng. Pat. 9225, June 4, 1889. 8d.

A CLOSED fire-brick furnace is used, which is heated from below, and is furnished with working doors, and with a pipe passing through the upper part of the furnace for carrying away the regenerated acid.

The bottom of the furnace is made of large fire-bricks or iron plates. The waste liquor, concentrated if necessary, is introduced from above, by allowing it to drip or trickle through pipes in the roof or sides of the furnace. The liquid is allowed to enter at such a rate, that it distils as fast as it enters, never forming more than a shallow bath of liquid, but leaving a cake of more or less basic chloride of iron, which fills up any cracks in the bottom of the furnace and protects the bottom. The cake is then broken up and heated either in the same or in another furnace to a somewhat higher temperature not exceeding a dull red heat, while air and steam are passed over in suitable proportions. The steam should be used only in such quantities as may be necessary to prevent ferric chloride distilling in the form of brown fumes with the acid (see also this Journal, 1890, 518).

—J. B. C.

*Improvements in Galvanising Iron and in Utilising the Waste Acids therefrom.* A. G. Greenway, Stafford. Eng. Pat. 9680, June 12, 1889. 4d.

THE iron to be galvanised is first treated with either hydrochloric or sulphuric acid, in order to clean the surface. A solution of ferrous chloride or sulphate is formed, which is

at first retained in a tank and then transferred to a second tank in which a solution of ammonium sulphide is added to saturation. This latter is the ordinary residual product as obtained from gas works. Ferrous sulphide is thereby precipitated, and may be separated when required. The iron, which has been cleaned as described, is immersed in a solution of ammonium chloride or sulphate in the second tank, and this may be either heated or used cold. The iron is then immersed in melted zinc and galvanised. The solution of ammonium chloride or sulphate in the second tank and the ferrous sulphide may be separated by filtration, and the solution of ammonium chloride or sulphate evaporated to form commercial salts of ammonium.—J. B. C.

*An Improved Process and Apparatus for the Amalgamation of Gold and Silver contained in their Ores.* H. Cave, London. Eng. Pat. 10,274, June 21, 1889. 8d.

THE finely pulverised ore is heated in contact with mercury vapour. It is then placed in a boat-shaped rocking vessel, together with mercury and mineral acid. When the mercury is sufficiently rich, it is squeezed in the usual way. The preliminary treatment with mercury vapour may be omitted.

—H. K. T.

*Improvements in the Treatment of Blast-Furnace Slag and other Slags, and in the Apparatus therefor.* T. Hydes, Sheffield. Eng. Pat. 10,835, July 5, 1889. 8d.

MOLTEN slag is conveyed by a conductor on to the top of a cone-shaped distributor and meets, at the edge of the latter, with an air or steam blast, or combination of both, which spreads it into a thin sheet. It then falls through zig-zag tubes surrounded by water.—H. K. T.

*Improvements in the Treatment of Blast-Furnace Slag and other Slags, and in the Apparatus used therein.* T. Hydes, Sheffield. Eng. Pat. 10,836, July 5, 1889. 6d.

THE molten slag passes between a pair of rollers, which spread it into a thin sheet. It then passes over an inclined plane, becoming cooled and brittle, and is crushed more or less to powder by a second pair of rollers. The second pair of rollers may be placed vertically below the first pair, in which case the inclined plane may be omitted. The rollers and inclined plane are hollow, and water is passed through them.—H. K. T.

*Improvements in Extracting Precious Metals from their Ores, and in Means and Apparatus employed therein.* S. Trivick, London. Eng. Pat. 11,883, July 26, 1889. 8d.

THIS is a process for leaching roasted ores to be used with the apparatus described in Eng. Pat. 11,882 of concurrent date. The ores are treated with a leaching fluid heated to  $150^{\circ}\text{F.}$  composed of sodium chloride solution of sp. gr. 1.150, to which is added one-eighth per cent. of neutral chloride of copper. The clear liquor is treated with a liquor prepared by boiling 35 lb. of lime and 18 lb. of sulphur with 100 gallons of water until a specific gravity of 1.050 is reached. Sodium chloride is then added until the specific gravity is 1.100. Sufficient of this liquor is added to precipitate the gold and silver only. The clear liquid is then drawn off and the copper in it is precipitated by a further addition of the above liquor, and is used in a fresh roasting operation. The clear liquor is then pumped into a tank to be used again for leaching. The plant consists of the following apparatus:—A roasting furnace; a chamber connected therewith, in which are coils of pipes packed in sand and supplied with water to be used for heating leaching liquor, &c.; a tank over the furnace for evaporating leaching liquor; a pan for preparing precipitating liquor; filter beds composed of basket-work and moss with canvas above and below; a mixing vessel provided with stirrers and precipitating tanks, &c., all connected by suitable pipes and valves.

—H. K. T.

*Improvements in the Manufacture of Ingot Iron and Steel.* T. Twynam, London. Eng. Pat. 12,500, August 7, 1889. 4d.

THE yield of metal for each blow when working the Bessemer process may be increased by adding to the charge iron oxide in the form of scale or ore, mixed with not less than one-fifth its weight of carbon. The mixture may be in the form of powder, but is preferably made up into bricks with tar and subjected to a preliminary coking. The iron ore, if used, should be not too siliceous, and both it and the carbonaceous matter (coal or coke) should be as free as possible from sulphur, but the presence of phosphorus is not objectionable. When a manganiferous ore is used, manganese is reduced to some extent, but is mostly re-oxidised.

The mixture is added at that stage of the blow when the silicon and about one-third of the carbon have been burnt out, or it may be charged into the converter with the lime, and the molten pig iron subsequently run in upon it.

In working charges of five tons of pig iron with 7—10 per cent. of iron scale made into bricks containing about 30 per cent. of carbon, the patentee has found that the yield of ingots has increased by fully 5 per cent., consequent on the reduction of the iron of the scale added, while the length of the after-blow has been lessened.—B. B.

*Improvements in Extracting Metals from their Ores, and Apparatus therefor.* R. Welford, Sunderland. Eng. Pat. 12,525, August 8, 1889. 8d.

THIS is an apparatus in which the filtration of the liquor, after the usual chlorination process, is carried on in the chlorinating vessel itself. It consists of a rotating barrel with hollow trunnions. One trunnion is connected with tanks supplying water and acid, and with a compressed air supply, if necessary. The other trunnion is suitably connected, on the one hand, with a filter-bed placed in the lower side of the barrel, and also with precipitating vessels, &c. Ore and chloride of lime are charged into the vessel through a hopper; the door is then closed, acid and water admitted, and the vessel rotated. After the chlorination is complete the barrel is placed so that the filter is undermost and the valve connected with the filter-bed is opened, the barrel being made to oscillate to prevent the mass "packing." When all the liquor has been drawn off the door is opened and on rotating the barrel the exhausted ore falls out.

—H. K. T.

*Improvements in or connected with the Manufacture of Iron and Steel, and in the Utilisation therefor of Waste Products.* J. C. Bromfield, Hove. Eng. Pat. 12,839, August 14, 1889. 4d.

COAL or coal-dust and the waste from tin plate works, "that is, the cuttings from the plates which are subsequently tinned and the slag from the tips," are ground together in the proportion of 1—2 tons of coal to 1 ton of waste, alumina with lime or its carbonate added if much silica be present in the waste, and the whole mixed with petroleum or other liquid fuel; 5—20 per cent. of hydraulic cement, carbonate of lime, magnesian lime, or lime are then worked in, and the material moulded into bricks or other forms. "Silica and liquid fuel may be added during the process of mixing where it is required to produce oxygen in the retort." The moulded material is coked in a retort similar to that described in Eng. Pat. 5122 of 1881, "whereby practically the whole of the sulphur and phosphorus is eliminated." (If the bricks are only to be used as a fuel in iron and steel manufacture the tin plate waste may be omitted.) The retort is made in two parts, the upper of fireclay, the lower of wrought iron, and the introduction, coking, and withdrawal of the material takes place continuously. The bricks of mixed fuel and waste, after coking, are ready to be smelted for the production of iron and steel.—B. B.

*Improvements in Refining and Separating Precious Metals.* E. Dodé, Paris, France. Eng. Pat. 14,357, September 11, 1889. 8d.

THE material, consisting of a mixture of gold, platinum, silver, copper, and tin is dissolved in aqua regia, half the acids are evaporated and water equal to three times the weight of the acids used is added. The liquid is then placed in a form of separating funnel, and ether, chloroform, or glycerins, &c., are added, using 300 grms. for every 100 grms. of metal. After all the gold is extracted the ethereal solution is drawn off, a solution of salt is added to the residue to precipitate all the silver, and the platinum is extracted from the solution by means of "essence of lavender, turpentine, or thyme" in a manner similar to that used for the gold. Finally the tin is precipitated by means of ammonia and the clear solution evaporated for the sake of the copper. The gold and platinum are obtained from their solutions by distilling the solvents.

—H. K. T.

*Process for the Production of Solutions of the Chlorides of Nickel and Cobalt and other Metals from the Ores or Products containing these Metals.* W. L. Wise, London. From B. Natuseh, Niederlosnitz, Germany. Eng. Pat. 19,334, December 2, 1889. 4d.

See under VII., page 805.

*Improvements in the Wet Method of Extracting Gold from finely divided Auriferous Quartz Ores and other auriferous Material, and in Apparatus therefor.* R. Brown and G. H. Irvine, Brisbane, Queensland. Eng. Pat. 237, January 6, 1890. 8d.

THIS invention consists in the treatment of finely divided auriferous quartz with gaseous chlorine or a solution of chlorine in water, in vacuo, and in the retention of the vacuum during chlorination. The operation is conducted in a fixed vessel provided with a stirrer or in a rotating barrel. The ore and water are first introduced, the vessel closed and exhausted and the chlorine then allowed to enter slowly, but not in sufficient quantity to entirely destroy the vacuum. The liquor is then drawn off and treated in the usual way.—H. K. T.

*An Improved Amalgamator for the Extraction of Gold and Silver from the Ore by the Action of Mercury.* C. Pfeiffer, London. Eng. Pat. 1794, February 3, 1890. 6d.

THIS apparatus consists of two cylinders, one within the other, the outer one fixed, the inner one rotating. The two cylinders communicate through a number of radial ports in the bottom of the inner cylinder. Mercury is first poured into the inner cylinder and is caused by the centrifugal force to fill the annular space between the two cylinders. The ore, mixed with water, is then poured in and under the action of centrifugal force finds its way through the mercury column.—H. K. T.

*A Method for obtaining Uniform Products from the Thomas Converter, Siemens' Open Hearth, or other Basic Furnaces.* L. Pszczolka, Graz, Austria. Eng. Pat. 3782, March 10, 1890. 4d.

"THE object of this invention is to prevent the variations arising in the quality of the metal produced from all kinds of furnaces prepared in the basic manner." "The object is attained by causing the combinations of oxides of iron, which are formed in the metal produced as aforesaid to be scorified by the addition of substances containing silicic acid ( $\text{SiO}_2$ ) instead of reducing them by carbon, manganese or silicon or like additions, by which a soft iron is made, which can never be brought to the same degree of carbonisation as the main part of the metal producing inequality or

variation in the products of basic processes especially in the harder qualities.<sup>2</sup> The metal, fined in the usual manner, is run in a liquid state into a suitable caldron previously heated or into an oxidising smelting furnace. During, before or after pouring in, there is added a considerable quantity of silica in the form of slag, glass, quartz, &c. This combines with the oxides, forming a slag. When the darkening of the slag becomes stationary the operation is complete. The quantities of silica required vary, as also the duration of the process. The metal is then recarbonised in the same vessel before casting or it is run into an ordinary pan for recarbonisation. For producing malleable iron the decarburetted and dephosphorised metal is freed from oxides according to the above described process and then cast without the addition of any recarbonising materials.—J. B. C.

*A Method for Producing Iron or Steel from Ores and other Materials containing Iron.* J. von Ehrenwerth, Austria. Eng. Pat. 4386, March 20 1890. 6d.

IRON ore and a highly carbonised iron are brought together at a high temperature. The ore is reduced at the expense of the carbon of the metal. The latter is then recarbonised by contact with carbon and a further quantity of ore is added. The operation is best conducted on the hearth of a Siemens furnace, the iron-containing materials being added in a fluid state to the metal bath. When the carbon of the latter is exhausted it is run out into a small shaft furnace containing coke or charcoal. It is then returned to the Siemens furnace and a fresh portion of ore is added. When a sufficient quantity of metal has been obtained, it is recarbonised in part or whole and cast in the usual way. Instead of working intermittently, the ore and carbon may be supplied continuously, the process only being interrupted for the removal of slag.—H. K. T.

*Improvements in Processes for obtaining Chromium and Chromium Alloys.* A. K. Eaton and K. A. Vanderbilt, Brooklyn, U.S.A. Eng. Pat. 5003, March 13, 1890. 4d.

A CHROMITE is first formed by heating together to a white heat equivalent proportions of potassium bichromate and the sulphate, preferably that of the metal whose chromite it is desired to obtain. The metals best fitted for this purpose are iron, copper, tin, and zinc. The chromite is then reduced by heating with carbon or a carbonaceous substance such as sugar, an alloy of chromium and the metal selected resulting. The latter may then be removed by a suitable solvent yielding metallic chromium. The metal best adapted for the preparation of pure chromium is zinc, which can be dissolved out from the alloy by means of nitric acid. With other metals the chromium alloys obtained are themselves valuable; thus copper and chromium give a good chromium bronze; iron and chromium yield a hard alloy capable of taking a high polish; while tin and chromium give a product which when further diluted with tin is said to resemble silver.—B. B.

*Improvements in Apparatus for the Production and Application of Gases for Metallurgical and other Purposes.* J. J. Shedlock, New Barnet, and J. J. Meldrum, Manchester. Eng. Pat. 6864, May 3, 1890. 6d.

THIS invention has for its object the economical production of a continuous supply of reducing and heating gases in which the proportions of carbonic oxide and hydrogen may be properly regulated, with special reference to the process described in Eng. Pat. 15,504 of 1884. A mixture of steam and air are forced into a large condensing chamber by means of a steam injector and after condensation of any desired proportion of the steam, the remaining gases are conveyed into a superheater, there raised to a high temperature and introduced under considerable pressure into a gas producer; the producer gas is then forced into a bath of molten metal simultaneously with the finely-divided ore under treatment; the metals in the ore are reduced and

alloy with the metal in the bath. The superheater and boiler are likewise heated by gaseous fuel from a producer supplied with air and steam by an injector or mechanical blower.—S. B. A. A.

*Improvements in and Preparation of Materials for Use in Converting Iron or Low Steel into High-grade Steel by the Cementation Process.* F. G. Bates, Philadelphia, U.S.A. Eng. Pat. 7820, May 20, 1890. 4d.

MILD steel or wrought iron is converted into high carbon steel by the cementation process, using the patentee's composition consisting of 80—100 parts of carbon and 5—10 of cryolite in the case of mild or Bessemer steel, with the addition of 10—20 parts of slaked lime for wrought iron, and 5—10 parts of rosin or carbonate of soda for malleable cast iron. After heating as in the ordinary cementation process the articles treated are preferably cooled rapidly. Metal thus prepared is capable of being hardened and tempered, and is suitable for cutting-tools; plates partially converted may be used as compound armour-plates.

Of the ingredients necessary, the cryolite may be replaced by other fluorine compounds and the slaked lime by other hydrated substances, while the carbon may be in the form of coke or charcoal; it is preferable to use the residue obtained by charring crude petroleum, by allowing it to fall in a slow stream into a heated retort; failing this, crude petroleum may be used directly as an ingredient in the cementation mixture.—B. B.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

*The Separation of Copper from Arsenic by Electrolisis.* L. W. McCay. Chem. Zeit. 14, 509.

See under XXIII., page 822.

### PATENTS.

*Improvements in the Manufacture of Elements for Voltaic Batteries.* D. G. FitzGerald, London. Eng. Pat. 4671, April 15, 1885. Amended May 24, 1890. 8d.

THIS is the amended patent for Lithanode plates. A lead oxide, such as litharge, is mixed with a salt which is decomposed by the oxide with the production of an insoluble salt of lead, so causing the whole to set. Such a salt is the sulphate of ammonia. The mixture is placed in a frame or mould and strongly compressed. A little slagwool, pumice, or such material may be added to increase the porosity. The grey plates are made preferably by pasting each face of a thin sheet of lead. The electrolyte in which the plates are formed is preferably a solution of sulphate of magnesia. The brown plates are charged and discharged several times in the above electrolyte, and then in dilute sulphuric acid for a number of times depending on their porosity. Before the electrolytic treatment, the brown plates are preferably formed superficially by the action of sodic or magnesic hypochlorite. This may be done by placing them in a tank containing hot water and some calcined magnesite; then by passing chlorine through, the magnesic hypochlorite is produced and effects the required superficial action.

In the amended specification the third claim has been erased, viz.:—"The herein described process of peroxidising plates, or masses, of lead which has been caused to 'set' as herein described, by submitting them to the oxidising action of chlorine in the presence of water, substantially as specified." (See also this Journal, 1887, 558.)—E. T.

*Improvements in Electrical Accumulators or Secondary Batteries.* F. Bosshardt, Manchester. From R. F. Verdier, Brussels, Belgium. Eng. Pat. 8973, May 30, 1889. 8d.

THE chief features of this patent are the composition of the active substance and of the electrolyte. The former is a mixture of "oxide of lead, litharge or red lead" with a vegetable siccativ oil, or glycerin and water. The plate is pasted with this mixture, and the paste is compressed and furnished with perforations. When hardened sufficiently it is put into the cell, resting on a horizontal perforated support, with a sheet of some such material as asbestos between. For forming, the electrolyte is a solution of an alkaline sulphate, but for after-use an acid electrolyte is used. The remainder of the patent refers to minor details of arrangement and construction of the electrodes.—E. T.

*Improvements in Electric Batteries.* H. H. Lake, London. From C. A. Hussey and E. H. Brown, New York, U.S.A. Eng. Pat. 10,695, July 2, 1889. 8d.

IN this two-fluid battery a horizontal porous partition is employed and the preferable mode of obtaining this horizontal arrangement is by using a porous cup-shaped vessel, the sides of which have been rendered non-porous either in the manufacture or by the application of some substance such as paraffin. The cup is also provided with lugs by means of which it can be supported by the walls of the containing vessel.

The containing vessel is made with a large spout through which the necessary materials can either be put into or withdrawn from the vessel.—B. T.

*Improvements in Electric Batteries.* H. H. Lake, London. From C. A. Hussey and E. H. Brown, New York, U.S.A. Eng. Pat. 10,696, July 2, 1889. 8d.

THE invention is an improvement in the construction of those cells employing a solution of a copper salt. The zinc is placed at the top of the cell, suspended in a porous cup but without touching it. The negative electrode is at the bottom. Below the porous cell is a perforated disc of some such metal as iron, which can decompose any of the copper salt that may diffuse upwards, before it can reach the zinc. The latter has a groove round its top surface to contain mercury.—E. T.

*Improved Apparatus for Extracting Gold and Silver from their Ores by Electrical Amalgamation.* G. Button and W. E. Wyeth, Cambridge, South Africa. Eng. Pat. 10,822, July 4, 1889. 4d.

THE ore, suspended in water, is made to travel across channels containing mercury. The channels form part of a table covered with copper. Above them are placed metallic brushes suspended so as to have a to-and-fro motion. The table is connected with the negative pole of a dynamo; the brushes with the positive pole. The ore and water are made to flow over flat plates before and after passing over the corrugated table. The plates and table are coated with gold, burnt in.—H. K. T.

*Manufacture of Elements or Plates for Secondary Batteries.* J. H. Johnson, London. From A. L. Riker, New York, U.S.A. Eng. Pat. 11,070, July 9, 1889. 8d.

IN order to retain the active material a grid or plate of lead is cast with holes of such a shape that they have a larger area on one side than on the other. These holes are then packed with the active material and the plate is folded on itself, so that the large ends of the holes are inside and the conical wedge of lead oxide cannot possibly fall out. A sheet of absorbent material, such as asbestos, may be placed in the fold in order to increase the capacity of the plate by exposing more surface to the action of the electrolyte.

—B. T.

*Improvements in and Connected with the Manufacture of Iron and Steel.* T. Parker, Wolverhampton. Eng. Pat. 11,393, July 16, 1889. 4d.

IRON is dissolved by hydrochloric or sulphuric acid, the solution neutralised by an alkali, and the liquid used as the electrolyte of a bath in which the anode is iron in the form of borings, turnings, or scrap, and the cathode, preferably iron, shaped to fit the containing vessel. With a difference of potential of 1.5—2 volts, iron is continuously dissolved from the anode and re-deposited on the cathode. The metal thus obtained is said to be free from the impurities that impair its value for making high class iron and steel.

—B. B.

*Improvements in the Formation of Electrodes for Use in Primary and Secondary Electric Batteries.* L. Epstein, Berlin, Germany. Eng. Pat. 350, January 8, 1890. 8d.

ELECTRODES of plain, grooved, or corrugated lead are boiled for some time in a weak solution of an acid or salt that has the power of dissolving lead; such, for example, as dilute nitric acid, carbonate of soda, &c. They are then dried by exposure to the air. These are then made into positives by forming in the usual way in an electrolyte of sulphuric acid, or a suitable sulphate, —a little acetic or similar acid being added. Negatives are produced from positives made as above, by a second forming process, with the current passing in the reverse direction. Such electrodes are said to have large storage capacity, rate of output, and durability, and to require very little time and no reversals for the process of formation.—E. T.

*Improvements in Electric Batteries.* H. H. Lake, London. From the Crosby Electric Company, New York, U.S.A. Eng. Pat. 3924, March 12, 1890. 6d.

IN a zinc containing-jar, preferably amalgamated, is placed a carbon pencil insulated by hard rubber rings. The space between the carbon and the zinc jar is packed with cotton waste or other spongy material prepared as follows: It is first soaked in strong sal-ammoniac and then squeezed out, the greasy matters being thereby removed; it is then once more saturated and packed between the zinc and the carbon. There should be crystals of sal-ammoniac adhering to it. Connexion is preferably made with the carbon by a cap of tin-lead alloy cast on.—E. T.

*Improvements in Secondary Voltaic Batteries.* H. T. Cheswright, Carcassonne, France. Eng. Pat. 4087, March 15, 1890. 6d.

LEAD tubing of round or other convenient section is made in the usual way except that it is furnished with longitudinal ribs as shown. Lengths of this tubing are placed horizontally one above the other, in a suitable supporting frame.

ELECTRODE FOR SECONDARY BATTERIES.

A plate is thus formed with a number of grooves on each face. Into these grooves the active material is pasted. The supporting frame has a projecting lug or bracket with a short transverse piece of tube at its end. When all the positives or negatives are placed in position, these short pieces of tube come into line so that a bolt can be put through the whole series, and by tightening the nut on this bolt the whole can be firmly bound together. The pieces of

tube are of such a length that when so tightened up the various plates will be the correct distance apart. Such electrodes are said to have great strength and yet to be very light.—E. T.

*Improvements in the Process of Bleaching Fibrous Material by the Aid of Electricity.* C. Kellner, Vienna, Austria. Eng. Pat. 5054, April 1, 1890. 6d.

See under VI., page 804.

*An Improved Insulating Compound.* H. H. Lake, London. From A. A. Kundson, Brooklyn, U.S.A. Eng. Pat. 5730, April 15, 1890. 4d.

This compound consists of about equal parts of shellac or its equivalent, and carbolic acid.—E. G. C.

*Improvements in Secondary Batteries.* G. Barker, Birmingham. From H. Woodward, Toronto, Canada. Eng. Pat. 6176, April 23, 1890. 8d.

Each electrode consists of a central lead conductor, in a perforated tube of vulcanised rubber or other suitable material, the space between being packed with filings, shavings, &c. of lead or lead alloy. These tubes are placed vertically in rows, passing at top and bottom through holes in horizontal plates of insulating material. The central conductors of similar electrodes are attached to a common cross-piece at the top of the cell. Formation is hastened by saturating the lead filings in nitric acid and straining, before filling into the tubes. It is also hastened by the addition of a small quantity of sulphate of soda or magnesia.—E. T.

*An Improved Galvanic Element with Constant Current, applicable especially for producing Incandescent Light.* J. von der Poppenburg, Berlin, Germany. Eng. Pat. 6893, May 3, 1890. 4d.

A porous material, such as chaff, wood, &c., is packed between the zinc and carbon of the cell, together with a liquid containing "vegetable ethers in aqueous solution." It is said that oxide of zinc is formed and, being retained near the surface of the zinc plate, reunites with it in the shape of "projecting points or bodies of zinc." The "ethers" also are said to have the effect of "regenerating the element when at rest."—E. T.

*Improvements in and relating to Galvanic Batteries.* A. Million and P. Bony, Lyons, France. Eng. Pat. 7444, May 13, 1890. 6d.

In a circular containing-cell are placed two co-axial porous tubes, joined together at the bottom so as to form an annular porous cell. In this is placed a cylinder of zinc, while carbon rods are placed inside the innermost cylinder, and more carbon rods outside the outer one. Each set of carbon rods has a lead cap cast on the upper ends, which are first protected by a coating of some inoxidisable material such as gold or platinum.—E. T.

*Improvements in Electric Accumulators or Secondary Batteries, and in the Manufacture and Production of Plates or Elements therefor.* J. Y. Johnson, London. From C. Hering, Paris, France. Eng. Pat. 8578, June 3, 1890. 8d.

The solid peroxide plates used in these cells are made as follows:—The oxide of lead, together with some salt of lead that contracts when converted into peroxide, such as the carbonate, is mixed into a firm paste with a solution of a soluble salt of lead such as the acetate. This is compressed into slabs, and perforated. A little peroxide is added to the other materials to increase the conductivity. The contraction of the carbonate in its conversion to peroxide in the process of formation causes the plate to become porous. The plate may be hardened by immersion in sulphuric acid,

or by the deposition upon it of peroxide of lead by electrolysis in a solution of nitrate of lead. Very porous and tenacious grey plates are produced by compression of the arborescent crystals of lead obtained by the electrolysis of a soluble lead salt such as the nitrate. The plates may be used vertically or horizontally. In the latter case, the order of arrangement is as follows:—Conducting plate of lead, active material, sheet of insulating material; conducting plate, active material usually of opposite polarity, insulating material: this order repeated as far as desired. The whole pile is then bound together between compression plates by bolts and nuts. The current enters and leaves only at the edges of the plates, and in the perforations, which all agree throughout the pile.—E. T.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

### PATENTS.

*An Improvement in the Manufacture of Soap Powder.* J. Taylor, Leith. Eng. Pat. 8567, May 23, 1889. 4d.

The patentee claims the employment of Irish moss, or a jelly made therefrom, in the manufacture of "soap powder, dry soap, or extract of soap."—O. H.

*Improvements in or appertaining to Presses for Extracting Oil or other Liquids from Seeds or the like.* W. P. Thompson, Liverpool. From A. Schumacher and Tschiffeli, Marseilles, France. Eng. Pat. 8740, May 27, 1889. 8d.

The inventors' system makes it possible to increase at will the pressure on the substance in the extraction cages without increasing the manometrical pressure of the water or other liquid injected into the cylinder. It further dispenses with the "envelopes" of hair, aloë fibre, or esparto. This apparatus enables the operator to get a very much higher proportion of oil at the first pressing, and is claimed to effect a notable economy in the amount of labour and of motive power necessary in oil mills. For details the specification must be consulted.—C. F. C.

*Improvements in Sheep Dips or Washes for Animals.* R. Angus and G. Craig, Cumnock. Eng. Pat. 13,674, August 30, 1889. 4d.

PHENOLOID or like substances are combined with caustic alkali and sulphur. By the term phenoloid the inventors designate phenol or any of its homologues; and they prefer to use "eresol, xylenol, and the like, or the varying mixtures thereof derivable from the tars produced at gas works, blast furnaces, coke ovens, and gas producers."—E. G. C.

*Improvements in Apparatus for Extracting Fatty and other Matters from Substances by means of Volatile Solvents.* H. A. A. Dombrain, Leeds, and O. Trumper, Stratford. Eng. Pat. 18,345, November 16, 1889. 8d.

The inventors' improved apparatus consists of a series of "inclined cells provided with rotating worms and communications such that the material is caused to pass up and down in a zigzag course through the successive cells, while the liquid solvent flows through them in an opposite direction." The extraction cells are combined with a still and condensers, as shown in the annexed figure.—C. F. C.

*An Improved Washing and Cleaning Composition.* J. Bowden, W. C. Penn, and E. L. Downing, Cardiff. Eng. Pat. 1741, February 1, 1890. 4d.

THE inventors claim a mixture of turpentine, peppermint, soap, petroleum, Roumanian bark, soda, water, and scent, as affording a washing composition of quite remarkable properties.—C. F. C.

*Improvements in the Manufacture of Cleansing and Polishing Materials.* J. A. Fisher and J. C. S. Melay, London. Eng. Pat. 4436, March 21, 1890. 4d.

THE patentees prepare materials for such purposes by mixing asbestos powder, soap, ground rock-crystal, and whiting, the specific claim being for the former.—C. F. C.

*Improvements in and Apparatus for the Treatment of Waste Rubber Goods, to recover the Rubber therefrom, and the Production of a New Product by such treatment.* J. Y. Johnson, London. From N. C. Mitchell, Philadelphia, U.S.A. Eng. Pat. 20,289, December 17, 1889. 2s.

THERE are 32 claims and seven sheets of drawings in this specification, which describes in detail methods for separating from the waste stock to be treated (old boots, shoes, &c.), all foreign matters, such as buckles, nails, stiffening fabrics, cotton, wool, and the like, reducing the available stock to fragments of a size convenient for further treatment, devulcanising, by preliminary admixture with calcium sulphide and petroleum, and subsequent treatment with steam under pressure, drying the product, and the production of a devulcanised rubber powder (a new commodity).—E. G. C.

*An Improved Manufacture of Anti-Corrosive Compound.* D. Fulton, Manchester. From D. F. Schmid, Baltimore, U.S.A. Eng. Pat. 5387, April 9, 1890. 4d.

THIS compound is made by mixing molten lead with cotton-seed oil, re-melting, and again mixing, until the oil has absorbed the desired quantity of lead (about 10 lb. of lead to the gallon of oil). The compound may be applied with a sponge or brush, like ordinary paint.—E. G. C.

*An Improved Insulating Compound.* H. H. Lake, London. From A. A. Knudson, Brooklyn, U.S.A. Eng. Pat. 5730, April 15, 1890.

See under XI., page 813.

### XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

#### PATENTS.

*An Improved Manufacture of Liquid Waterproof Glue.* W. G. Richardson, Bradford. Eng. Pat. 10,900, July 6, 1889. 4d.

THE components are:—Shellac, 12 lb.; naphtha (or spirit), 1 gall.; tar,  $\frac{1}{4}$  lb.; boracic acid, 1 fl. oz.; vegetable oil, 1 fl. oz.; and dye, *q.s.*—E. G. C.

*Improvements in Machinery or Apparatus for Spreading Waterproof or other Plastic Materials or Cements upon Fabrics.* H. Birley and T. Williams, Manchester. Eng. Pat. 12,060, July 30, 1889. 6d.

ACCORDING to this invention, each gauge or spreader is divided into two or more lengths, each of which is suitable for the narrow fabric upon which the plastic material is to be spread; and each line of spreaders swings or oscillates upon a spindle or arbor, passing through the whole line of spreaders, or otherwise so arranged that each length can be independently raised from the fabric in the usual way. A wide machine is thus rendered available for spreading the plastic material simultaneously on two or more narrow widths of fabric.—E. G. C.

*A New Compound to be Used in Paint or Pigment.* R. Condy, London. Eng. Pat. 12,292, August 2, 1889. 6d.

HYDRATED oxide of lead is precipitated, in conjunction with sulphate of lead, from solutions of lead salts; or it is ground and intimately mixed with sulphate of lead.—E. G. C.

*Improvements in Gutta-Percha Compounds, and the Modes and Means of Preparing or Treating the same.* R. Dick, Glasgow. Eng. Pat. 12,756, August 13, 1889. 6d.

THE inventor claims "the manufacture and use of compounds composed of raw gutta-percha, balata, or gutta-percha and balata, with raw india-rubber, either with or without a proportion of crumb or reduced vulcanised india-rubber."—E. G. C.

*Improvements in Waterproof Fabrics for Surgical or Curative Purposes.* E. G. Hughes, Manchester. Eng. Pat. 13,588, August 28, 1889. 4d.

THIS muslin or cambric is treated on both sides with a solution of pure india-rubber, the fabric being then subjected to steam vulcanisation. The product is stated to be much superior to oiled silk, &c.—E. G. C.

### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

#### PATENTS.

*Improvements in and Apparatus or Means for the Tanning of Hides, Skins, or other Leather Goods.* B. Nicholson, South Norwood, and T. Palmer, London. Eng. Pat. 9776, June 13, 1889. 8d.

THIS invention consists in improvements in rotating drums according to which means are provided within the drum for the suspension of the hides to be tanned. The hides are suspended on rods which pass through the length of the drum and through the heads thereof, the points of contact between the rods and the heads of the drum being insulated. Currents of electricity are passed through these rods and thus through the hides, and the electrical connexions are so arranged that the current passes through the rods only when they are not immersed in the tan liquor. It is preferred that the hides should represent the positive pole and the tan liquor the negative. A drawing is given, and for further particulars the specification must be consulted.—B. H.

*A New Liquid or Solid Product applicable for Removing Grease from Washing, Lixiviating and Bleaching all Textile Materials, for the Felling of Cloths, and for Removing Hair from Skins, and similar Operations.* J. L. Moret, Paris, France. Eng. Pat. 13,023, Aug. 17, 1889. 6d.

See under VI., page 805.

*An Improved Shoemaker's Cement.* J. Saunders, London. Eng. Pat. 1727, February 1, 1890. 4d.

This cement is to be used for attaching leather or dermatine soles to boots and shoes, for splices, and for belts of every description. The cement is prepared by mixing together the following five ingredients in the proportions given: Methylated ether, 1 lb.; carbon bisulphide, 8 lb.; raw gutta-percha, 1 oz.; elastic glue, 1 oz.; india-rubber tissue, 1 lb. The mixture is left for 12 hours, and after being agitated for one hour is fit for use. The mode of application is to roughen the surfaces of the articles to be united, to apply one or two coats of the cement, allow to dry, warm gently, press both articles firmly together, and tap with a hammer.—B. H.

*Improvements in Machinery for Dressing Skins or Hides.* C. A. Brown, Exeter. Eng. Pat. 6115, April 22, 1890. 6d.

This invention relates to an improved mode of mounting the tools used in striking, scouring, and fleshing skins or hides, by means of which the tools shall bear evenly throughout their traverse on the skins or leather. In operating upon the skin it is usual to have a double set of tool holders and to work the tools in opposite directions from the centre to the opposite edges of the skin, and a description, with drawing, is given of the means employed for raising, depressing, and traversing the tool holders in opposite directions over the work, and for maintaining their parallelism with the work while their respective sets of tools are in action.—B. H.

## XVI.—SUGAR, STARCH, GUM, Etc.

*Further Contributions to a Knowledge of Melitriose and Melibiose.* C. Scheibler and H. Mittelmeier. Ber. 23, 1438—1443.

In a previous contribution (Ber. 22, 1678; this Journal, 1889, 718) the authors have described some of the properties of melibiose, a disaccharide which they obtained by the limited inversion of melitriose (raffinose). They have not yet succeeded in crystallising it. A combustion of the sugar gave numbers pointing to the formula  $C_{12}H_{22}O_{11}$ . Two determinations of the specific rotatory power gave  $[\alpha]_D = 126.7^\circ$  and  $[\alpha]_D = 127.9^\circ$ .

Melibiosephenylhydrazine was prepared by dissolving as much phenylhydrazine as possible in a thick syrup of the sugar. After standing some days, the syrup was dissolved in alcohol, and the compound precipitated by ether and crystallised from hot alcohol. Its formula is  $C_{13}H_{23}O_{10}N$ . It is insoluble in ether, benzene, chloroform, easily soluble in water, and difficultly in alcohol. It melts at about  $145^\circ$ . Its aqueous solution, heated with phenylhydrazine acetate, yields phenylmelibiosazon.

Oetaacetylmelibiose,  $C_{12}H_{14}O_{11}(C_2H_3O)_8$  is prepared by heating the dry sugar with acetic anhydride and sodium acetate. It crystallises from hot alcohol in large well-formed needles, radiating from a common centre. It melts at  $170^\circ$ — $171^\circ$ ; this is rather noteworthy, as the oetaacetyl compound of lactose, which melibiose closely resembles, melts at  $86^\circ$ . It is almost insoluble in cold water, rather more soluble in hot water, from which it crystallises on cooling. It is easily soluble in chloroform, also in hot alcohol, in glacial acetic acid, and benzene, less easily in ether and difficultly in carbon disulphide and petroleum spirit. Dissolved in a mixture of alcohol and chloroform its specific rotatory power was  $[\alpha]_D = 94.2$ . It reduces Fehling's solution, and is without action on phenylhydrazine, just as with the pentaacetyl compounds of dextrose, galactose, and levulose.

In order to throw further light on the constitution of melitriose, an acetyl derivative was prepared in the usual way; its composition was found to be  $C_{13}H_{20}O_{10}(C_2H_3O)_8$ . This compound does not reduce Fehling's solution, it is easily soluble in cold absolute alcohol and very easily in hot, and separates out on cooling as an amorphous mass. It behaves in the same way with ether. It is also soluble in

phenylhydrazine, aniline, chloroform, benzene, glacial acetic acid, and slightly in carbon disulphide and petroleum ether. From all the solutions it separates in the amorphous state. It melts at  $99^\circ$ — $101^\circ C.$ , and in alcoholic solution its specific rotatory power is  $[\alpha]_D = 92.2^\circ$ .—A. L. S.

*Extraction of Raffinose from Molasses.* L. Lindet. Bull. Soc. Chim. 1890, 682—685.

THE methods proposed by Scheibler (this Journal, 1885, 607), Lippmann (this Journal, 1885, 356), and Pellett (Jour. fab. Sucre, 1885, 22) have the common defect of treating the molasses without previous clarification. Treatment with subacetate of lead (as in Lippmann and Pellett's methods) is useless since the acetic acid left after precipitating the lead would invert the sugars during the evaporation of the liquors. The author proceeds as follows:—The molasses diluted with 5 or 6 parts of water is agitated in the cold with about 5 per cent. by weight of mercuric sulphate, filtered, the sulphuric acid precipitated with baryta water, and the slightly alkaline liquor boiled for some time to remove the last traces of mercury as basic salt, concentrated to a syrupy consistency in a vacuum and taken up with concentrated methyl alcohol. The solution, which is only slightly coloured, contains the sugars, the separation of which depends upon the following differences of solubility:—

100 cc. of the Solvent take up Grms. of	Methyl Alcohol.	Ethyl Alcohol.			
	Anhydrous.	$95^\circ$	$90^\circ$	$85^\circ$	$80^\circ$
Saccharose.....	0.4	0.30	1.00	2.23	6.20
Raffinose .....	9.5	0.06	0.08	0.10	0.21

The solution is heated in a flask connected by a worm with a second flask filled with quicklime and attached to a condensing apparatus leading back into the first flask. Both flasks are heated on the water-bath, and whilst both alcoholic and aqueous vapours pass into the quicklime only anhydrous alcohol is returned, the solution is thus gradually dehydrated and the saccharose deposited. As complete dehydration is impossible on account of the energy with which the sugars retain water, the mother-liquor is treated with ethyl alcohol, and the syrupy precipitate of the mixed sugars crystallised from alcohol of  $80^\circ$ — $85^\circ$ . The whole of the saccharose may in this way easily be left in solution.

The manner in which the presence of either of these sugars increases the solubility of the other, and the modification of the crystalline form of saccharose effected by a small quantity of raffinose renders the existence of some compound of the two sugars very probable.—S. B. A. A.

*On the Products of the Saccharification of Starchy Materials by Acids.* G. Flourens. Compt. Rend. 110, 1204—1206.

THE author has examined the products formed at different stages of the saccharification of starch by dilute acids, and finds that their cupric reducing power and optical activity agree with the supposition that only dextrose and dextrin and no maltose are formed.—A. L. S.

## PATENT.

*Improvements in Multiple-Effect Evaporating Apparatus for Evaporating or Concentrating Sugar Juice and other Liquids.* W. Maxwell, Djoeja, Java. Eng. Pat. 12,809, August 14, 1889. 8d.

See under 1., page 794.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*On the Bouquet of Wines and Spirits.* A. Rommier.  
Compt. Rend. 110, 1039—1041.

THE author has previously shown (Compt. Rend. 99, 879; this Journal, 1885, 462) that if ellipsoidal yeast be added to pressed grapes at a temperature below  $21^{\circ}$ — $22^{\circ}$  C., it plays the chief part in the subsequent fermentation to the exclusion of the natural yeast, but if the temperature be above  $21^{\circ}$ — $22^{\circ}$  the ellipsoidal and natural yeast develop side by side, the artificially introduced yeast still modifying the character of the wine.

Martinand (Bull. de l'Assoc. des Chimistes de sucrerie et de distillerie, 1889, 184) has sterilised grapes by immersion in 5 per cent. bisulphite of soda and after washing pressed them in the usual way and fermented the juice with yeast from (1) spontaneously fermenting cherries, (2) wine of Beaujolais, (3) Burgundy, (4) Champagne, (5) Bordeaux. The wine from each fermentation had a different flavour. The author has made similar experiments to determine if these differences of flavour extend also to the spirits distilled from these wines. A solution of cane sugar with suitable yeast food was fermented with yeast from different vineyards. The alcohols obtained by distillation had all a different character.—A. L. S.

*Invertase: a Contribution to the History of an Enzyme or Unorganised Ferment.* C. O'Sullivan and F. W. Thompson.  
Proc. Chem. Soc. 1890 (86), 107—112.

THE substance present in yeast, &c., known as *invertase*, which possesses the power, under suitable conditions, of inducing the hydrolysis of cane-sugar, has been studied by the authors with the object of determining the precise manner in which it acts, and its constitution.

The method adopted in determining the functions of invertase is essentially that developed by Vernon Harcourt in his paper "On the observation of the course of chemical change." A solution of cane-sugar was mixed with a measured amount of invertase, and the action was allowed to take place at a known temperature during a definite time; action was then stopped by the addition of alkali, and its extent determined.

The authors arrived at the following conclusions:—

1. The rate of hydrolysis of cane-sugar by means of invertase may always be expressed by a definite time-curve; this curve is practically that given by Harcourt as expressing a chemical change "of which no condition varies excepting the diminution of the changing substance." There are, however, some slight and apparently constant deviations from the theoretical curve.

2. Whatever the conditions may be under which hydrolysis is taking place, as long as these conditions remain unchanged, this curve is adhered to.

3. When the degree of acidity is that most favourable for the action of invertase, the rapidity of the action is in proportion to the amount of invertase present.

4. The most favourable concentration of the sugar solution at a temperature of  $54^{\circ}$  C. is about 20 per cent. Below that there is a rapid decline in the speed of hydrolysis. Greater concentrations are only slightly less favourable until about 40 grms. per 100 cc. is reached. In saturated solutions hydrolysis only proceeds with extreme slowness.

5. The speed of hydrolysis increases rapidly with the temperature until  $55^{\circ}$ — $60^{\circ}$  C. is reached. At  $65^{\circ}$  C. the invertase is slowly destroyed, and at  $75^{\circ}$  C. it is immediately destroyed. At the lower temperatures the speed of the action increases with rise of temperature in accordance with Harcourt's law: the rate being about doubled for  $10^{\circ}$  rise; but above  $30^{\circ}$  C. the increase is not nearly so rapid.

6. Elevated temperatures have no permanent effect on the activity of the invertase so long as they are not sufficiently high to destroy it.

7. The caustic alkalis, even in very small proportions, are instantly and irretrievably destructive of invertase.

8. Minute quantities of sulphuric acid are exceedingly favourable to the action, but a slight increase of acidity

beyond the most favourable point is very detrimental. The most favourable amount of acid increases to some extent with the proportion of invertase, and decreases with rise of temperature, but the authors have not been able to discover on what it depends.

9. In studying the action of invertase it is of the utmost importance that the most favourable amount of acid should be employed; otherwise correct results cannot be obtained. At a temperature of  $60^{\circ}$  C. the action is almost stopped unless exactly the right amount of acid is used, whilst if this factor is properly adjusted hydrolysis proceeds at (probably) the maximum speed.

10. The influence of alcohol varies in direct proportion with the amount present. Five per cent. of alcohol decreases the speed of the action by about one-half.

11. The dextrose formed by the action of invertase is initially in the birotatory state.

12. The optical activity of a solution undergoing hydrolysis is no guide to the amount of hydrolysis that has taken place.

13. If a caustic alkali be added to a solution undergoing hydrolysis, and the optical activity be allowed sufficient time to become constant, it is a true indicator of the amount of inversion that had taken place at the moment of adding the alkali.

14. A sample of invertase which had induced hydrolysis of 100,000 times its own weight of cane-sugar was still active.

15. Invertase itself is not injured or destroyed during its action on cane-sugar.

16. There is no limit to the amount of sugar which can be hydrolysed with the aid of invertase.

17. The hydrolysis of cane-sugar by means of invertase is a simple chemical change differing in no important way from those which inorganic substances undergo.

18. The products of hydrolysis have no influence on the rate of the action.

19. A solution of invertase will withstand a temperature  $25^{\circ}$  C. higher in the presence of cane-sugar than in its absence.

20. The authors are of opinion that when invertase inverts cane-sugar, combination takes place between the two substances, and that the invertase remains in combination with the invert-sugar. This combination breaks up in the presence of molecules of cane-sugar.

21. A means of estimating the activity of a material containing invertase has been devised, which consists in recording the result by means of the time factor  $\pm 0 = x$  min. In this equation  $\pm 0 =$  a certain definite amount of work and  $x =$  the time necessary to perform it. The expression means that the given inverting material takes  $x$  minutes to invert a standard amount of cane-sugar under standard conditions. The number  $x$  varies in inverse proportion to the actual amount of invertase contained in the material or materials under examination.

22. If sound brewers' yeast be pressed and then kept at the ordinary temperature for a month or two, it does not undergo putrefaction, but changes into a heavy yellow liquid; the product possesses no power of fermentation, but an apparent increase takes place in the invertive power.

23. From such liquefied yeast it is easy to filter off a bright solution of high hydrolytic power. It is shown that all the invertase of the yeast is in this solution, which is termed yeast liquor.

24. Yeast liquor has a relative density of about 1080. It will remain for a long time unaltered, excepting that the colour darkens. If exposed to the air it may slowly become covered with mould.

25. If spirit be added to yeast liquor until the mixture contains 47 per cent. of alcohol, the whole of the invertase separates with only a slight loss of power. This precipitated invertase may be washed with spirit of the same strength and then the residue either dehydrated with strong alcohol and dried *in vacuo*, or else it may be extracted by means of 10 to 20 per cent. alcohol and then filtered. The filtrate contains the invertase. On one occasion the extent of the loss involved by this process was determined, and it was found that all the invertase of the yeast liquor was present in the filtrate except 12.3 per cent.

26. The authors have not succeeded in further purifying invertase preparations carefully made in this manner. The slightest attempt at purification destroys the invertase.

27. They have prepared invertase almost free from ash.

28. The inverting power of pressed English yeast varies from  $0 = 1000''$  to  $\pm 0 = \pm 3000''$ , or about one-third of these amounts if calculated on the dry solid matter of the yeast.

29. The inverting power of the most active invertase preparation made was  $\pm 0 = 25 \cdot 1$  on the dry solid matter. It is believed that pure invertase would approximately have  $\pm 0 = 22 \cdot 5$  min.

30. The dry solid matter of yeast contains from 2 to 6 per cent. of invertase. 5·8 per cent. of invertase was separated from one sample of yeast.

31. During the preparation of invertase from yeast liquor an albuminoid is obtained, which is not redissolved by water. This is termed yeast albuminoid.

32. Invertase, when it approaches a pure state, is a very unstable substance. The products of its decomposition have been carefully examined and are found to constitute a new series of substances belonging to the *invertan* series.

33. The invertan series is a homologous series of substances which on analysis yield numbers which may be expressed in terms of an albuminoid and a carbohydrate. Seven members of the series are described.

34. The authors consider that invertase itself is a member of the invertan series, and they call it  $\beta$ -invertan.

35. If the products of the decomposition of  $\beta$ -invertan are examined, it is usually found that they consist of  $\alpha$ - and  $\delta$ -invertan. The former contains more, and the latter less, nitrogen than invertase.

36.  $\alpha$ -Invertan is insoluble in water, and in all its other properties seems to resemble yeast albuminoid. It contains 8·35 per cent. N. It is a very stable substance.

37.  $\beta$ -Invertan or invertase is soluble in water, and is the only member of the series which has the power of inverting cane-sugar. It contains about 3·69 per cent. N., and its optical activity is  $[\alpha]_D = + 80^\circ (?)$ .

38.  $\gamma$ - and  $\delta$ -invertan are the products of the simplification of invertase. One or other of these two substances seems invariably to be formed. They both contain less nitrogen than invertase, and are always accompanied by  $\alpha$ -invertan. Both are readily soluble in water. They contain respectively 3·15 and 2·43 per cent. N., and their optical activity is  $[\alpha]_D = + 45^\circ$  and  $+ 54^\circ$ .

39.  $\epsilon$ -Invertan is formed from the slow breaking down of  $\delta$ -invertan. At the same time an insoluble substance, resembling  $\alpha$ -invertan, is formed. This probably consists of another member of the series coming between  $\alpha$ - and  $\beta$ -invertan.  $\epsilon$ -Invertan is soluble in water, and has  $[\alpha]_D = + 65^\circ$ . It contains 2·07 per cent. N.

40.  $\zeta$ -Invertan results from the splitting up of  $\epsilon$ -invertan in the same way that the latter is formed from  $\delta$ -invertan. Its optical activity is  $[\alpha]_D = + 75^\circ$ , and it yields 1·61 per cent. N.

41.  $\eta$ -Invertan is formed by the action of boiling sulphuric acid on  $\zeta$ -invertan. It contains less nitrogen than the latter substance, but the substance has not yet been sufficiently investigated to give reliable figures.

42. The further products of the action of sulphuric acid on  $\zeta$ -invertan are two soluble substances, one containing a considerable amount of nitrogen, and the other with little or no nitrogen, a high cupric reducing power and a low (dextrorotatory) optical activity.

43. The properties of all the members of the series, except  $\alpha$ -invertan, are very similar. They are all soluble in water, forming bright solutions, which do not cloud on boiling. They are all readily thrown out of solution by alcohol, provided a little acid is present; the precipitates so formed are transparent colourless syrups, miscible with water in all proportions. The solutions are all dextrorotatory.

44. All the members of the invertan series, except  $\eta$ -invertan, yield a pink colouration on boiling with Millon's reagent.

45. All the members of the invertan series, except  $\alpha$ -invertan, when submitted to the action of an alkaline copper solution, readily yield a very characteristic copper compound, from which the invertan (except  $\beta$ -invertan)

may be separated unaltered. Invertan can probably form several such copper compounds, all having a similar appearance, but affording different percentages of copper oxide.

46. In the presence of a very large excess of alkali, a copper compound is also formed from  $\alpha$ -invertan, but on examination it is found that the  $\alpha$ -invertan has been split up into an albuminoid and  $\zeta$ -invertan, the copper compound being that of  $\zeta$ -invertan.

47. It is believed that the members of the invertan series are combinations of yeast albuminoid with  $\eta$ -invertan, and that yeast albuminoid itself is probably a combination of yeast albuminoid with a carbohydrate.

48. According to this theory the composition of the carbohydrate present in the invertan series, calculated from the average of all the analyses, would be C = 43·22 per cent. and H = 6·28 per cent. These numbers agree very closely with those required by a hypothetical carbohydrate coming midway between the *in* and the *on* groups.

49. It is thought that  $\eta$ -invertan contains 18 parts by weight of this carbohydrate to 1 of albuminoid, and that  $\alpha$ -invertan contains 3 parts of the carbohydrate to 4 of albuminoid.

50. The other members of the series are formed by the union of these two substances according to the general formula  $\eta + \alpha_n$ , where  $\eta$  represents  $\eta$ -invertan and  $\alpha$  represents  $\alpha$ -invertan. In this way we look upon invertase ( $\beta$ -invertan) as  $\eta\alpha_3$ . This splits up into  $\alpha$ - and  $\gamma$ -invertan according to the formula  $\eta\alpha_3 = \eta\alpha_1 + \alpha$ .  $\eta\alpha_1$  represents  $\gamma$ -invertan, and this may be further transformed by elimination of  $\alpha$  into  $\eta\alpha_2$ , or  $\delta$ -invertan.

60. The numbers calculated for the constitution of the above theoretical homologous series agree with considerable closeness with those obtained from the analysis of members of the invertan series.

61. The number obtained from a single determination by Raoult's freezing process for the molecular weight of  $\zeta$ -invertan is considerably less than the possible molecular weight of  $\zeta$ -invertan, according to the authors' theory of its constitution.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

### (A.)—CHEMISTRY OF FOOD.

#### PATENTS.

*Improvements in the Method of and Apparatus for Preparing Milk so as to Enable the same to be Preserved Indefinitely.* J. F. H. Gronwald and E. H. C. Oehlmann, Berlin, Germany. Eng. Pat. 6280, April 12, 1889. 11d.

THE milk if acid is neutralised with potassium bicarbonate. It is then placed in a pan with a closely fitting lid and steam jacket. It is then heated to  $100^\circ\text{C}$ . by admitting steam into the jacket and into the space above the milk. The vessels (usually bottles) into which the sterilised milk is to be transferred are first sterilised by means of steam in a chamber specially constructed for the purpose; the milk is then forced over from the pan into a vessel which is situated in the chamber above mentioned, and from this vessel it is run into the bottles. By means of an ingenious arrangement the bottles are closed hermetically with stoppers whilst still in the chamber. Glazed slots in the sides of the chamber enable one to observe what is going on inside. For filling larger vessels, such as casks, a modified chamber is employed but the principle is the same. 100 litres of milk can thus be worked up at a time.

—F. W. T. K.

*Improvements in the Preparation and Combination of Animal Substances with Vegetable Substances for Use in Food.* J. L. Johnston, London. Eng. Pat. 8945, May 29, 1889. 4d.

The animal ingredients, such as powdered meat, albumen, meat peptone, and gelatin or other suitable thickening ingredient are thoroughly mixed with chocolate, cocoa, or coffee extract, and heat is applied so as to reduce the whole to a solid consistency. By means of suitable compressing apparatus lozenges or tablets are prepared. The cocoa and chocolate are preferably previously deprived of their vegetable fat, but flake cocoa or an infusion at once from the nibs may be used. The infusion of coffee is filtered from the residual grounds before being incorporated with the meat preparation above mentioned.

*Soluble Saccharin* is employed to sweeten the preparations if this is necessary. For use the preparation is infused with hot water so as to make a broth.—F. W. T. K.

*Improvements in Food Preparations.* G. A. Brinck and A. W. Rehnström, Stockholm, Sweden. Eng. Pat. 10,352, June 25, 1889. 6d.

This food, which is intended for human beings, horses, dogs, and other animals, is prepared in the form of cakes, bread, biscuits, puddings, and sausages. The ingredients are varied both in quality and quantity according to special requirements. The principal ingredient which is used throughout is dried and crushed milk curds (casein). Other ingredients are, flour or any suitable form of meal, butter, lard, fat, or other animal or vegetable ingredients, and mineral matters (usually in the proportion of 1 to 3 per cent.), bone flour being especially desirable.

—F. W. T. K.

*Improvements relating to the Manufacture of Butter and to Apparatus therefor.* H. H. Lake, London. From F. R. Nörlöw, Copenhagen, Denmark. Eng. Pat. 12,360, August 3, 1889. 8d.

The object of this invention is to produce butter which shall be free from the milk-sugar and albuminous substances contained in the milk. The cream or the fresh milk is centrifugally forced through a perforated or porous material such as wire gauze, woven fabric, clay.—F. G. C.

## (B.)—SANITARY CHEMISTRY.

### PATENTS.

*Improvements in the Clarification or Purification of Sewage and other Foul Waters of Analogous Nature.* C. H. Harvey, London. Eng. Pat. 6994, April 26, 1889. (Second Edition.) 6d.

This invention consists in the use of "acid ferrie salts prepared from waste sulphide of iron, in conjunction with an alkaline earth."—F. G. C.

*An Improved Process and Means to be Employed for Partially Destroying and Mixing Night-Soil and other Refuse, and for Converting the same into Manure suitable for Grass Land and Arable Purposes.* J. W. Lodge, Sowerby Bridge. Eng. Pat. 9087, June 1, 1889. 6d.

By means of a series of reciprocating and revolving riddles and rollers, combustible and metallic portions of the town refuse are separated; the former are burnt, the latter are destroyed in a cupola, the saleable portions, however, being recovered. The residual portion is crushed and ground and finally mixed off with excreta and urine, the mixture being deodorised with sulphuric acid and dried by the addition of

gypsum. Mixed excreta and ashes and other refuse found in old ash-places and privies are subjected to a preliminary treatment of blending and mixing, being at the same time rendered friable, before they are passed through the above apparatus and finally made into manure.

The machinery may also be used for grinding and preparing basic or other slag, cinders, and cement, in fact, anything which needs to be pulverised and separated. This improved machinery may also be used for mixing materials for the manufacture of briquettes made from coal dust in combination with tar and other ingredients.—F. W. T. K.

*Improvements connected with the Filtration of Water and in Cleansing the Filters.* G. W. Hawksley, Sheffield. Eng. Pat. 9512, June 8, 1889. 8d.

INSTEAD of purifying the water by mixing precipitants with it and running the mixture into settling tanks, the precipitants are admitted into the water as it passes through the suction pipe of a pump or pumps which are employed to force the mixture through a series of filters. One advantage claimed for this method is economy of space. For cleansing the filters the inventor does not proceed in the usual way, *i.e.*, by reversing the flow of unfiltered water, but forces the water, filtered by one or two of the filters, through the remaining ones in the reverse direction. Or instead of using water for the purpose he blows steam through the filters in the reverse way or charges them with steam and then suddenly blows it off. This breaks the deposit and causes it to crumble, and it is then carried off through the sludge pipe in which test taps or gauge glasses are fixed for the purpose of watching the cleansing process. An intermediate high pressure tank for the purpose of more thoroughly mixing the ingredients and retaining the grosser deposit and floating material may be inserted between the pump and the filters.

Charcoal, asbestos cloth, wire gauze or other materials supported in one or more layers by perforated filter plates fixed inside the filters are used as filtering media.

—F. W. T. K.

*Improvements in Apparatus for Purifying Water.* W. Anderson, Westminster. Eng. Pat. 10,706, July 2, 1889. 8d.

This is an improvement on Eng. Pats. 5496 of 1883 and 12,256 of 1884 (see this Journal, 1884, 529, and 1885, 133, 363, 546). The water to be purified is admitted into one end of a revolving cylinder on the inside of which are fixed curved radial shelves instead of flat radial shelves, as heretofore used. These shelves are made up of short lengths, about 3 ft., and serve to hold up the iron which is the purifying agent, and by placing them in echelon instead of in lines parallel to the axis throughout, a more uniform stress is brought to bear on the driving machinery, and the iron is more thoroughly brought into contact with the water. The curved plates hold more iron than the flat ones. The water before and after passage through the cylinder is aerated by means of jets of air passed in through perforated pipes. A perforated pipe also passes along the axis of the cylinder, and the air forced through this aerates the water during its passage through the same. This aeration promotes the chemical action which takes place. The excess of air is allowed to escape by means of an automatic valve in the cylinder case. The entrance to the outlet pipe is covered with a hood, to prevent iron being carried away. It is sometimes necessary to keep the iron in more compact masses. Instead of using longitudinal shelves, the cylinder is then divided into transverse cells with perforated sides. These are filled with iron, and the water is made to flow in a sinuous manner between these cells, so as to have as long a contact as possible. The cells are filled through apertures in the cylinder sides, which are closed by means of doors.

—F. W. T. K.

*A System of Purification and Filtration of Water for City and Town Supplies.* J. A. Crocker, Brooklyn, U.S.A. Eng. Pat. 5445, April 10, 1890. 8d.

IN combination with a water supply, this inventor uses a battery of filters, one or more interposed precipitating basins, a precipitating solution tank situated nearest the inlet of the basin supply, and one or more pumping, lifting, and reservoir-distributing stations.—E. G. C.

### (C)—DISINFECTANTS.

#### PATENT.

*A Composition for Arresting or Preventing Decay in Wood.* J. T. McMahon, London. Eng. Pat. 13,203, August 21, 1889. 4d.

THE components of this preparation are as follows: Mercuric chloride,  $1\frac{3}{4}$  oz.; ammonium chloride, 3 oz.; soft soap, 5 lb.; methylated spirit, 2 galls.; distilled water, 1 gall.; Venice turpentine, 10 oz.—E. G. C.

## XIX.—PAPER, PASTEBOARD, Etc.

#### PATENTS.

*Improvements in the Manufacture of Paper.* J. Craig, Cheadle. Eng. Pat. 9145, June 3, 1889. 8d.

THIS invention relates to the production of duplex or triplex paper having suitable designs impressed upon it. For this purpose a web of paper is passed between a pair of metal rollers furnished with punches, whereby the design is punched out. This paper is then united with a web of paper in process of manufacture, as in the ordinary method of making duplex paper. Three sheets can also be so united to form a triplex paper.—E. J. B.

*Improvements in Machinery or Apparatus used in the Manufacture of Paper and Cardboard.* A. Durand, Paris, France. Eng. Pat. 11,779, July 24, 1889. 11d.

THIS invention relates to improvements in the driving of paper and cardboard machines, whereby greater uniformity and increased speed are obtained. For this purpose the power is transmitted by a system of cones instead of spur gearing. The inventor also claims the utilisation of exhaust steam for heating the drying cylinders by means of a novel apparatus. Complete drawings accompany the specification.—E. J. B.

*Improvements in Apparatus for Cutting up Wood into Discs for use in making Wood Pulp.* H. Wigger, Unna, Germany. Eng. Pat. 14,563, September 16, 1889. 6d.

INSTEAD of cutting up the wood into discs with saws, as at present practised in the Mitscherlich process of manufacturing wood pulp, the inventor causes the logs of wood, previously barked, to be acted upon by a revolving knife. The wood is presented to the knife obliquely, both as regards the vertical and horizontal planes. Complete drawings accompany the specification.—E. J. B.

*Improvements in the Process of and Means for Purifying Paper Pulp.* C. Kellner, Vienna, Austria. Eng. Pat. 4960, March 29, 1890. 8d.

ACCORDING to this invention paper pulp largely diluted with water (1–15 oz. per gall.) is caused to flow into a rapidly revolving cylinder placed inside a fixed cylinder. As the inner cylinder revolves the heavy impurities are thrown towards the sides, while the purified pulp flows away in a continuous stream from the centre. As the

impure pulp enters at the bottom of the cylinder in a continuous stream, the impurities gradually rise along the sides and overflow into the outer cylinder, from which they can be from time to time drawn off.—E. J. B.

*An Improved Process of Softening Brittle Paper Pulp.* C. Kellner, Vienna, Austria. Eng. Pat. 5053, April 1, 1890. 8d.

THE inventor causes the pulp to pass into the space between two cones, one of which is rapidly revolving. The cones are covered with helical flutings. Pulp-treating in such an apparatus is more uniform than that produced by the ordinary beating engines. In another form of apparatus the pulp is caused to flow between two horizontal millstones.—E. J. B.

*Improvements in Apparatus for Use in the Manufacture of Wood-Wool.* Ole Evenstad and Olaus Senstad, Rasten Storelvedalen, Norway. Eng. Pat. 8422, May 30, 1890. 6d.

AN apparatus is described for cutting wood shavings into longitudinal strips. It is specially designed for use in combination with the machine patented by the same inventors (Eng. Pat. 4296 of 1888).—E. J. B.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*The Oxidation of Turpentine in Sunlight.* H. E. Armstrong. Proc. Chem. Soc. 1890 (85), 99–101.

It was pointed out by Sobrero in 1851 (Compt. Rend. **33**, 66) that when turpentine is exposed to light in presence of moisture and oxygen a crystalline substance is formed which has the composition represented by the formula  $C_{10}H_{16}O_2$ ; and that this substance is decomposed when boiled with dilute sulphuric acid, an oil being formed which has a powerful odour recalling both that of camphor and that of turpentine. The author's attention became directed to this substance about 12 years ago in the course of his studies of the terpenes and camphor, and in most years since, during the summer, he has carried on experiments on the oxidation of  $C_{10}H_{16}$  hydrocarbons in sunlight, and has been able to confirm Sobrero's statements in every particular. As the crystalline product in question has not yet been named, it is proposed to term it—at all events, provisionally and until its constitution is determined—sobrerol.

Sobrerol is readily soluble in alcohol, and crystallises from this solvent usually in large, flexible, monosymmetric prisms having a peculiar hour-glass structure inside and showing hemihedrism. It is slightly soluble in water, benzene, chloroform and petroleum spirit; the aqueous solution has a bitter taste. It melts at about  $150^\circ$ . The formula is  $C_{10}H_{16}O_2 = C_{10}H_{16} + H_2O_2$ , and there can be very little doubt that it is a glycol. Sobrerol is optically active in a high degree, the apparent specific rotatory power of the products from French turpentine in a 5 per cent. solution in alcohol (b.p.) being slightly above  $150^\circ$ . Sobrerol from American turpentine (from Savannah) was found to have about the same rotatory power, but in the opposite direction. The optical similarity of the two products is noteworthy, inasmuch as the American has less than half the rotatory power of French turpentine. It would seem that only the terpenes proper, and not the citrenes, &c. (Chem. Soc. Trans. 1879, 734; this Journal, 1882, 478) form sobrerol.

When boiled with dilute sulphuric acid, sobrerol is readily converted into the oil referred to by Sobrero; the product is undoubtedly identical with the isomeride of camphor which Wallach and Otto have obtained by treating turpentine

with nitrous acid (Annalen, 253, 249), and which they have provisionally named *pinol*: as the compound is not an oil, i.e., an alcohol, it may be suggested that it might appropriately be termed *sobrerone*. The product from sobrerol begins to boil at  $150^{\circ}$ – $160^{\circ}$ , but passes over almost entirely at about  $183^{\circ}$ , leaving a small amount of a viscid oil; it readily combines with bromine, forming a dibromide (bromine found 50.78 per cent.) which crystallises very beautifully in forms of the rhombic system. The dibromide was found to melt at  $93.5^{\circ}$ .

Sobrerol is probably always the initial product of oxidation of turpentine. It may be expected that soberone will be found among the oxygenated constituents of some essential oils, and it is proposed to search for it.

*A New Lutidine.* E. Dürkopf and H. Göttisch. Ber. 23, 1113–1114.

This base was obtained from dimethylpyridine carboxylic acid, itself obtained by the oxidation of the parvoline, boiling at  $216^{\circ}$ – $217^{\circ}$ , and proved by the authors to have the constitution represented by the formula—

(Ber. 23, 1110–1112). It was formed by eliminating carbonic anhydride, boils at  $169$ – $170^{\circ}$ , and has the composition  $C_7H_9N$ , agreeing with that of lutidine. It is a colourless highly refractive liquid, having a feeble and not unpleasant odour. It dissolves sparingly in cold, more readily in hot water. It has a specific gravity of 0.9614 at  $0^{\circ}$  (water at  $4^{\circ}$ =1). The *mercuriochloride* crystallises in fine long sparingly soluble needles, melting at  $170^{\circ}$ . The same base is formed in small quantities by the action of propaldehyde-ammonia on propaldehyde, it being found possible to isolate from the fraction boiling at  $170^{\circ}$ – $180^{\circ}$  a base agreeing in all its properties with the above lutidine. In order to determine the constitution of the latter, the base was subjected to oxidation, a product being obtained the analysis of which showed it to be a pyridinedicarboxylic acid. It melts at  $314^{\circ}$ – $315^{\circ}$ . From its high melting point and external character the authors infer that the acid is dimaleic acid, so that by regarding the above lutidine as a  $\beta\beta$ -dimethylpyridine its constitution is represented by the formula—

—D. B.

*On the Composition of Digitonin.* H. Kiliani. Ber. 23, 1555–1560.

DIGITALIN of commerce contains besides digitoxin (used in pharmacy and not yielding any sugar by heating with acids) at least three glucosides: digitonin, digitalin, and digitalein, of which the first is present in greatest quantity and appears to be identical with saponin. It has been observed by various observers that digitalin when heated with acids yields bodies capable of reducing cupric oxide, and Schmiedeberg has observed that there is also formed a crystalline body insoluble in water which he named *digitogenin*. He described some of the properties of this body, but did not determine the nature of the sugars formed. The author has made further experiments to determine the nature of these bodies.

Some commercial digitalin (pur. pulv.) was obtained; it was almost completely soluble in water. Emulsion was without action on it. It was treated with its own weight of hydrochloric acid (1.19) diluted with 10 times its weight of

water, at the boiling point for six hours. As the reaction progressed an insoluble substance separated out, which at the conclusion was filtered and washed with water.

The filtrate was treated with silver oxide to remove hydrochloric acid and evaporated to a syrup; on exposure over sulphuric acid in a desiccator, it solidified to a crystalline mass. This was treated with boiling methyl alcohol, and a sugar was left, which was found to be galactose, the methyl alcohol solution was found to contain dextrose and a little more galactose. About 16 per cent. of each sugar was obtained. The insoluble body was about 50 per cent. of the digitalin taken. It was purified by dissolving in chloroform, distilling this off and treating the residue with a little boiling alcohol, which dissolved out most of the dirt and recrystallising the residue from 30–40 times its weight of boiling alcohol. To determine if this was a pure body, it was fractionated into four portions, and these were found to be identical. A determination of the carbon and hydrogen pointed to the formula  $(C_{15}H_{21}O_3)_x$ ; the composition of crystallised derivatives of digitogenin to the formula,  $C_{15}H_{21}O_3$ .

Digitogenin is soluble in 35 parts of boiling and in more than 100 parts of cold 93 per cent. alcohol; in 20 parts of boiling and 30 parts of cold chloroform; in 30 parts of cold glacial acetic acid, and in rather less of hot, and it is insoluble in water and aqueous potash. With alcoholic potash it forms a crystalline potash compound. Phenylhydrazine does not act on it, nor does a hot concentrated solution of baryta form any well marked compound, whilst mineral acids and oxidising agents act energetically.

The reaction is expressed by the following equation—

*Manufacture of Tannins free from Colouring Matter.* A. Villon. Bull. Soc. Chim. 1890, 784–786.

To prepare tannin free from colouring matters from chestnut wood, quebracho, divi-divi, sumac, and other astringents, an extract is first obtained in the usual way, using six vats and a current of carbonic acid, at a temperature of  $80^{\circ}$ – $90^{\circ}$ , this is cooled in ordinary settling vats, the liquor drawn off, 0.5 per cent. of zinc sulphate added, the temperature is then maintained for half an hour at  $+2^{\circ}$  by means of a refrigerating vat similar to those used in breweries; the precipitated impurities are separated in a filter-press. The filtrate is transferred to a closed vat, provided with a mechanical agitator, a solution of zinc sulphate is then added in the proportion of 2.5 kilos. of the salt per kilo. of tannin present; and a current of ammonia gas (obtained by decomposing 2.5 kilos. of ammonium sulphate per kilo. of tannin) is passed in and the whole heated to boiling; the excess of gas is collected in another vat. Tannate of zinc is thus precipitated, and ammonium sulphate left in solution; the former is separated in a filter-press, washed successively with warm and cold ammoniacal water and with cold water, suspended in five times its volume of water, and decomposed with dilute sulphuric acid; a solution of barium sulphide is then added till no further precipitate is formed. The precipitate, which consists of zinc sulphide and barium sulphate, is removed by filtration, an almost colourless liquid is thus obtained, containing 20–30 per cent. of tannin ( $10^{\circ}$ – $15^{\circ}$  B.) and quite free from extractive matters. The ammonia is recovered from the filtrate from the zinc tannate; the mixed precipitate of zinc sulphide and barium sulphate is treated with dilute sulphuric acid, zinc sulphate passing into solution, the barium sulphate is then reconverted into the sulphide by calcination with coal.

The above process is quite as economical as the ordinary methods of manufacturing extracts.—S. B. A. A.

## PATENTS.

*Improvements in the Separation of the Isomeric Substances produced in the Manufacture of Dithiosalicilic Acid.*  
A. M. Clark, London. From Dr. F. von Heyden's Nachf., Radebeul, Germany. Eng. Pat. 13,027, August 17, 1889. 4d.

The dithiosalicilic acid produced according to Eng. Pat. 14,443 of 1888 (this Journal, 1890, 213), is a mixture of two isomerides which can be easily separated in the form of their salts. The less soluble dithiosalicylate No. 1. may be precipitated with common salt from the aqueous solution of an alkali salt of the crude acid. Another way is to treat the dry sodium salt of the crude acid with boiling alcohol, which dissolves only the sodium dithiosalicylate, No. II.

—E. G. C.

*Improvements in the Production of Quinazoline Derivatives.*

H. H. Lake, London. From Kalle and Co., Biebrich-on-the-Rhine, Germany. Eng. Pat. 13,343, August 23, 1889. 6d.

A PROCESS for the preparation of new pharmaceutical products belonging to the dihydroquinazolines and having the general formula,—

The two methods given for the preparation of these bodies are: (1.) Reducing formyl-*o*-nitro-benzylaniline, formyl-*o*-nitrobenzyl-*p*-toluidine, formyl-*o*-nitrobenzylanisidine, formyl-*o*-nitrobenzyl-*p*-phenetidine and similar products. (2.) Treating *o*-amidobenzylaniline, *o*-amidobenzyl-*p*-toluidine, *o*-amidobenzyl-*p*-anisidine, *o*-amidobenzyl-*p*-phenetidine and similar products with formic acid. The reactions which take place are expressed by the following equations—

I.

II.

In working according to the first method 10 kilos. of *o*-nitrobenzylformanilide, melting point 77° (by heating 10 parts of *o*-nitrobenzylchloride with 8 parts of sodium formanilide in benzene) (see also Lellman and Stichel, Ber. 19, 1604) are reduced in 30 kilos. of alcohol with 14 kilos. of tin and 28 kilos. of hydrochloric acid. A salt having the formula,  $\text{C}_{14}\text{H}_{12}\text{N}_2\text{HClSnCl}_2$ , melting point 130°–134°, crystallises out, and when freed from tin yields the hydrochloride of phenylhydroquinazoline. This latter compound is also obtained by reducing *o*-nitrobenzylaniline with ammonium sulphide and boiling the *o*-amidobenzylaniline thus obtained with an excess of formic acid. The solution is then diluted with water, filtered, precipitated with soda, and the base obtained dissolved in dilute hydrochloric acid. On evaporation crystals of phenylhydroquinazoline hydrochloride separate out. It has the formula  $\text{C}_{11}\text{H}_{12}\text{N}_2\text{HCl} \cdot 2 \text{H}_2\text{O}$  and melts at 80°. When anhydrous it melts at 220°. The salt is easily soluble in water and alcohol, but can be precipitated from its aqueous solution by means of salt. The base melts at 95° and is almost insoluble in water, but very easily soluble in alcohol and ether. The properties of the following substances are also given:—

*p*-Tolyldihydroquinazoline—

Its hydrochloride crystallises with two molecules of water and melts at 85°. The anhydrous salt melts at 221°. The base crystallises in leaflets melting at 120°.

*p*-Anisylidihydroquinazoline—

white needles, melting point 85°.

*p*-Phenetyldihydroquinazoline—

white leaflets, melting point 109°.

The phenylhydroquinazoline is known as orexine (see this Journal, 1890, 321).—T. A. L.

*A Process for the Production of Thio-oxydiphenylamine.*

M. Lange, Amersfoort, Holland. Eng. Pat. 15,706, October 7, 1889. 4d.

A SALT of *m*-oxydiphenylamine is heated in an aqueous solution with or without the addition of an alkali or alkaline carbonate and in an open vessel or in a digester. 250 kilos. of caustic soda are dissolved in water and 185 kilos. of "*m*-oxydiphenylamine salt" are added. The solution is heated and 200 kilos. of sulphur are gradually introduced and the mixture boiled until all the sulphur is dissolved. On adding sodium bicarbonate to the hot liquor the thio-product is precipitated as a light yellow powder. It is easily soluble in alkalis, less so in alkaline carbonates, and is precipitated from its solutions by acids and acid salts as a light yellow tasteless powder. It is also soluble in alcohol and acetic acid, but insoluble in water and benzene. The melting point is about 155°. The product is to be used as a substitute for iodoform as a dressing for wounds. It has no smell and is innocuous.—T. A. L.

## XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

## PATENTS.

*Improvements in Indelible and Waterproof Prints, Pictures, Designs, and similar Objects, and in the Method of Producing the same.* J. R. France, New York, U.S.A. Eng. Pat. 20,964, December 31, 1889. 6d.

THE inventor places a print, photograph, or design on paper, linen, or other suitable material between thin transparent sheets of celluloid, uniting them by means of any suitable solvent for celluloid, or by a transparent size or gum.—E. J. B.

*Improvements in the Manufacture of Nitro-cellulose and Apparatus for that Purpose.* J. R. France, Plainfield, New Jersey, U.S.A. Eng. Pat. 5364, April 8, 1890. 6d.

CELLULOSE intended for conversion into nitro-cellulose is first reduced to a fine state of division by suitable machinery, which is fully described in the specification.—E. J. B.

## XXII.—EXPLOSIVES, MATCHES, Etc.

## PATENTS.

*Improvements in Fuses and Detonators.* P. Ward and E. M. Gregory, London. Eng. Pat. 11,500, July 18, 1889. 8d.

This invention is an improvement on Eng. Pat. 3981 of 1884, whereby the electric fuses and detonators are rendered absolutely impervious to the action of moisture, air, &c.

The detonating composition is introduced into a glass tube, in the closed end of which two wires have been previously sealed. A small plug of any suitable non-inflammable substance, such as asbestos, slag-wool, &c., is inserted on top of the explosive composition and the open end of the glass tube is fused together in the blow-pipe, or closed by a sufficient quantity of Chatterton's composition, sealing wax, or other suitable substance. Detailed descriptions and drawings are given of the methods and tools employed for preparing the glass tubes so that an absolutely uniform arrangement of the wires is ensured, both as to the surface exposed and their separation from each other.

—W. M.

*Improvements in the Preparation and Application of Explosive Compounds.* A. V. Newton, London. From A. Nobel, Paris, France. Eng. Pat. 12,307, August 2, 1889. 6d.

This specification describes a manner of forming propelling charges for firearms out of smokeless explosives of the celluloidal kind, the charges "consisting of rolled up sheets, or plates, or tubes, or hollow caps, corrugated or pierced with holes, for the purpose of increasing their surface of explosive combustion."—W. M.

*Improvements in the Manufacture of Lucifer Matches.* J. Lutz and L. Oltozy, Vienna, Austria. Eng. Pat. 12,763, August 13, 1889. 4d.

In this invention the matches are made by dipping the ends of the splints in bundles into a solution composed of 30 parts by weight of water, 20 parts of sodium chlorate, 4 parts of ammonium sulphate, and 2 parts of gum arabic, sugar, or other carbohydrate, and afterwards allowing them to dry. The matches thus made differ from those in ordinary use in having no enlarged heads. They ignite when rubbed on a surface covered with amorphous phosphorus and antimony trisulphide.—W. M.

*Improvements in Damp-Proof Cartridge Cases.* J. C. Butterfield and T. C. Batchelor, London. Eng. Pat. 14,025, September 5, 1889. 8d.

"This invention relates to the manufacture of cartridge cases, preferably of metal (this Journal, 1890, 765), which shall be impervious to damp or water, and consists in the employment of an inner pocket in which the fuse is placed when the cartridge is to be exploded."

In one form the pocket is cylindrical and concentric with the axis of the cartridge. In another it is simply a longitudinal groove in the outside of the cartridge case, the detonator being placed either inside the pocket or in the groove, and held in position by binding. In either case the detonator when exploded destroys the wall of the pocket or groove and explodes the cartridge. In this way a cartridge case is provided which does not require to be cut or opened in any way previous to firing.—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

*Determination of the Specific Gravity of Salts Soluble in Water.* J. W. Retgers. Zeit. f. Phys. Chem. 3, 289.

The published determination of the specific gravity of salts varies very much. The discrepancies are chiefly due to the difficulty of obtaining crystals free from cavities, these imperfect crystals being always lighter than the homogeneous ones. The author recommends that a liquid be prepared of such a density that only the heaviest, and consequently the homogeneous crystals float in it, whilst the lighter ones, that is those containing cavities, float on the surface. A mixture of methylene iodide and benzene is a convenient liquid. A few determinations made by this method are given.—A. L. S.

*A New Reaction of Hydrogen Peroxide.* G. Denigès. Bull. Soc. Chim. 1890, 797.

ONE or two cc. of a 10 per cent. aqueous solution of ammonium or sodium molybdate, containing an equal volume of concentrated sulphuric acid acquires on addition of a few drops of hydrogen peroxide a yellow colouration approaching in intensity that of solutions of the alkaline chromates and bichromates. The intensity of the colour is rapidly diminished on addition of water, and more gradually on diluting with sulphuric acid; it is slowly destroyed by nitric acid in the cold and speedily on warming. The reaction is not affected by boiling, and is probably due to the formation of a permolybdic acid; it is sufficiently sensitive to detect 0.1 mgrm. of hydrogen peroxide, whereas the chromic reaction does not indicate less than 0.5 mgrm.—S. B. A. A.

*Easy Method of Determining Nitrogen in Sodium Nitrate.* O. Foerster. Chem. Zeit. 14, 509—510.

Two to 3 grms. of the sample to be tested are weighed into a fair-sized porcelain crucible of known weight and dried at 150° or at such a temperature that the salt just commences to fuse. After cooling and weighing, the mass is dissolved in 25 cc. of hydrochloric acid of 19 per cent. strength and dried on the water-bath, the addition of acid and subsequent drying being thrice repeated to ensure the conversion of all nitrate into chloride. The crucible is next heated for a little time to 150°, then to a dull-red heat over the bare flame, and afterwards cooled and weighed, the result being calculated on the basis of 61.89 parts of NO<sub>3</sub> being replaced by 35.37 parts of Cl.

Satisfactory results are obtained with this method in the testing of Chili saltpetre, except when this substance has been sophisticated with magnesium chloride, in which case the method is unavailable.—E. B.

*The Separation of Copper from Arsenic by Electrolysis.* L. W. McCay. Chem. Zeit. 14, 509.

If the current from 4—6 Meidinger's cells be passed through a solution of an alkaline arsenate rendered alkaline with ammonia, no separation of arsenic or reduction of the arsenic acid takes place. If, however, such a current be passed through an ammoniacal solution of a copper salt, complete separation of the copper in time takes place. The experiment was tried with a mixture of known quantities of copper salt and potassium arsenate, to which ammonia in slight excess had been added, and it was found that 6 hours' passage of the current sufficed to remove the blue colour of the solution. The current, however, was continued for 18 hours longer, to ensure the complete reduction of the copper. The copper was then weighed and found to be quantitatively separated, the original amount also of arsenic acid being found in solution.

—E. B.

*The Analysis of Sodium Aluminate.* K. J. Bayer. Chem. Zeit. **14**, 736--737.

LUNGE has recently published (Zeits. f. angew. Chem. 1890, 227; this Journal, 1890, 766 and 767) a method of analysis of sodium aluminate similar in detail to the method previously described by the author (Zeits. Anal. Chem. **24**, 542; 1886, **25**, 180; this Journal, 1886, 41 and 550). Lunge, however, takes into consideration the silicic acid which may happen to be present, making, when this is the case, a deduction from the volume of standard acid required to change the tint of the methyl-orange indicator, *i.e.*, corresponding to the alumina present. This, the author states, is incorrect, since silicic acid has for acids no neutralising power whatever. For, if a solution of sodium silicate be titrated with standard acid, and either methyl orange or phenolphthalein, practically the same result is obtained; thus, in an actual experiment, 11.60 cc. of acid were required with methyl-orange as indicator against 11.45 cc. with phenolphthalein, the slight difference being due to the presence of alumina in the sample.

Lunge further states that the volumetric method in question is inapplicable to the determination of alumina in solutions containing much silica. To this objection the author rejoins that the method is intended for the analysis of sodium aluminate, and that sodium aluminate is no more likely to contain more than traces of silica than sodium silicate is of alumina. As a matter of fact, when solutions of sodium aluminate and silicate are mixed together, a voluminous precipitate is obtained, forming slowly in dilute solutions, but, in stronger ones, usually causing the whole mass to set to a jelly. When washed and air-dried this precipitate has the constant composition—

It forms an exceedingly fine, loose, probably crystalline powder, easily soluble in acids and sufficiently so in water to communicate an alkaline reaction thereto. Dissolved in a known amount of normal acid and titrated back with standard soda and methyl-orange, the volume of acid found to be neutralised corresponds to the alumina and soda contained in the compound. When, however, phenolphthalein is used as indicator a lower figure is obtained than would correspond to the soda alone which is present, the original compound, or a similar one, thus appearing to be partially regenerated. It was found, for example, that 0.2140 grm. of the crystalline compound neutralised 3.45 cc. of normal acid (1,000 cc. = 29.68 grms. of  $\text{Na}_2\text{O}$  or 16.37 grms. of  $\text{Al}_2\text{O}_3$ ) with methyl-orange as indicator, and with phenolphthalein 0.4458 grm. of substance neutralised 1.02 cc. of acid instead of 1.58 cc. actually corresponding to the soda in the compound. Now the amount of silica present in the solution of sodium aluminate tested by Lunge appears to be as high as can possibly be contained in the same, and yet from the above considerations it only causes in the determination an error of 0.014 cc. of standard acid, and may therefore be neglected. It is, moreover, worthy of note that the very slight error in the method, when silica is present in the solution to be tested, extends to the soda as well as the alumina, the percentage of the former being lowered in proportion as that of the latter is raised.

The only defect in the method, in the author's opinion, is the difficulty of obtaining a sharply-defined end-reaction, but this, after practice, can be obtained to within a couple of drops of acid. Of more practical consequence is the fact that each part of silica which remains behind, as almost all of it does, in the form of—

on lixiviating the roasted raw material, represents a loss of 0.37 part of  $\text{Al}_2\text{O}_3$  and 0.34 of  $\text{Na}_2\text{O}$ .—E. B.

*On the Estimation and Separation of Zinc in the Presence of Iron and Manganese.* J. Ribau. Compt. Rend. **110**, 1196--1199.

THE author bases his method on the following facts, which he has previously proved (Compt. Rend. **107**, 341; this Journal, 1889, 771):—(1.) Zinc in the presence of alkaline

thiosulphates or ammonia gives with hydrogen sulphide a dense granular precipitate of sulphide insoluble in cold thiosulphuric acid, which is here liberated. (2.) Iron is not precipitated in such a solution; the zinc precipitate carries down only a trace of iron.

The solution containing zinc, iron, and manganese is diluted until it contains not more than 1 grm. of zinc per litre. Sodium carbonate is added until a precipitate is just formed, and then is dissolved by a drop of dilute hydrochloric acid. Sulphuretted hydrogen is passed into the cold solution until the greater part of the zinc is precipitated together with some sulphur caused by reduction of the ferric chloride, a large excess of sodium thiosulphate is added, and the current of sulphuretted hydrogen continued until all the zinc is precipitated.

When it is desired to precipitate the iron with ammonia, after removing the zinc, it is preferable to substitute ammonium thiosulphate for the sodium salt, as the iron is liable to carry down some alkali with it, and the initial neutralisation should be made with ammonia or its carbonate.

The precipitate of zinc sulphide is allowed to stand five or six hours. It is then filtered off, washed with sulphuretted hydrogen water, dried in a current of hydrogen, and weighed as zinc sulphide. Several analytical numbers are given, showing that the amount of iron or manganese carried down with the zinc is so small as to be negligible.—A. L. S.

*On the Composition of Clays and Kaolins.* G. Vogt. Compt. Rend. **110**, 1199--1202.

THE author has made experiments which show that it is not possible by levigation to separate pure aluminium silicate from finely-divided quartz, felspar, or mica.

If clay, mica, quartz, or felspar be treated separately by sulphuric acid, the two first will be dissolved and the other will not. Thus a clay containing quartz, felspar, and mica may be separated into two parts by sulphuric acid. If either or both of these portions contain alkali, the origin of the alkali is determined.—A. L. S.

*Oxidising and Decolourising Properties of Charcoal.* P. Cazeneuve. Bull. Soc. Chim. 1890, 786--788.

See this Journal, 1890, 657.

*Test for Nitrobenzene.* J. Morpurgo. Pharm. Post, 1890, **23**, 258.

INTO a small porcelain basin are brought two drops of melted phenol, three drops of distilled water, and a small piece of potassium hydrate; the mixture is heated to the boil, and a few drops of a mixture of nitrobenzene and water added, when a crimson ring is produced round the edge of the mixture, the intensity of the colouration produced being proportional to the amount of nitrobenzene added; on the addition of a saturated solution of bleaching powder the colour of the ring changes to emerald green.

Use is made of the above reaction in the detection of nitrobenzene, which is effected by mixing with lime the solution of the substance to be tested, evaporating, if necessary, to dryness before extracting with ether, expelling the ether by heat, mixing the residue with a little distilled water, and then applying the test.—E. B.

*Researches on Diazo-compounds.* L. Gattermann. Ber. **23**, 1218--1228.

COPPER in a finely-divided state acts upon diazo-compounds very energetically even at 0° C., the product being chlorobenzene when diazo-benzene chloride is used, instead of diphenyl as was expected. As a consequence of this observation, it was discovered that the amido-group of aniline and of its homologues can be replaced by bromine and cyanogen, as well as by the nitro- and sulphocyanogen-groups. This reaction, which presents many points of

resemblance to the Sandmeyer's reaction with cuprous salts is in many respects superior to it. For example, it is carried out in the cold, and thus the heating of large volumes of solution is avoided; moreover the yields in consequence of the use of a low temperature are superior.

On acting on diazo-benzene sulphate in presence of alcohol, with copper, diphenyl was obtained on distillation with steam, as principal product. Zinc dust or iron powder yield the same result.

**Preparation of the Copper Powder.**—The copper powder was prepared by gradually dusting zinc powder through a very fine sieve into a solution of copper sulphate, which has to be continually stirred. It is, however, advisable not to continue until the blue solution of copper sulphate is decolourised, but to cease when it yet shows a slight blue tinge. Thus the presence of zinc in the copper is avoided. After decantation and repeated washing, the copper is treated with very dilute hydrochloric acid to remove traces of zinc, and finally washed until the wash-water shows a neutral reaction. It has to be kept moist in tightly closed vessels, being very susceptible to oxidation.

The following transformations were effected, and the percentage yields determined:—Chlorobenzene from Aniline; *o*-Chlorotoluene from *o*-toluidine; *p*-Chlorotoluene from *p*-toluidine;  $\beta$ -Chloronaphthalene from  $\beta$ -naphthylamine; *p*-Chloronitrobenzene from *p*-nitraniline; *m*-Chlorobenzaldehyde from *m*-Nitrobenzaldehyde; Bromobenzene from aniline; Iodobenzene from aniline; *p*-Iodotoluene from *p*-toluidine; Phenyleyanate from aniline; *o*-Tolyleyanate from *o*-toluidine; Diphenyl from aniline.—A. L.

**On the Application of Sandmeyer's Reaction to Diazo-sulphonic Acids, and on the Decomposition of these Compounds in presence of Copper or Copper Oxide.** G. Tobias. Ber. 23, 1628—1634.

THE author has observed that it is not necessary to use as large quantities of copper protochloride as Sandmeyer did for the decomposition of diazo-compounds. He further found that a piece of copper foil covered with a layer of protoxide would act in the same way as copper protochloride, and he also used the agent which has formed the subject of a communication by Gattermann (see preceding abstract), viz., copper powder. Evolution of nitrogen sets in in presence of dilute nitric, sulphuric, acetic, or formic acid and also of methyl and ethyl alcohol. On treating diazonaphthalene sulphonic acid with copper in presence of formic acid, naphthalene disulphonic acid was obtained according to the equation—

Diazonaphthalene sulphonic acid prepared from naphthionic acid was acted upon with copper in presence of alcohol and yielded naphthalene- $\alpha$ -sulphonic acid. Diazonaphthalene disulphonic acid yielded when treated under the same conditions, naphthalene disulphonic acid.—A. L.

**Estimation of Acetone in Methyl Alcohol and in Crude Wood Spirit.** L. Vignon. Bull. Soc. Chim. 1890, 595, —598.

See this Journal, 1890, 659 and 660.

**Estimation of Acetone in Crude Wood Spirit.** Vincent and Delachaux. Bull. Soc. Chim. 1890, 681—82.

THIS is a reply to Messinger's claim for priority for the process described by these authors (this Journal, 1889, 139).—S. B. A. A.

**Estimation of Hydrochloric Acid in Hydroxylamine Hydrochloride.** J. A. Muller. Bull. Soc. Chim. 1890, 605—606.

LÉGER (Jour. de Pharm. [5], 11, 425) found that the acids contained in the salts of most natural alkaloids may be determined volumetrically if phenolphthalein be used as the indicator, since the alkaloids do not redden that substance. The acid in hydroxylamine hydrochloride may likewise be titrated with sodium hydroxide free from carbonate, exactly like an aqueous solution of hydrochloric acid. This determination affords a means of rapidly ascertaining the quantity of soda required in the preparation of aldoximes (by V. Meyer's method) and of acetoximes.

The author finds that pyridine and the picolines and lutidines behave toward phenolphthalein like neutral compounds or sensibly so, and he proposes to utilise Léger's method for the estimation of acids in combination with these substances.—S. B. A. A.

**The Testing of Light Petroleum.** R. Kissling. Chem. Zeit. 14, 508—509.

THE author, having occasion to examine annually a large number of samples of light petroleum, has adopted the method of testing described below. The fractionating flask used is of the form and size recommended by Engler (Chem. Zeit. 10, 1238; this Journal, 1886, 654). 100 cc. of the petroleum sample are measured into the flask, which is connected with a Liebig's condenser 60 cm. long. The flask is supported by a thick piece of wire gauze, such as is used in the filter-presses of sugar refineries. The distillate is received in a cylinder graduated to 0.5 cc. It is advisable, at the commencement of distillation, to make the end of the adapter dip pretty deeply into the cylinder, in order to avoid loss by evaporation of the low-boiling fractions. The rate of distillation is such that 2—2.5 cc. are driven over per minute. When the heat is first applied, the mercury in the thermometer rises rapidly, then more slowly, and next becomes stationary for a while; the last position marks the "lower limit" of the boiling point of the sample. The distillation is now carried on, readings of the volume distilled being taken at intervals of 10°, beginning with the lowest multiple of 10 above the "lower limit." Finally, when the flask has become very nearly empty, the full flame of the Bunsen burner is directed to the bottom of it, and the temperature of the thermometer noted, this temperature being the "higher limit." It is not necessary to drive over the last few drops in the flask, but, should it be desirable to do so, the thermometer should be lowered to the level of the bottom of the neck of the flask. In the following table there are shown some results obtained by this method.

Kind of Petroleum.	Boiling Points Guaranteed by Vendor.	Volume (in cc.) Distilled.												“ Lower Limit.”	“ Higher Limit.”
		30°.	40°.	50°.	60°.	70°.	80°.	90°.	100°.	110°.	120°.	130°.

*Gunning's Modification of Kjeldahl's Method of Estimating Nitrogen.* A. Atterberg. Chem. Zeit. 14, 509.

As certain nitrogenous compounds, such as alkaloids and azo-compounds, are with difficulty completely oxidised by boiling sulphuric acid, the author tried the modified method proposed by Gunning (this Journal, 1889, 823) on two such bodies, namely, quinine and indigo, comparing the results with those obtained by the ordinary Kjeldahl method and the soda-lime method; the results are tabulated below:—

	Nitrogen found in the Sample of	
	Quinine	Indigo.
	Per Cent.	Per Cent.
Original method of Kjeldahl ....	5.80	8.90
	5.99	8.92
Gunning's modified method.....	8.40	9.16
	8.40	9.50
Soda-lime method .....	8.29	9.38
	8.11	9.44

Gunning's method has the advantage of dispensing with the potassium permanganate, mercury, phosphoric acid, and sodium sulphide used in other modifications of Kjeldahl's method, and, besides, has the advantage of being quicker. The author strongly recommends it.—E. B.

*The Estimation of Sugar by a Solution of Copper Carbonate in Potassium Carbonate Solution.* H. Ost. Ber. 23, 1035—1039.

SOLDANI, in 1876, recommended a solution of copper carbonate in potassium carbonate solution in place of Fehling's solution for the estimation of sugar, but the solution did not work well, and does not appear to have had any considerable use. The author has modified the process and states that the solution he recommends gives reliable results with invert sugar, does not reduce cane sugar in the slightest, and possesses the advantage over Fehling's solution, that it is perfectly stable.

The copper solution is prepared by adding a solution of 23.5 grms. of pure crystalline copper sulphate to a solution containing 250 grms. of potassium carbonate and 100 grms. of potassium bicarbonate, and making the solution up to 1 litre.

In a volumetric estimation 50 cc. of the copper solution were decolourised by 25 cc. of a pure 0.4 per cent. solution of invert sugar after 9—10 minutes' boiling. Experiments were made to determine the effect of the presence of various quantities of cane sugar, and it was found that a solution as above, containing 100 parts of cane sugar, (1) to 100 parts or more of invert sugar, required 25 cc. of copper solution; (2) to 20 parts of invert sugar, 24.8 cc.; (3) to 5 parts of invert sugar, 24.5 cc.; (4) to two parts of invert sugar, 24.25 cc.; and (5) to one part of invert sugar, 23.75 cc. of copper solution. In these experiments if Fehling's solution had been used the results would have been much worse.

In a gravimetric determination it was found that when 50 cc. of the copper solution were boiled six minutes with 50 mgrms. invert sugar dissolved in 25 cc. water; 1 mgrm. of invert sugar reduced 3.40 mgrms. of copper, and that if less or more invert sugar were used then each mgrm. of invert sugar reduced less copper, if cane sugar were also present rather more copper was reduced for the same weight of invert sugar. For substances such as raw beet sugar containing a large quantity of cane sugar and only a little invert sugar, a solution containing less copper is used.

Tables are given showing the influence of various amounts of cane sugar in altering the amount of copper reduced by a unit of invert sugar.—A. L. S.

*Rosin Oils: A Method for Distinguishing Oils of the First and Second Distillation; their Alteration by the Action of Air.* A. Cheuvreux. Monit. Scient. 1890, 4, 685—689.

Rosin oils are composed of hydrocarbons belonging to the terpene group and the products of their oxidation, acids, aldehydes, acetones, &c. These last may be considered as impurities, although there are few commercial oils from which they are absent. The author has estimated the quantity of these acids present in different samples by a gravimetric and a volumetric method. By the soap the oil is saponified by caustic soda, the solution of first poured off, the resin liberated from this by hydrochloric acid, dried, and weighed. Its density is 1.02—1.04 and it is a similar body to colophony. By the volumetric method the oil is dissolved in alcohol and titrated with standard soda, using rosolic acid or phthalein as an indicator. Their molecular weight may be taken as 302; on this assumption 85—80 per cent. of resin acids were found in a resin extracted from the oil by the saponification method. The best oils contain the smallest quantity of acid, the rectified oils containing less than 4 per cent. and the commoner varieties from 4 to 10 per cent. of resin acids.

It is well-known that rosin oils thicken considerably on exposure to the air; the author finds that this is unaccompanied by any increase in the amount of resin acids.

—A. L. S.

*The Estimation of Cotton-Seed Oil in Lard.* L. de Koninek. Ned. Tijdschr. v. Pharm. 1890, 22.

A. VAN ASBÖTH found the iodine numbers of oleic acid from lard oil and from cotton-seed oil to be respectively 92 and 134. The author has obtained similar numbers (93 and 135) and proposes to determine the percentage of cotton-seed oil in lard from a consideration of the iodine number of the oleic acid extracted from the mixture. If, for example, this iodine number be 120, the ratio of the amounts of the two acids will be—

$$(134 - 92) : (120 - 92) = 42 : 28,$$

therefore 60 per cent. of the acid is derived from the seed oil. If the total acids form 65 per cent. of the sample, the

acid from the seed oil will form 39 per cent.  $\frac{(65 \times 60)}{100}$

of the sample, this corresponds to 55.5 per cent. of cotton-seed oil, since the latter only contains 70 per cent. of oleic acid. (See this Journal, 1889, 30, 63, 123, 480, 641, 658, and 741.)

The process is conducted as follows: About 3 grms. are saponified with freshly prepared alcoholic potash, the air being excluded as far as possible, a little phenolphthalein is added, the solution neutralised with acetic acid, and stirred into a boiling solution of 3 grms. of lead acetate in 200 cc. of water. The precipitate is washed with boiling water, extracted with ether, the extract after shaking with dilute hydrochloric acid and repeated washing with water, is made up to 200 cc., 50 cc. are then taken out, the ether almost entirely evaporated, 50 cc. of pure alcohol added and the solution titrated with decinormal sodium carbonate, using phenolphthalein as indicator. 1 cc. of soda solution = 0.0282 gm. of oleic acid.

A quantity of the ethereal extract containing exactly 0.5 gm. of oleic acid is withdrawn, the ether removed by a stream of carbon dioxide, the residue dissolved in 50 cc. of Hübl's reagent (25 grms. iodine and 30 grms. of mercuric chloride in 1,000 cc. of absolute alcohol), allowed to stand in the dark for 12 hours, 15 cc. of chloroform added and the mixture titrated with decinormal sodium thiosulphate. A blank experiment should be made with Hübl's reagent and chloroform. This method is inapplicable when the quantity of cotton-seed oil is less than 15 per cent. (See also this Journal, 1890, 418.)—S. B. A. A.

## New Books.

**PRINCIPLES OF GENERAL ORGANIC CHEMISTRY.** By PROF. E. HJELT. Translated from the Author's German edition of the original work by J. Bishop Tingle, Ph.D., F.C.S., Assistant in the Laboratory of the Heriot-Watt College, Edinburgh. London: Longmans, Green, and Co. New York: 15, East 16th Street. 1890.

SMALL 8vo. volume, bound in cloth, price 6s. 6d. It contains Translator's and Author's Prefaces, Table of Contents, 213 pages of subject-matter, and an alphabetical index. The text is divided into three parts, Part I. dealing with "The Composition, Constitution, and Classification of Organic Compounds"; Part II. with "The Physical Properties of Organic Compounds"; and Part III. with "The General Behaviour of Organic Compounds."

It is stated by the translator that "No similar work exists in English." In Part III., the reactions described are in all cases arranged according to the results; dehydration processes, for example, being all classed together. The work may be briefly defined as a condensed account of the present condition of the theory of Organic Chemistry, more especially designed "as a supplement to, rather than a substitute for ordinary text-books."

**THE ORGANIC ANALYSIS OF POTABLE WATERS.** By J. A. BLAIR, M.B., D.Sc., &c. London: J. and A. Churchill, 11, New Burlington Street. 1890.

THIS little work (8vo., bound in cloth) has for its object the brief practical description of the leading processes for the analysis of potable waters, together with a collection of results obtained by the author in the use of them. The various analytical processes are considered in the following order:—

I. The Albuminoid Ammonia and Oxygen Processes, and then some considerations in reference to the analyses of waters by both methods.

II. The Oxygen Process at 100° C.

III. The Estimation of the Organic Nitrogen by the Sulphuric Acid Process.

IV. The estimation of the Organic Carbon by the Sulphuric Acid and Permanganate Process.

The little work is thus divided into four parts, and in an Appendix sub-divided into groups A, B, C, D and E, is described the preparation of the various solutions required in carrying out the analytical methods described. Thus A.—Solutions for Albuminoid Ammonia. Process B.—Solutions for Oxygen Process at ordinary temperatures. C.—Solutions for Oxygen process at 100° C. D.—Estimation of Nitrates by Arsenious Acid. E.—Solutions for the Sulphuric Acid and Permanganate Process for Organic Carbon.

The text covers 118 pages and the price of the book is 3s. 6d.

**CHEMISCH-TECHNISCHES REPERTORIUM. ÜBERSICHTLICH GEORDNETE MITTHEILUNGEN DER NEUESTEN ERFINDUNGEN, FORTSCHRITTE UND VERBESSERUNGEN AUF DEM GEBIETE DES TECHNISCHEN UND INDUSTRIELLEN CHEMIE MIT HINWEIS AUF MASCHINEN, APPARATE UND LITERATUR.** Herausgegeben von DR. EMIL JACOBSEN. 1889. *Erstes Halbjahr. Zweite Hälfte.* Berlin: R. Gaertner's Verlagsbuchhandlung. Hermann Heyfelder, S.W. Schönebergerstrasse 26. London: H. Grevel and Co., 33, King Street, Covent Garden.

OCTAVO volume in paper cover; the second issue for the first half year of 1889. It contains 171 pages of subject matter, copiously illustrated with wood engravings. In the text the following subjects are treated of:—Foodstuffs and Confections; Paper; Photography; By-products of various kinds; Residual Matters; Manures; Disinfection and Sanitation; Soap; Explosives, &c. Preparation and Purification of Chemicals; Chemical Analysis; Apparatus; Machinery; Electro-technology; Technology of Heat; Appendix; Adulterations of Trade Products, &c. New Books; Alphabetical Index.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

#### RUSSIA.

##### *Regulations respecting Tare Allowance.*

Mr. Audley Gosling, Her Majesty's Chargé d'Affaires at St. Petersburg, in a despatch to the Foreign Office, dated the 23rd July, transmits translation of some new Custom house regulations respecting the allowance for tare on certain wrappers and packings in calculating the duties on imported goods. This translation reads as follows:—

All imported goods specified in the established table of allowance for tare and brought to Russia in wrappers, packing, &c., are generally cleared according to the weight that shall appear after deducting from their gross weight the percentage allowance of tare fixed by the table.

The net weight of these goods is, however, subject to verification (1) when the Customs officers shall have reason to doubt the applicability to certain goods of the proportion of tare allowed under the Table; (2) when the excessive weight of the tare shall be evident before the presentation by an importer to the Customs of the invoice of his goods; but the Customs may refuse to verify the tare if the board of a Custom house shall determine that its verification in any given case would be attended with special difficulties, danger, or injury to the health of the examining Customs officer.

No allowance for tare is made for internal wrappers, &c. which are not destined for preserving goods against injury when in transit, and which are made over to a purchaser together with the goods. Exception to this rule is afforded by the packing cases, &c. indicated under the Customs tariff as being liable to duty according to the materials of which they are made.

Paper wrappers in which woven and other stuffs are enveloped, boards and pasteboard sheets and rounds on which are wound tissues, ribbons, lace, and other goods, are not taken into account at the computation of duty, for which purpose the weight is deducted from the gross weight of the goods. In order to ascertain the weight of such packages it is necessary to weigh only a few of them if the packing be of a uniform character.

In addition to the allowance of tare made on chemicals, drugs, and cosmetics imported in glass, earthenware, and metal vessels placed in cases filled with sawdust, a further tare allowance of 10 per cent. is made on such cases with sawdust.

On all goods imported in vessels, wrappers, earboard boxes, &c. enclosed in an additional outside case, and the duty on which is fixed under the tariff on the gross weight, the duty shall be determined on the gross weight of the goods with their interior packing alone, *i.e.*, exclusive of the additional outside case or packing.—*Board of Trade Journal.*

#### SPAIN.

##### *Exemption from Import Duty of Sulphate of Copper.*

According to a despatch, dated the 2nd July, which has been received at the Foreign Office from Mr. W. A. C. Barrington, Her Majesty's Chargé d'Affaires at Madrid, the Madrid *Official Gazette* publishes a law of the Spanish Government providing that sulphate of copper may be imported into Spain free of duty, irrespective of the use to which it may be destined.—*Ibid.*

#### SERVIA.

##### *New Explosives Law.*

The *Moniteur Belge* says that the Servian law which authorises the Government to manufacture *en régie* powder, dynamite, and all other explosive materials, came into force on the 17th (29th) May last.

The Department of Finance has just published a circular recalling the fact that these products will have to pay on entry into Servia, besides the Customs duties in force, the following monopoly taxes:—

a. Dynamite and any other explosive material intended for trade will pay 1 franc per kilogramme.

Dynamite intended for such industrial undertakings as have legally acquired a privilege for the importation, machines and instruments necessary for them, will only pay 60 centimes per kilogramme.

b. Cartridges for all kinds of guns will pay 1 franc per hundred.

c. Revolver cartridges will pay 50 centimes per hundred.

d. All kinds of fuses and fireworks will pay 50 centimes per kilogramme of their gross weight.

Caps and empty cartridges will pay no monopoly tax.—*Ibid.*

#### NEW SOUTH WALES.

##### Customs Tariff.

The following is a statement of the rates of duty levied under the Customs tariff of New South Wales on certain articles imported into that colony:—

Articles.	Rates of Duty.		
		£	s. d.

—*Ibid.*

#### EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

##### SPANISH COLONIES.

##### Pumice-Stone from the Canaries.

An important mine of pumice-stone exists on the Teneriffe Peak, of which the working was only started in 1888. The stone is found in that part of the peak called the "Canadas," at about 2,000 ft. above sea-level, which has an area of some 6,000 hectares, out of the middle of which rises the highest part of the peak. The Russian Consul at St. Croix bought this property of the Spanish Government in con-

sideration of an annual payment for the pumice-stone working. The Russian Consul has associated himself with a Belgian, and they, under the firm styled "Aguilar and Valcke," commenced operations in 1888, but it was only last year exportation was really started. At the Paris Exhibition this stone obtained a silver medal, and, in view of the requirements of England, France, and America, it may develop into a trade of great importance before many years. So far the Lipari Islands have practically furnished the world's supply of this product, exporting about 100,000 tons per annum. The Teneriffe stone is of excellent quality, and its extraction being a much more simple matter than in the Lipari Islands, it follows that the price is much less. More capital will, however, be wanted to extend the working operations.—*Chemist and Druggist.*

##### INDUSTRIAL ENTERPRISE IN BISCAY.

Her Majesty's Consul at Bilbao states that it is very difficult to point out what articles of commerce would be most in demand for a profitable market in this district; but as capital is abundant, and the present tendency of local capitalists is to implant industrial centres in the country, it may be safely stated that judicious projects of any kind would meet with ready support and aid, if undertaken by responsible and intelligent persons.

The construction of broad and narrow gauge railways continues for the purpose of putting Bilbao in direct communication with all places from which it is expected traffic would result. Among those worth mentioning is an important narrow gauge line now in course of construction between Bilbao and the provinces of Asturias, for the purpose of transporting coal to Bilbao from the mining districts of Asturias and Palencia. The length of this railway would exceed 200 kiloms. (110 miles), and its cost is estimated at 640,000*l.* It is apprehended it would convey from 200,000 tons to 400,000 tons of coal for the annual requirements of Bilbao.

Other industries are also in course of development in the province, such as paper, chemical, and arms manufactures.

The works for the new exterior port, designed and under construction by the eminent and indefatigable engineer-in-chief, Señor Churrua, are proceeding satisfactorily; and it is confidently stated that within eight years the breakwater will be sufficiently advanced to enable vessels to take advantage of its shelter, although its completion will probably not be effected for ten years.—(*No. 733, Foreign Office Annual Series.*)

##### THE SUPPLY OF COPPER FROM CHILI.

A report just issued by the Foreign Office from Vice-Consul Beazley, Caldera, contains several useful statements respecting the copper-mining industry of Chili. That gentleman states that the disastrous termination of the copper syndicate naturally affected the district very considerably, but before the full effects of the breakdown were experienced the price of copper again rose, and the present outlook is very encouraging. The Vice-Consul states that as long as the price of copper keeps above 4*l.* mining and the production of bar pay very well. That statement is one which may be commended to the careful consideration of those who contend that the present prices will not tend to cause an augmented production. The Vice-Consul goes on to state that the province has for many years laboured under the disadvantage of a monopoly in mining matters. One firm has managed to "stifle all competition;" but latterly a successful rival has appeared upon the scene, and, having established a powerful agency at Copiapo, is paying a fair price for metals, thereby producing a favourable reaction in business. Another disadvantage is the poverty of the mine owners, whose want of capital prevents the proper opening up of the rich mineral deposits of the country. There is, however, now some prospect of European capital being more largely invested, in addition to which the proposed construction of the Trans-Andine railway from Tinnogasta to Caldera seems certain to open up the mineral districts very advantageously. The Vice-Consul says that although the exports of bar copper have

fallen off considerably, there is a stock of 1,500 tons on hand ready for shipment at any moment. That was the case, at all events, on March 29th, when the report in question was written. This fact, also, is worthy of being noticed by the "bulls" of copper prices here. Another fact calculated to encourage the production of copper is, that all machinery is now admitted into Chili free of duty. With regard to the disaster which occurred early this year at the Copiapo Mines, the Vice-Consul states that the shaft has been reopened, and the mine will soon be in a better state than ever. The smelting works of Edwards and Co. are also again in full operation, and it is added "the production of 10 months of copper bar is accumulated in the establishment." It is possible that this is the stock already mentioned, but the point is not clearly brought out in the report. Another large concern which had been suspended owing to financial difficulties had resumed work under very favourable auspices, and on a sound basis. The general inference from these various statements is that the production of copper in Chili is being more actively carried on than for some years past, and that we are pretty sure to have larger shipments of bars thence so long as the price is over 47*l.* in the London market.—*Ironmonger.*

#### TUNISIAN PHOSPHATES OF LIME.

The following is an extract from a report by the Belgian Consul at Tunis, dated the 29th June last:—

The Mines Department of the Regency of Tunis has recently discovered the existence of beds of phosphates of lime in the mountainous region to the west of Gafsa, extending over a surface of about 50 kilometres.

The works recently undertaken have conclusively established the existence of phosphates in the regions of Djebel Limra, Seldja, and Stah, to the west of Gafsa, in large deposits, the workable thickness of which varies from 8 to 12 metres, over an extent of 50 kilometres. Analyses have shown that these deposits contain about 60 per cent. of tribasic phosphate, increased by about 3 to 5 per cent. by the washings. The total quantity of phosphates in this region may therefore be estimated at about six million tons, or about five million tons of washed ore, having a strength of at least 62 per cent. of tribasic phosphate of lime.

Other less important deposits are found in the mountains of Djebel Jellabia, Schib, and Refsa, to the south of Gafsa. This region is devoid of water, while to the west, for Limra, Seldja, and Stah, the River Selja supplies the water requisite for the preparation of the ore.

According to information obtained at Tunis, phosphates are worth about 60 francs (2*l.* 8*s.*) per ton. The working of the deposits in question, to the west of Gafsa, would require the construction of a railway connecting them *via* Gafsa to the nearest sea-port, called Skira. If this railway were constructed, the working of the phosphates, after deducting the expenses of extraction, washing, grinding, carriage, &c. would give a net profit of about 10 francs (8*s.*) per ton. The average annual extraction possible would reach 100,000 tons.—*Board of Trade Journal.*

#### FRANCE.

##### *The coming Tariff Revision.*

The summary of the answers given by French chambers and syndicates of commerce to the question issued by order of the Government, asking them to state their views on the approaching expiration of the commercial treaties (the *Chemist and Druggist*, April 19), has recently been issued. It is remarkable, inasmuch as it shows that, however strong the current of protectionism may be in Parliament, it is tempered amongst the manufacturers and merchants by a lively sense of the advantages of moderation.

#### *Chemicals.*

As regards the chemical trade, Lyons, Paris, and Calais are unanimous in advocating free trade in raw materials required for the manufacture of chemicals. All chemicals, they maintain, used in the production of textiles should be imported at low rates, because high duties would be prejudicial to the industries in which such materials are used.

If existing rates are to be changed, they should be reduced rather than increased. If increased, the new charge can only be compensated by export drawbacks, which are not easily applied, and necessarily lead to fraud.

The duties on soda, salts, acids, and methyl-alcohol should be reduced, and free import be allowed in favour of agriculture to pyrites, phosphates, nitrate of potash, sulphate of ammonia, and chloride of potash.

All produce obtained from coal-tar by distillation should remain free from duty, viz., oils and essences, benzene, benzol, naphthalin, &c.; but chemicals obtained from the products of the distillation of coal-tar, such as nitrobenzene, nitro-toluene, aniline, &c. should be charged at the rate of 15 frs. per 100 kilos., or about 5 to 6 per cent. *ad valorem.*

All colouring matters derived from coal-tar should be allowed to enter at a reduction of duty of 50 per cent.

On certain articles of interest to British trade the demands of French makers are protective. Marseilles, Nancy, and Avesnes want an additional duty on caustic soda. Paris would be content with the duty of 8 frs. levied under the present general tariff. But the Syndical Chamber of Paris Dyers and Cleaners advocates a lower charge of 3 frs. and 5 frs. per 100 kilos. in the minimum and maximum tariffs respectively. Dieppe asks for a duty of 1 fr. 50 c. on nitrates of potash and soda; but Granville, Nantes, Orleans, Clermont Ferrand, and others would keep nitrate of soda on the free list, and Paris thinks that a new duty would have to be compensated by a drawback.

Sulphate of copper now pays a duty of 3 frs. per 100 kilos. It is in great demand for dressing vines. The Chamber of Le Mans would raise the tariff, and the Syndical Chamber of Chemical Industries of Paris wants an increase of 65 per cent., but the Syndical Chamber of Dyers and Cleaners claims entire freedom for the article. Calais dyers object to any imposition of duty on aniline.

Paris wishes to put oxalic acid into the list of free imports; Arras, Marseilles, and Nîmes that the duty of 10 frs. on stearic acid should be increased by 10 to 50 per cent. Vienne and Paris propose a duty of 16 frs. per 100 kilos. The dyers of Paris ask for the repeal of the present duty of 10 frs. on chromate of potash, and the suppression of the duty on glycerin. But the merchant brokers of Paris would only admit raw glycerin free, charging 12 frs. to 15 frs. per 100 kilos. on distilled and dynamite glycerin.—*Chemist and Druggist.*

#### GUATEMALA.

##### *The Drug Trade.*

This Central American Republic of Guatemala had a prosperous year in 1889. Its trade increased considerably, and the imports of drugs alone rose from 15,171*l.* in 1888 to 20,155*l.* The drugs mostly come from the United States. The prosperity of the country is ascribed to the advance in the price of coffee, the principal product. The result of the participation of Guatemala in the Paris Exhibition is that the importations from France have more than doubled.—*Ibid.*

#### JAPAN.

##### *Drugs in Yokohama.*

The importation of drugs and chemicals into Yokohama is an increasing trade, large quantities of chemicals being imported for manufacturing purposes, such as paper and match making, glassworks, and other industries.

The Japanese Government are themselves manufacturers of caustic and other sodas, and of sulphuric acid, which is shipped in considerable amounts to the China market, or sold to private Japanese dealers.

Medicines for pharmaceutical purposes are also made on a large scale at Japanese establishments generally reported to be furnished with Government loans. Some importers complain of the continual difficulties, almost prohibitory, raised in regard to the sale of foreign drugs and medicines, these being constantly rejected by the Government analysts,

as not being up to the standard of the Japanese Pharmacopœia; and it appears, from a recent Government notification to Japanese traders, that this condition will in future be strictly enforced. The standard is higher than that of England, and necessitates the preparations submitted to the test being chemically or absolutely pure and free from inherent impurity, such as bismuth without a trace of arsenic. Under the Japanese Pharmacopœia, iodide of potassium is required to be 97 per cent. pure; in the British it is 95 per cent. This staple article, when pure, turns a yellow colour; but it is then apt to be rejected by the trader. The whole question, being of great importance to Japanese consumers and foreign importers, is entitled to earnest attention.

The imports of medicinal drugs and chemicals into Yokohama in 1889 were valued at 106,559*l.*, against 129,914*l.* in 1888.—*Ibid.*

### MISCELLANEOUS TRADE NOTICES.

#### BANANA PAPER.

The *South American Journal* for the 12th July has the following note:—

A new factor is entering the papermakers' market. It has been proved that the banana plant contains a greater quantity of pure fibre than any of the other numerous vegetable products used for the manufacture of paper. During the first 12 months of its vegetation the plant only produces a single bunch of fruit, after which it dies; but from its roots four to 10 young plants spring up. The adaptation of the plant to commercial purposes will, it is anticipated, revolutionise the paper material market, and largely affect the industry. The plant is easy of cultivation, and has long since been recognised by the wandering tribes in Central America as yielding many useful adjuncts to every-day domestic requirements.

#### THE PROGRESS OF WYOMING.

The following is an extract from *Bradstreet's* for the 5th July:—

In mineral wealth Wyoming undoubtedly excels. Coal mining has so far received the most attention. Coal is found in every county, varying from 2 to 40 ft. in thickness. The total production in 1888 was 1,512,936 short tons, worth at the mines 4,538,808 *dols.* One-third of this amount was expended for labour. The number of miners engaged was 1,527, who received at the rate of 90 cents to 1·10 *dols.* a ton for mining. The Union Pacific railroad has done the greater part of this work, monopolising it previous to 1886, but since then it has given outsiders a chance, and they have opened and developed a number of mines.

The soda deposits of the territory are of special interest, for soda has not hitherto been a natural product of the United States. The salt cake of commerce is produced in the eastern States at a few places where salt is cheap and sulphuric acid can be made as a by-product; but the larger amount is imported from England, where it is manufactured from common salt by treating with sulphuric acid and roasting. In Wyoming all that has to be done is to dig it out and dry it; and the territorial geologist says the deposits will amount to 52,000,000 tons. Last year we imported about 150,000 tons of carbonate of soda (including sal soda and soda ash), valued at 2,900,827 *dols.*, and in addition bicarbonate of soda worth 19,912 *dols.*, and caustic soda to the value of 1,300,851 *dols.*

It is further said that Wyoming has iron ores of higher grade and purity than those found in Alabama, abundance of limestone to flux them, and, at easy distances, producing oil wells ready to supply fuel for steel-making or other manufactures. Tin also gives great promise.

#### CHEMICALS IN JAPAN.

Drugs and chemicals are gradually forming a more important feature in the Japanese import trade. Large quantities of chemicals are being imported for manufacturing purposes, such as paper and match making, glass works, and other industries. They come chiefly from Great Britain, but a considerable portion is of German origin. The Japanese Government are themselves manufacturers of caustic and other sodas, and of sulphuric acid. Medicines for pharmaceutical purposes are also made in Japan on a large scale. Some importers complain of the great difficulties raised in regard to the sale of foreign drugs and medicines, these being constantly rejected by the Government analysts as not being up to the standard of the Japanese pharmacopœia, which is higher than the British.—*Industries.*

#### RUSSIAN COAL PRODUCTION.

The *Russie Commerciale* has recently published some particulars respecting the working of the Russian coal-fields. According to this publication the quantity of coal produced in the different countries is distributed as follows:—England, 166,000,000 tons; United States, 118,000,000 tons; Germany, 76,000,000 tons; France, 21,000,000 tons; Austria-Hungary, 22,000,000 tons; Belgium, 18,000,000 tons; Russia, 5,500,000 tons; and other countries, 5,000,000 tons. According to this, Russia only occupies a very secondary place among coal-producing countries, and yet Russia is the richest country in coal-fields. Rich coal-fields are found in the Governments of Moscow, Riazan, Toula, Poland, Caucasus, and particularly in the basin of the Donetz. Coal-fields which have up to the present remained unworked are found in the Island of Sakhaline, Western Siberia, in the neighbourhood of the Oural, in the Kirghish Steppes, and the plains of Turkestan; but it is particularly the basin of the Donetz which is remarkable for its coal wealth. According to the estimates of Professor Mendeleiev, the surface of the ground occupied by the coal-beds in this province extends over nearly 50,000 square kilometres, or 11,580 square miles. Taking the average figure of 50,000,000 poods (a pood is equivalent to 36 lb. avoirdupois) to the square kilometre, it will be found that the general yield of coal will amount to the total of 1,500,000,000,000 poods, or 21,000,000,000 tons. The entire world, says Professor Mendeleiev, might be supplied during the next 50 years with coal from the Donetz basin. The above remarks apply only to the superficial beds; as regards the others, which are at considerable depth, and which have not yet been worked, they are said to be even of greater richness. The working of coal lying at great depths can only up to the present be considered as an experiment, and the same may be said of the beds situated in the Kirghish Steppes, in the Governments of Tomsk, Caucasus, Turkestan, and the Island of Sakhaline, where the working is in a very elementary state. Coal mining has received a very considerable impetus in Poland, and in the basin of the Donetz. In 1888, Poland yielded 142,000,000 of poods, and the basin of the Donetz, 140,000,000 (2,290,000 tons and 2,258,000 tons respectively). Although the working of coal is rapidly on the increase, the quantity extracted is not sufficient for the requirements of the country, which is obliged to have recourse to foreign importation. In spite of its immense coal-fields, Russia imports annually nearly 107,000,000 poods of coal (1,726,000 tons), of which 85,000,000 poods are supplied by England, 19,000,000 by Germany, and more than 2,000,000 poods by Austria-Hungary. Russia, in addition, consumes enormous quantities of wood for her various industries, and this leads in a great measure to the destruction of her forests, with all its disastrous consequences. In spite of its good qualities, Russian coal cannot compete with foreign coal, even in the southern ports, which are found in proximity to the coal-fields of Donetz. Notwithstanding the increase in the duties on importation of foreign coal at Odessa, Sebastopol, and in the other ports of the Black Sea, English coal is no dearer than Donetz coal, and far from diminishing, its importation has greatly increased.

of recent years. "This proves," says the *Russie Commerciale*, "that the demands of the various industries for coal increase more rapidly than the working of this combustible in Russia, and that the condition of the means of transport is far from satisfactory."—*Journ. Soc. Arts.*

#### THE RUSSIAN NAPHTHA INDUSTRY.

According to a report of the Russian Finance Minister, both the production and export of Baku oil products continue to grow. In the five first months of the present year Russia exported 22,720,000 poods of naphtha, or 7,560,000 poods more than in the corresponding period of 1889. It should, however, be remarked that of this so-called naphtha 17,320,000 poods weight was refined kerosene. Russia itself took 53,150,000 poods of naphtha, 5,200,000 poods of this being refined kerosene and 40,850,000 poods residuals. Upon the completion of the Wladikawkas-Baku railway a further important development of the naphtha trade is expected. Valuable naphtha springs have lately been discovered on Sakhalin Island, and a company has been formed to work them. A representative of the concern is at present in Baku studying the processes of boring for and shipping oil.—*Ironmonger.*

#### GAMBIER AT SINGAPORE.

Referring to an extract from the annual report of the Singapore Botanical Gardens which appeared in the June number of this Journal, pp. 670—671, we are requested to state that, though the attempt to propagate the plant by seed has failed, yet the plants themselves have been transported to this country by means of Wardian cases, and may be seen in full vigour at Kew Gardens, where they only await purchasers to be transferred to any colony with a suitable climate.

#### EXPORTS OF CHEMICALS FROM THE TYNE.

The following chemicals were exported from the Tyne during the month just ended and corresponding month of 1889:—

	1890.	1889.
	Tons.	Tons.
Alkali and soda ash .....	1,267	1,111
Bicarbonate of soda .....	..	14
Bleaching powder .....	2,808	1,736
Artificial manure .....	3,931	2,854
Soda crystals .....	982	1,017
Sulphate of soda .....	42	10
Caustic soda .....	910	..
Other chemicals .....	1,115	1,752
Total .....	11,055	8,554

Making an increase of 29·23 per cent. for the month. The heavy increase in the quantity of bleaching powder exported is owing to makers being unrestricted in their output this year, whereas their make during the previous year was curtailed by the Bleach Association. Bicarbonate of soda is not now manufactured on Tyneside, the production having ceased some months ago.—*Chemist and Druggist.*

#### SULPHUR EXPORTS FROM ITALY.

The official returns show that the gross exports of raw and refined sulphur from Italy, up to the end of May last, amounted to 1,700,106 quintals, in contrast with 1,503,394 quintals in the same five months last year, this being an increase of 196,712 quintals. This export is valued at 11,900,742 lire in 1890, and 10,523,758 lire in 1889, thus showing an advance on the gross value of 1,375,984 lire. The official valuation puts sulphur at 7 lire per quintal. The destination of the exports is given, as presented in the

annexed table, for the first five months of the last three years:—

Exported to	1888.	1889.	1890.	Difference 1890 on 1889.
	Quintals.	Quintals.	Quintals.	
Austria-Hungary .....	64,816	61,191	90,181	+ 28,990
Belgium .....	21,468	45,185	33,991	— 11,194
France .....	397,360	333,203	494,876	+ 71,673
Germany .....	72,772	61,925	60,115	— 1,810
Great Britain .....	193,587	169,787	137,174	— 32,163
Greece .....	64,345	102,935	137,679	+ 34,744
Holland .....	7,223	8,824	6,607	— 2,217
Portugal .....	85,130	106,252	173,121	+ 66,869
Russia .....	18,638	87,157	53,666	— 33,491
Spain .....	50,220	49,166	51,510	+ 2,344
Sweden and Norway ..	4,803	19,097	29,284	+ 10,187
Turkey .....	10,290	25,246	57,269	+ 32,023
North America .....	545,068	410,267	497,293	+ 27,026
Central and South America .....	45,995	7,629	1,686	— 5,943
Other countries .....	10,131	15,230	25,651	+ 10,421
Total .....	1,501,746	1,503,394	1,700,106	+ 196,712

The position of the trade is so clearly shown in the foregoing that there is no need for comment.—*Chemical Trade Journal.*

#### THE GERMAN CEMENT INDUSTRY.

The manufacture of Portland cement has made rapid progress during the last 25 years. In 1865 the industry was in its infancy, and was carried on upon a small scale at Bonn, Stettin, Lünenburg, &c., the manufacturers working under licenses from a Mr. Ashlin, an Englishman, who owned the German patent for the so-called wet process. The manufacture of cement has grown so rapidly that at the present time the annual output is estimated at 10,000,000 barrels, worth 70,000,000 M. The chief seat of the industry is North Germany, in the vicinity of Berlin, Stettin, Hamburg, and Hanover. The export trade has increased from 137,000 kilocentners in 1879 to 1,341,300 kilocentners in 1889. The chief foreign market is the United States, to which destination some 405,000 kilocentners were exported in 1889. Roumania, during the same period, took 211,000; Australia, 171,000; Brazil, 126,000; Chili, 895,000; Japan, 88,500 kilocentners.—*Ironmonger.*

Manures:—				
Guano..... Tons	2,587	..	15,781	..
Bones..... "	2,544	1,760	12,281	9,140
Paraffin..... Cwt.	18,789	33,556	21,911	1,426
Linen rags..... Tons	3,624	3,328	38,401	30,062
Esparto, &c..... "	14,366	17,081	70,297	77,767
Pulp of wood .... "	9,457	14,237	56,559	76,548
Rosin..... Cwt.	115,027	119,957	25,853	37,977
Tallow and stearin .. "	145,893	174,867	186,232	223,276
Tar..... Barrels	15,477	28,615	9,266	18,965
Wood:—				
Hewn..... Loads	274,052	262,912	688,333	585,900
Sawn..... "	921,956	834,605	2,211,998	1,914,144
Staves..... "	21,062	17,101	70,322	82,326
Mahogany..... Tons	2,804	2,967	24,752	25,063
Other articles.... Value £	..	..	886,277	810,777
Total value .....	..	..	5,009,843	4,492,390

Besides the above, drugs to the value of 38,068*l.* were imported, as against 54,262*l.* in 1889.

## EXPORTS OF METALS (OTHER THAN MACHINERY) FOR MONTH ENDED 31ST JULY.

Articles.	Quantities.		Values.	
	1889.	1890.	1889.	1890.
Brass..... Cwt.	9,967	16,774	42,359	50,302
Copper:—				
Unwrought..... "	72,415	80,825	158,331	243,564
Wrought..... "	39,283	21,111	79,189	75,477
Mixed metal .... "	33,856	48,228	80,616	136,348
Hardware..... Value £	..	..	230,693	246,614
Implements..... "	..	..	109,640	116,625
Iron and steel.... Tons	352,695	391,724	2,343,596	2,414,396
Lead..... "	4,130	4,036	58,717	58,186
Plated wares... Value £	..	..	35,736	31,799
Telegraph wires... "	..	..	32,909	56,575
Tin..... Cwt.	11,768	9,325	55,112	45,780
Zinc..... "	17,373	15,957	12,860	11,839
Other articles .. Value £	..	..	77,456	95,964
Total value .....	..	..	3,303,409	4,117,287

## EXPORTS OF DRUGS AND CHEMICALS FOR MONTH ENDED 31ST JULY.

Articles.	Quantities.		Values.	
	1889.	1890.	1889.	1890.
Alkali..... Cwt.	389,222	491,818	104,834	167,342
Bleaching materials .. "	126,848	145,442	46,218	40,055
Chemical manures. Tons	20,915	36,550	142,242	189,686
Medicines..... Value £	..	..	77,659	94,443
Other articles ... "	..	..	241,622	242,615
Total value .....	..	..	612,575	731,441

## EXPORTS OF MISCELLANEOUS ARTICLES FOR MONTH ENDED 31ST JULY.

Articles.	Quantities.		Values.	
	1889.	1890.	1889.	1890.
Gunpowder..... Lb.	957,969	1,189,800	21,619	27,225
Military stores.. Value £	..	..	76,351	133,637
Candles..... Lb.	1,158,809	1,123,400	20,161	22,410
Caoutchouc..... Value £	..	..	100,946	102,327
Cement..... Tons	62,533	54,393	124,763	113,154
Products of coal Value £	..	..	75,254	91,640
Earthenware ... "	..	..	186,281	214,843
Stoneware..... "	..	..	19,284	16,901
Glass:—				
Plate..... Sq. Ft.	276,665	240,151	18,231	15,406
Flint..... Cwt.	10,588	9,496	21,344	22,191
Bottles..... "	87,941	86,878	43,125	41,331
Other kinds.... "	18,977	14,651	12,742	14,028
Leather:—				
Unwrought .... "	11,051	11,123	106,969	101,948
Wrought..... Value £	..	..	31,749	31,913
Seed oil..... Tons	4,881	4,716	108,091	113,364
Floor cloth..... Sq. Yds.	1,435,600	1,441,800	71,674	73,871
Painters' materials Val. £	..	..	139,633	147,007
Paper..... Cwt.	80,281	86,454	147,129	148,615
Rags..... Tons	4,106	5,299	32,946	40,256
Soap..... Cwt.	46,977	52,705	41,863	54,282
Total value .....	..	..	2,751,161	3,143,229

## Monthly Patent List.

\*The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

11,042. J. W. Gooch, C. A. Baker, and W. White. Improvements in electric thermometers and thermographs. July 15.

11,082. J. Whitehead. Improvements in and apparatus for supplying fuel to steam boiler and other furnaces. July 16.

11,246. J. Klein. Improved process and apparatus for cooling liquids by means of air. Complete Specification. July 18.

11,262. W. Robertson and D. J. Macdonald. Improved apparatus for compressing air or other fluid. July 19.

11,529. A. Chapman and S. Vickers, jun. Improvements in evaporating apparatus, specially adapted for the extraction of salt from brine. July 23.

11,686. S. M. Lillie. Improvements in evaporating apparatus. Filed July 25. Date applied for December 26, 1889, being date of application in United States. Complete Specification.

11,714. D. Rylands and R. Morant. Improvements in glass-lined tubing. July 26.

11,747. G. U. Haslam and P. Cornish, jun. An improved method of drying and desiccating wet substance and materials. Complete Specification. July 26.

11,807. W. P. Thompson.—From A. Raps, Germany. Improvements in or appertaining to mercurial pumps. July 28.

11,895. L. Johnstone. Improvements in and connected with rotative furnaces or kilns for treating and recovering waste products from raw or partially raw materials, used more especially, and for example, in the manufacture of cement. July 30.

12,004. L. Menetrel. An improved apparatus for washing, lixiviating, or extracting purposes. July 31.

12,079. C. D. Martin. Improvements in valves for chemical liquids. August 1.

12,260. A. W. Ellis. See Class XVII.

12,325. J. Jackson. Improvements in pressure and vacuum gauges. Complete Specification. August 6.

12,421. D. Bethmont. Improvements in apparatus for generating steam or vaporising liquids. August 8.

12,505. S. Seekendorf. An improved drying apparatus for granular, pasty, and similar material, and press for forming the dried material into cakes. Complete Specification. August 9.

12,535. E. Barlow and R. Cunliffe. Improvements in apparatus for drying, calcining, and evaporating substances or materials. August 11.

12,542. E. Guigon. Improvements relating to the circulation of water in surface condensers. August 11.

12,897. G. A. Hart. An improved construction of kiln for drying moist materials. August 16.

### COMPLETE SPECIFICATIONS ACCEPTED.\*

1889.

12,206. W. Tipping. Apparatus for destructing, drying, and calcining. July 23.

12,410. W. L. Wise.—From P. R. Bedlington. Apparatus for indicating temperature and pressure. August 13.

12,871. C. H. Roeckner, F. L. Roeckner, and R. L. Roeckner. Apparatus for concentrating and evaporating liquids, and burning off organic matter. July 23.

14,958. J. Hodgkinson. Mechanical stokers. July 30.

15,124. R. C. A. Banfield.—From C. Linde. Method and means for refrigerating and drying air. July 30.

15,432. R. Marsden and J. Pickard. Transferred to Class V.

16,099. P. Nezeraux. Centrifugal pumps, compressors, and blowers. August 20.

19,222. E. Theisen. Evaporating apparatus. July 23.

1890.

3279. W. H. Skinner. Heating water and other liquids, and fuel for use therefor. August 20.

6136. J. Klein. Apparatus for condensing, heating, or cooling gases or liquids. July 23.

8499. H. Schulze-Berge and F. Schulze-Berge. Air pumps. August 13.

9312. G. Horner. Surface condensers. July 23.

9326. J. O. Woods. Vaporisers. July 23.

9379. W. B. Bull. Means for purifying liquids for prevention of boiler incrustation, ageing liquors, &c. August 13.

9554. L. H. A. W. Sack. Apparatus for automatically drawing off viscous substances. July 30.

9941. R. Haddan.—From E. Passburg. Method and apparatus for drying aqueous matter. Aug. 6.

10,133. P. Abrahamson. Oven and other fire-chamber doors. August 20.

10,398. L. P. Cohen and E. Hermann. Furnaces. August 13.

10,524. T. Gaunt and E. H. Chapp. Evaporating apparatus. August 13.

### II.—FUEL, GAS, AND LIGHT.

#### APPLICATIONS.

11,079. J. Laing. Improvements in the apparatus for destructive distillation of mineral oils. July 16.

11,091. W. R. Hutton. Improvements in apparatus for making coke from coal, and obtaining tar and ammoniacal water and mixed gases therefrom. July 16.

11,106. J. E. Bott, W. Mortimore, and F. H. Lindley. Improvements in gas producers. July 16.

11,195. W. W. Staveley. Improvement in the treatment of crude blast-furnace or coke-oven oils, and application of the oils so treated or produced. July 18.

11,239. W. H. Buckland and G. Myers. Improvements in the composition and manufacture of fuel from coal dust and similar material. July 18.

11,424. G. F. Priestly. Automatic charging and discharging gas retorts. July 22.

11,452. J. Hall. Improvements in the manufacture of coke or in the coking of coal. July 22.

11,514. W. Laezy. Improvements in the manufacture of artificial fuel. July 23.

11,581. F. J. Rowan and H. Armour. Improvements in and connected with retorts for distilling shale or other oil-yielding minerals. July 24.

11,740. S. H. Smith. Improvements in gas-producer furnaces. July 26.

11,757. J. Laing. Improvements in the apparatus for destructive distillation of mineral oils. July 28.

11,784. J. W. C. C. Schirm. Improvements in the method for producing intense light by magnesium or by other glowing materials. Complete Specification. July 28.

12,016. W. Foulis. Improvements in the stirring and drawing of the charge in gas retorts, and in the apparatus employed therefor. July 31.

12,036. I. Lilley and G. H. Hopkins. Improvements in the manufacture of "patent" or compressed fuel, and in machinery or apparatus therefor. Complete Specification. August 1.

12,134. F. V. Hadow. An improvement in treatment of coal for the production of artificial fuel. August 2.

12,217. E. Andrews and C. Miller. Economising, saving, and increasing the heat of fuel, such as coal, coke, wood, turf, and other fuel for heating and drying purposes. August 5.

12,282. C. C. Sykes and G. Blamires. Improvements in apparatus for removing watery vapour from illuminating gas. August 6.

12,580. C. W. Bartholomew and J. Oxley. New or improved apparatus for drawing coke from coke ovens. August 12.

12,638. G. Frank. Improvements in compressed fuel. August 12.

12,639. R. Schimper. Improvements in the manufacture of artificial fuel. August 12.

12,860. J. T. Key. Improvements in the process of and apparatus for manufacturing gas and for the utilisation of the same. Complete Specification. August 16.

12,895. A. M. Hay. Improvements in the process and apparatus for producing oil water-gas. August 16.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

11,624. F. J. Jones. Manufacture of illuminating gas. August 20.

12,266. B. H. Thwaite. Method and apparatus for producing water-gas. August 13.

13,016. J. Dewar and B. Redwood. Distillation of mineral oils, &c., and apparatus therefor. August 20.

14,990. J. R. Wigham. Improving the illuminating power of lighthouses and other places. July 30.

15,409. J. Somerville and S. Cutter. Apparatus for charging and drawing gas retorts. August 6.

15,797. J. R. Paisley. Apparatus for manufacture of water-gas. August 13.

1890.

9733. S. Pitt.—From E. J. Jerzmanowski. Manufacture of illuminating gas. August 6.

#### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

##### APPLICATIONS.

10,976. T. H. Davis and A. H. Davis. See Class XIII.

11,079. J. Laing. See Class II.

11,757. J. Laing. See Class II.

12,415. E. Boernstein and S. Kleeman. Improvements in the treatment of commercial xylidine for effecting the separation of its various isomeric xylidines. August 8.

#### IV.—COLOURING MATTERS AND DYES.

##### APPLICATIONS.

11,530. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in and connected with the manufacture of artificial indigo. July 23.

11,548. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, France. Manufacture of azo-colouring matters derived from azoxyamines. July 23.

11,802. L. Scholvién and L. F. Riedel. Improvements in the manufacture of phenyldimethylpyrazoline. July 28.

12,356. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in the manufacture and production of colouring matters from dihydroxybenzoic acid. August 7.

12,369. Brooke, Simpson, and Spiller, Limited, and W. S. Simpson. Improvements in the manufacture of blue-black and other azo-colouring matters. August 7.

12,386. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in and relating to the production and manufacture of new materials for the preparation of dyestuffs. August 7.

12,550. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in the manufacture and production of new diphenyl derivatives and a new base for use in the preparation of dyestuffs. August 11.

12,715. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture and production of new derivatives of alizarine and its analogues. August 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

12,784. O. Imray.—From the Société Anonyme des Matières Colorantes, &c. Colouring matters derived from paratoluidine,  $\alpha$ -metaxylidine, pseudo-eumidine, and mesidine, with tetramethyldiamidobenzhydrol. August 20.

13,217. H. H. Lake.—From A. Leonardt and Co. Colouring matters. August 20.

13,665. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Production of colouring matters. August 6.

14,207. The Clayton Aniline Co., Limited, P. Brunner, and J. Hall. Production of colouring matters. August 6.

14,230. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture and application of colouring matters. August 6.

16,448. J. Dawson. Manufacture of a grey basic colouring matter soluble in water. August 13.

16,699. S. Pitt.—From L. Casella and Co. Preparation of amidonaphtholsulphonic acid, and of colouring matters therefrom. August 20.

1890.

8389. A. Remy, R. Kramer, and W. Herking. Manufacture of colouring matters. August 6.

#### V.—TEXTILES, COTTON, WOOL, SILK, Etc.

##### APPLICATIONS.

11,005. A. Gratz and B. Gratz. Improvement in the process of treating textile fabrics, and manufacturing bagging from jute butts. Complete Specification. July 15.

11,094. F. Lechner. Improvements in or relating to the manufacture of artificial silk and thread, and in apparatus therefor. July 16.

- 11,986. F. T. Kuott. *See Class XXI.*  
 12,576. J. Sutcliffe and J. Greenwood. An improvement in the treatment of yarn for weaving. August 12.  
 12,689. K. Trobach and G. J. Bruch. *See Class VI.*

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

12,626. G. W. Robertson, D. Black, and J. McGlashan. Treatment of vegetable fibrous material, and apparatus therefor. July 23.

12,975. A. Deru. Process and apparatus for automatically drying and purifying wool and other textiles. July 30.

15,432. R. Marsden and J. Pickard. Condensers for slivers of wool or other fibre. August 6.

15,135. J. E. Richardson. Manufacture of carpets, matting, twine, &c. from esparto grass. July 30.

16,258. J. Schofield. Production of yarn, and machinery therefor. August 20.

1890.

7390. J. Longmore and W. L. Watson. Decortication of rhea, jute, and other fibrous vegetable stems. July 23.

11,005. A. Gratz and B. Gratz. Improvement in the process of treating textile fabrics, and manufacturing bagging from jute butts. August 20.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

## APPLICATIONS.

11,044. M. L. W. Martinot. Improvements in apparatus for washing or bleaching. Complete Specification. July 15.

11,100. A. H. Wardle. Improvements in machinery for dyeing hanks of silk and other yarn. July 16.

11,372. A. Mitscherlich. New process of sizing paper. July 21.

11,580. W. Marriott. Improved mordant for black dyeing. July 24.

11,765. A. Goldthorp. An improved method of dyeing wool, cotton, or any other fibrous substance, in its raw or manufactured state, such as tops, slubbing, yarn on cops or bobbins, yarn in hanks, and cloth in the piece. July 28.

11,873. H. H. Lake.—From The L. Weldon Dyeing-Machine Co., United States. Improvements in yarn-dyeing machines. Complete Specification. July 29.

12,379. H. H. Mott and J. Perry. Improvements in the manufacture of decorative wall papers. August 7.

12,403. W. H. Claus. The production of new blue colouring matters on woollen fibre. August 8.

12,689. K. Trobach and G. J. Bruch. A new or improved process of obtaining and bleaching vegetable fibres. Complete Specification. August 13.

12,900. T. Strahan. Improvements in the process of colouring or decorating paper and other fabrics for wall coverings, and for other purposes. August 16.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

14,246. A. Ashworth. Production of an indigo vat. July 30.

11,938. R. Leigh. Sizes and methods for fixing colours in printing and staining paper, &c. July 23.

15,671. L. Schreiner. Improvements in bleaching and methods for producing bleaching agents. July 30.

16,156. T. Holliday. Producing azo-colours on or in cotton or other textile. August 20.

16,368. A. Greg. Bleaching wood bobbins, reels, &c. August 13.

1890.

11,044. M. L. W. Martinot. Improvements in apparatus for washing or bleaching. August 20.

## VII.—ACIDS, ALKALIS, AND SALTS.

## APPLICATIONS.

11,020. J. R. Wylde, M. J. Hammill, and H. Auer. Improvements in or appertaining to the manufacture of carbonate of strontium. July 15.

11,296. A. G. Haddock and J. Leith. Improvements in the manufacture of alkaline carbonates and by-products, and in arrangement of plant therefor. July 19.

11,529. A. Chapman and S. Vickers. *See Class I.*

11,545. F. M. Lyte and J. G. Tatters. Improvement in the conversion of hard burnt into soft burnt magnesia. July 23.

11,605. P. Kestner. Improvements in the manufacture or production of salts of barium. July 24.

11,638. T. Elliot. An improved process for producing sulphate of calcium. July 25.

11,699. G. Nahsen. *See Class XI.*

11,979. W. B. Giles, F. G. A. Roberts, and A. Boake. Improvements in the production of acid sulphates. July 31.

12,251. M. Netto. Improvements in and relating to the manufacture of sulphide of sodium, and to apparatus therefor. August 5.

12,273. G. E. Davis and A. R. Davis. Improvements in the preparation of sulphurous acid. August 6.

12,274. G. E. Davis and A. R. Davis. The preparation of monohydrated sulphuric acid. August 6.

12,275. G. E. Davis and A. R. Davis. The preparation of anhydrous sulphuric acid. August 6.

12,641. C. T. J. Vautin. An improved process and means for producing the generation of chlorine gas for the chlorination of gold or other ores. Complete Specification. August 12.

12,661. R. Dempster and J. Dempster. Improvements in apparatus connected with the manufacture of sulphate of ammonia. August 13.

12,670. J. Simpson. Improvements in the treatment of certain minerals or slag containing phosphate of lime, for the purpose of obtaining the latter in a concentrated form, with or without the production of alkali as a by-product, and in apparatus therefor. August 13.

12,717. H. B. Yardley. The utilisation of gases which form insoluble or partially insoluble precipitates. August 14.

12,782. J. Anderson. An improved method of preserving alkaline sulphide and similar liquors. August 14.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

13,697. H. Grüneberg, H. Fleming, and W. Siepermann. Preparation of cyanogen alkalis, and apparatus therefor. July 30.

15,531. W. L. Wise.—From Solvay and Co. Apparatus for producing gaseous hydrochloric acid. August 13.

15,649. F. Bale. Obtaining ammonia, chlorine, and hydrochloric acid from ammonium chloride, and apparatus therefor. August 6.

15,655. J. Grossmann. Manufacture of nitrite of soda. August 13.

16,213. W. Shapleigh. Producing chloride of lead. August 13.

1890.

312. J. Gimson and Challinor. Appliance for supporting china while being fired. August 20.

9670. J. C. Steele. Packing chloride of lime, &c. July 30.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

### APPLICATIONS.

11,279. Gibbons, Hinton, and Co. Improvements in the manufacture of ornamental tiles, chromo, relieve, and figured tiles. July 19.

11,560. A. Schaaf. Improvements in drying stoves for bricks, ceramic materials, and such like. Complete Specification. July 23.

11,651. D. Rylands and A. Husselbee. Improvements in the manufacture of glass tubing. July 25.

12,212. G. F. Chance and Chance Bros. and Co., Lim. Improvements in lears for annealing sheets of glass. August 5.

12,506. T. Webster, sen., and T. Webster, jun. An improved process for making articles of earthenware, such as flower pots, preserve jars, cups, and similar goods of improved form either whole or in section. August 9.

12,665. T. Furnival, S. Furnival, A. Furnival, and C. Toft. An improved method of decorating pottery and glass ware. August 13.

12,794. G. A. Marsden. Improved modes of producing novel effects in the decoration of ceramic ware. August 15.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

13,262. H. Dudley-Cooper and J. Selby. Connections for glass or porcelain lined metal tubing. August 20.

14,653. A. J. Clay. Glazed bricks and tiles. July 23.

15,801. Sir H. Doulton and J. Slater. Decorating china, &c. August 13.

16,285. R. B. Baugh. Improvements in the brushing-on process in the manufacture of decorated enamelled metal or glass plates, &c. August 20.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

### APPLICATIONS.

10,918. N. W. Curtis and A. E. Carey. Improvements in machinery or apparatus for crushing, mixing, grinding, and delivering materials for the manufacture of cement. July 14.

10,962. R. G. de Vasson and The Société dite La Suberine. Improvements in the manufacture of plastic compounds for building and other purposes, and in apparatus therefor. July 14.

11,115. J. Thomlinson. Improvements in the manufacture of cement. July 16.

11,245. S. McDougall. Improvements in blocks, tiles, or the like for pavements, sidewalks, floors, platforms, steps, or similar places, and in the manufacture thereof. July 18.

11,443. A. Buecher. An improved process for manufacturing light bricks for building purposes from gypsum, &c. Complete Specification. July 22.

11,479. F. Oschwald. New or improved building material. July 22.

11,796. E. Dupont. Manufacture of compound plates or slabs of cement, plaster, and like material. July 28.

11,839. W. L. Wise.—From Ottweiler Chamotte and Thonwaarenfabriken, vormals L. Jochum, Germany. Manufacture of coke bricks, coke plates, and similar articles. July 29.

11,895. L. Johnstone. See Class I.

12,431. J. S. Palmer. Improvements in the manufacture and production of compounds or materials for covering walls, floors, ceilings, or other surfaces, or for architectural moulding, or other analogous purposes. August 8.

12,607. C. George. Improvements in the manufacture of artificial stone. August 12.

12,640. F. F. von Aimbach. A new or improved process for the production of stony polychrome decorations. August 12.

12,738. J. Bowing. Improvements in the means of drying insoluble substances in a divided state, more especially applicable to the manufacture of Portland and similar cements. August 14.

12,894. W. R. Taylor. Improvements in the manufacture of cement. August 16.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

14,600. J. Cockburn. Manufacturing pavement, &c. of rubber or rubber compounds. July 30.

14,963. H. Stantou. Fire-resisting floors for buildings. July 30.

14,997. A. Bishop. Method of burning lime, and kilns therefor. August 6.

15,115. W. Joy. Improved cement kilns; mills for grinding cement clinker; and apparatus for separating the finer and coarser particles of disintegrated chalk, and ground cement clinker; and treating cement. August 20.

1890.

1356. A. J. Boulton.—From W. Deissner. Manufacture of rough, glazed, and coloured facing stones. August 13.

9239. D. Hart. Improvements in bricks. July 23.

## X.—METALLURGY, MIXING, Etc.

### APPLICATIONS.

10,940. H. A. van Vught. A hardening preparation to harden iron all through, being far superior to all others. July 14.

11,012. A. G. Brookes.—From O. Petit, France. Improvements in converting and refining metals, and in cupolas or apparatus employed therein. July 15.

11,328. G. Hilgenstock and J. Massenez, trading as Hoerder Bergwerks und Hütten Verein. An improved method of separating sulphur from sulphureous pig iron. July 19.

11,550. W. Hornsby.—From C. Raleigh, South Africa. Improvements in extracting gold and silver from ores and other substances containing the same. July 23.

11,606. P. Rogers and J. Player. Improvements in machinery or apparatus for coating metal plates or sheets with tin, lead, or other metals or alloys. July 24.

11,649. A. Jepson. Improvements in the manufacture of iron and steel castings. July 25.

11,690. P. U. Askham and W. Wilson. Improvements in electro-magnetic separators for extracting metal from slag and the like. July 26.

11,790. M. W. Ponder. Improvements in the manufacture of tin and other metal ware, and in apparatus therefor. July 28.

11,841. F. Wicks. Improvements in the process of alloying metals by vapour, and particularly by sublimated aluminium chloride. July 29.

11,851. C. Rabache. Improvements in apparatus for the extraction or reduction of zinc and other metals from ores or compounds. Complete Specification. July 29.

11,868. W. W. Keys. Improvements in and relating to a process of and furnace for treating copper and its alloys. Complete Specification. July 29.

11,877. H. H. Lake.—From La Société Vanzetti Sagramoso and Co., Italy. Improvements relating to the manufacture of steel. July 29.

12,040. J. Pointon. An improved method of dephosphorising iron ore. August 1.

12,045. G. A. Jarvis. A new or improved method of treating steel or iron previous to casting the same. August 1.

12,200. W. Beatson. Recovering tin from waste tinned iron or steel. August 5.

12,234. J. H. Darby. Improvements in or relating to the manufacture or iron from iron sand or fragmentary or other iron ores. August 5.

12,342. J. B. Hannay. Improvements in obtaining silver and other precious metals from ores, and in apparatus therefor. August 7.

12,387. J. Ketcher. Improvements in means or apparatus for extracting by amalgamation precious metals from their ores or materials containing them. August 7.

12,432. T. Parker and A. E. Robinson. Improvements in the manufacture or production of zinc from compounds thereof. August 8.

12,553. I. A. F. Bang and M. C. A. Ruffin. Improved process of and means for the separation of tin from other metals, more particularly from scrap tin plate and used preserve tins. Complete Specification. August 11.

12,624. A. M. Clark.—From W. G. Horgan, United States. Improvements in fluxes or solutions for coating metals with lead. August 12.

12,626. L. Mond. Improvements in the manufacture of nickel. August 12.

12,627. L. Mond. Improvements in nickel plating. Complete Specification. August 12.

12,641. C. T. J. Vautin. See Class VII.

12,666. W. Brazell. An improvement relating to annealing tin andterne plates. August 13.

12,716. S. O. Cowper-Coles. Improvements in the deposition of alloys. August 13.

12,831. E. Zappert.—From C. Searneo, Austria. An improved manufacture of material to be employed in ship-building, and in the manufacture of armour plates, and for other purposes. August 15.

12,836. R. E. Shill. Improvements in apparatus for separating precious metals from ores or materials containing them. August 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

12,033. H. Bessemer, jun. Production of aluminium and apparatus therefor. July 23.

13,277. M. Gledhill. Manufacture of cast metal ingots, &c., and apparatus therefor. July 30.

14,770. E. J. Railton. Gold screening apparatus, August 20.

15,245. E. Grutzner and O. Koehler. Process and apparatus for condensing the metallic vapours produced in zinc furnaces, and furnace applicable in combination with the said apparatus. August 6.

15,552. T. H. Roberts and T. Underhill. Puddling furnaces and appliances connected therewith. July 30.

15,792. L. Grabau. Apparatus for obtaining metals of the alkalis from molten chlorides. August 20.

16,447. C. A. Burghardt. Manufacture of tin plates. August 6.

16,776A. J. B. Abugaray. Universal furnace for fusing and refining metals, alloys, dross, &c., by the dry process or otherwise. July 23.

#### XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

##### APPLICATIONS.

11,065. G. A. Oncken. Improvements relating to the impregnation of organic, fibrous, and cellular matter, by means of an electric current, and apparatus therefor. July 15.

11,187. A. W. Armstrong. Improvements relating to the manufacture of articles by electro-deposition, and to compositions for use in such manufacture. July 17.

11,319. H. Howard. Improvements in apparatus to be used for electric welding. July 19.

11,533. M. G. Farmer. An improved electrolytic apparatus for forming copper ingots. Complete Specification. July 23.

11,601. A. H. Cowles.—From F. W. Matthiessen, United States. A process for obtaining metals in molten condition from their fused oxides by electrical action. July 24.

11,680. M. G. Farmer. An improved apparatus for producing sheets of metal by electro-deposition. Complete Specification. July 25.

11,699. G. Nahsen. Process for obtaining chlorine and bromine by the aid of electricity. Complete Specification. July 26.

11,842. G. L. Anders and J. R. Shearer. Improvements in the deposition of metals by electrolysis. July 29.

12,562. W. O. Stanley. New or improved means or apparatus for generating electricity. August 11.

12,628. H. E. Fowler. Improvements relating to the welding of metals by electricity. Complete Specification. August 12.

12,830. H. H. Lake.—From G. A. Johnson and S. L. Holdrege, United States. Improvements in secondary batteries and electrodes therefor. August 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

7005. A. Schanschieff. Galvanic batteries. July 30.

12,503. F. V. Andersen. Dynamo-electric machines. August 6.

14,871. E. Hopkinson and D. Appleton. Improvements in vessels containing liquids used in electroplating, or the electrolyte of storage batteries. July 30.

14,971. P. J. R. Dujardin. Secondary batteries. August 6.

15,230. Sir W. Vavasour. Electric batteries. August 20.

17,060. T. Paeker. Electrical furnaces and their manipulation. July 30.

19,080. H. T. Cheswright. Plates for secondary or other voltaic batteries. August 13.

1890.

3731. The Mining and General Electric Lamp Company, Limited, and D. G. FitzGerald. Positive elements of secondary batteries, applicable as cathodes in electrolysis. August 13.

4246. Sir C. S. Forbes, Bart. Primary batteries, and switching apparatus therefor. August 13.

7988. C. L. Coffin. Welding metals electrically. August 6.

7989. C. L. Collin. Welding metals by electricity. August 6.  
 7990. C. L. Collin. Electric welding. August 6.  
 7991. C. L. Collin. Electric welding. August 6.  
 7992. C. L. Collin. Electric welding. August 6.  
 7993. C. L. Collin. Welding metals electrically. August 6.  
 7994. C. L. Collin. Welding metals electrically. August 6.  
 9857. M. W. Dewey. Welding, soldering, brazing, &c., by electricity, and apparatus therefor. July 30.  
 10,181. T. M. Foote. Secondary batteries. August 13.  
 10,515. A. J. Jarnan. Connector for the electrodes and cells of electrical batteries. August 13.

## XII.—FATS, OILS, AND SOAP MANUFACTURE.

### APPLICATIONS.

- 11,360. J. Baptista. Facilitating the use of mineral or other non-saponifiable oils in the manufacture of soaps. July 21.  
 11,629. W. N. Hartley and W. E. B. Blenkinsop. Improvements in decolourising vegetable oils in the manufacture of pale drying oils and varnishes, and apparatus therefor. July 24.  
 11,956. G. Tall. Improvements in refining cotton-seed and other fatty oils. July 31.  
 12,000. F. Walton. A process for oxidising and drying vegetable oils. July 31.  
 12,047. C. Wimpess. An improved washing or laundry powder. August 1.  
 12,373. I. Roos. An improved manufacture of saponifiable fatty matter from wool fat. August 7.  
 12,864. E. J. T. Digby. Improvements in the manufacture of soap. August 16.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

- 14,914. W. G. Little. Improvement in soap. August 6.  
 16,518. T. Anyon. Composition of soap. August 20.

1890.

9614. P. A. Newton.—From The Chesebrough Manufacturing Company. Manufacture of compressed cakes of soap. July 30.

## XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

### APPLICATIONS.

- 10,976. T. H. Davis and A. H. Davis. The purification of coal tar and rendering same a suitable paint or coating or iron or steel structures. July 15.  
 11,359. J. Baptista. Facilitating the use of mineral or other non-oxidising oils in compounding paints and paint oils. July 21.  
 11,602. G. Bischof. A process for manufacture of white lead. July 24.  
 11,629. W. N. Hartley and W. E. B. Blenkinsop. See Class XII.  
 11,640. M. N. d'Andria. Improvements in the manufacture of white lead and nitrate of ammonia. July 25.  
 11,780. J. A. Maynard. A novel manufacture of oil paint in sheets. July 28.

- 12,085. J. J. Lee. The application of certain waste materials for the production of a new or improved "mineral white," and improvements in the process of manufacture. August 1.

- 12,123. G. Macaulay-Cruikshank.—From E. Pietzcker, Germany. Improvements in the preparation of rapidly-drying resinous and other oils or varnishes. August 2.

- 12,230. T. Christy. An improved material for use as a substitute for gutta-percha, rubber, oiled, and other transparent tissues, and for other purposes. August 5.

- 12,414. E. V. Gardner. Improvements in the manufacture of white lead, and in apparatus employed in such manufacture. August 8.

- 12,474. J. C. Martin. Improvements in pigments or paints. August 9.

- 16,684 J. S. Fairfax.—From F. Crane, United States. Improvements in or relating to varnishes or other coatings. August 13.

### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

- 14,569. F. Eckstein. Translucent plastic compositions. July 23.

- 14,797. R. Barton. Paints or compositions. July 23.

- 17,236. G. E. Heyl. Insulating compositions for cables. August 20.

1890.

9822. A. J. Boulton.—From W. Kiel. Manufacture of vulcanised plastic compounds. August 6.

9897. J. Gordon. White lead pigments. August 13.

- 10,130. M. Alsberg. Producing minimum. August 6.

- 20,616. G. R. B. Kempton. Blue for laundry and other purposes. August 13.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

### APPLICATIONS.

- 11,397. J. M. Pujos. Improvements in tanning. July 21.  
 12,751. J. B. Scammell and P. W. Ellis. Improvements in tanning. August 14.

## XV.—AGRICULTURE AND MANURES.

### APPLICATION.

- 11,800. H. Moon. Improvements in the manufacture of artificial manure. July 28.

### COMPLETE SPECIFICATIONS ACCEPTED.

1890.

575. M. C. Ginster. Manufacture of manures or fertilisers. August 13.

9729. H. H. Lake.—From H. Neuminger. Manufacture of acid phosphates for use as manure. July 23.

## XVI.—SUGARS, STARCHES, GUMS, Etc.

## APPLICATIONS.

11,473. J. Duncan. Improvements in the treatment of molasses or syrup for the purpose of improving its flavour. July 22.

11,612. D. Stewart. Improvements in separating saccharine juices, and in centrifugal apparatus therefor, and applicable for other analogous purposes. July 25.

11,683. J. Duncan. The treatment of sugar beet and other roots for the conservation and concentration or drying thereof. July 25.

12,048. C. Wimpess. An improvement in the manufacture of self-glazing starch. August 1.

12,635. H. H. Lake.—From L. Sterberg, United States. Improvements in sugar refining. Complete Specification. August 12.

## COMPLETE SPECIFICATION ACCEPTED.

1889.

13,555. R. Raeymaeckers. Process and apparatus for concentration of saccharine and other liquids, and obtaining crystals thereof. August 6.

## XVII.—BREWING, WINES, SPIRITS, Etc.

## APPLICATIONS.

11,057. A. M. Clark.—From A. Bohringer, Germany. Improved process for extracting tartaric acid from tartar wine lees and kindred substances. July 15.

11,226. E. Craddock. Improvements in apparatus for the treatment of grain for the production of malt. July 18.

11,249. A. Regel. Improvements in pasteurising apparatus. July 18.

11,554. G. F. Redfern.—From J. F. H. Gronwald, E. H. C. Oehlmann, and G. H. Neuhauss. *See Class XVIII. A.*

11,613. T. Reade. A novel preparation for fining or frothing, or imparting a foam to, beer and other fermented beverages. July 24.

11,672. C. O. Gridley and A. Bishop. Improvements in apparatus for the manufacture of finings and other analogous materials. July 25.

12,260. A. W. Ellis. Improvements in distillation and in apparatus therefor. Complete Specification. August 5.

12,834. F. Sauer. A new beverage termed "Malt wine." August 15.

## COMPLETE SPECIFICATIONS ACCEPTED.

1889.

14,928. A. Manbré, sen. Manufacture of refined malt and extract from barley malt, or barley malt and amylaceous substances; and treatment of the spent grains for production of cattle food. July 23.

15,064. A. Manbré, sen. Manufacture of methylated spirit, and treatment of the by-products. July 23.

16,093. W. P. Thompson.—From La Société Générale de Maltose. Process for the saccharification and fermentation of amylaceous matter. August 13.

1890.

4982. M. Hanford. Apparatus for cooling and aerating hot worts. August 20.

## XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

## APPLICATIONS.

*A.—Chemistry of Foods.*

10,950. M. Persson. Improvements in or relating to the preparation of condensed cream. Complete Specification. July 14.

10,961. N. Etienne and A. Delhaye. An improved method of preparing peptonised soluble meat and peptone. July 14.

11,554. G. F. Redfern.—From J. F. H. Gronwald, E. H. C. Oehlmann, and G. H. Neuhauss, Germany. Improvements in apparatus for sterilising milk and other liquids, and for drawing off or decanting the same. Complete Specification. July 23.

11,586. V. Tobias and H. Fischer. A liquid chocolate, free from fat, and preservable. Complete Specification. July 24.

12,298. C. Huelser.—From F. J. Chevet, France. Process for making, and composition of, a conserved product for coffee and milk. August 6.

12,310. S. S. Bromhead.—From F. J. Chevet, France. A preparation of maté and milk. August 6.

12,318. J. G. Lorrain.—From F. J. Chevet, France. A new or improved alimentary product, and process of manufacturing the same. August 6.

*B.—Sanitary Chemistry.*

11,048. T. Douglas. The removing from sewers of the gases generated therein, and for the disinfecting and disposing of them. July 15.

12,290. F. Boshardt.—From J. Roland, France. A process and apparatus for treating refuse. August 6.

*C.—Disinfectants.*

12,323. H. H. Lake.—From W. F. Simes, United States. An improved compound for disinfecting and other purposes. Complete Specification. August 6.

## COMPLETE SPECIFICATIONS ACCEPTED.

*B.—Sanitary Chemistry.*

1889.

14,500. T. Jones and J. Jones. Materials for purifying sewage or polluted water from works, &c. July 30.

*C.—Disinfectants.*

1890.

8838. D. C. Mackenzie. Absorbent, deodorising, and disinfectant preparation. August 6.

## XIX.—PAPER, PASTEBOARD, Etc.

## APPLICATIONS.

10,992. A. Morton and F. L. Leech. Improvements in the method of and means for waterproofing paper. July 15.

11,021. J. B. Atherton.—From L. D. Beck, United States. Improvements in the manufacture of Manila paper. July 15.

11,420. J. Lewis. Improvements in paper used for photographic printing. July 22.

11,754. W. Thomson and J. Richards. Improvements in the manufacture of waterproof cardboard, and waterproof cardboard boxes or other receptacles. July 28.

12,139. W. Rogers. Improvements in the preparation or treatment of paper for copying letters, documents, and the like, including such as are done with a type-writing machine, and improvements in chemical compounds, or preparations therefor. Complete Specification. August 2.

12,375. W. Marshall Campbell-Caldender. The manufacture of a new material designed to serve as a substitute for bone or celluloid. Complete Specification. August 7.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1890.

4959. C. Kellner. Boilers for manufacture of sulphite cellulose, and method of heating same. August 6.

5128. C. Kellner. Modifying the properties of fibres used in the manufacture of paper. July 23.

5500. E. G. Wrigley. Manufacture of absorbent sheets, rolls, or pads of paper. August 20.

6158. P. Whiteside. Absorbent writing paper. July 30.

8353. J. Hawke. Manufacture of copying paper. August 6.

#### XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

##### APPLICATIONS.

11,189. W. R. Lake.—From Kalle and Co., Germany. Improvements relating to the preparation of hydrochlorides, hydrobromides, and hydriodides of peptone. July 17.

11,196. G. D. Bowie. Phosphated salt: sal. phosph. July 18.

12,729. H. Cumber. A compound of sugar with the salts of phosphorus for dietetic purposes. August 14.

#### XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

##### APPLICATIONS.

11,104. E. Edwards.—From O. Moh, Germany. An improved method of preparing photographic plates of mica. Complete Specification. July 16.

11,420. J. Lewis. See Class XIX.

11,945. B. J. Edwards. Improvements relating to the manufacture of flexible films for photographic and other purposes, and to apparatus for use in such manufacture. July 30.

11,986. F. T. Knott. An improvement in the application of photography to textile fabrics. July 31.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1889.

11,701. J. Molloch. A glass plate or other transparent substance coated with a non actinic film, and used as a negative for photographic and other purposes. July 23.

1890.

11,104. E. Edwards.—From O. Moh, Germany. An improved method of preparing photographic plates of mica. August 20.

#### XXII.—EXPLOSIVES, MATCHES, Etc.

##### APPLICATIONS.

10,935. A. Hislop.—From J. Storer, Australia. Improvements in the making of wax vestas. July 14.

11,018. W. P. Thompson.—From S. D. Smolianoff, United States. Improvements in explosive compounds. Complete Specification. July 15.

11,202. G. Bruck. Improvements in the manufacture of headless matches. July 18.

11,720. R. J. Jones and G. Worrall, on behalf of Woodhouse and Rawson, United, Limited. Improvements in connexion with electrical fuses. July 26.

11,745. H. J. Haddan.—From J. H. Voelkel, Germany. Improved vacuum drying apparatus for explosive substances. Complete Specification. July 26.

12,094. R. Morris. An electric fuse for firing guns. August 1.

12,785. A. L. Brociner. The manufacture of a new explosive. August 15.

#### COMPLETE SPECIFICATION ACCEPTED.

1890.

8481. P. Ward and E. M. Gregory. Priming and detonating composition. July 23.

OF THE

# Society of Chemical Industry:

## A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 9.—Vol. IX.]

SEPTEMBER 30, 1890.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.]

## The Society of Chemical Industry.

### Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S. ....	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S. ....	1882—1883.
Walter Weldon, F.R.S. ....	1883—1884.
W. H. Perkin, Ph.D., F.R.S. ....	1884—1885.
E. K. Muspratt ....	1885—1886.
David Howard ....	1886—1887.
Prof. James Dewar, F.R.S. ....	1887—1888.
Ludwig Mond ....	1888—1889.
Sir Lowthian Bell, Bart., F.R.S. ....	1889—1890.

## COUNCIL FOR YEAR ENDING JULY, 1891.

*President:* E. Rider Cook.

### Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond.
R. Forbes Carpenter.	Dr. Hugo Muller, F.R.S.
Prof. James Dewar, F.R.S.	B. E. R. Newlands.
James Duncan.	Dr. W. H. Perkin, F.R.S.
David Howard.	Dr. Edw. Schneck, F.R.S.
S. H. Johnson.	J. C. Stevenson, M.P.

### Ordinary Members of Council:

A. H. Allen.	Prof. R. Meldola, F.R.S.
L. Archbutt.	E. K. Muspratt.
S. B. Boulton.	T. L. Patterson.
Jno. Brock.	Jno. Pattinson.
Jno. Calderwood.	Jno. Spiller.
H. Grimshaw.	T. W. Stuart.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

### Honorary Foreign Secretary:

Dr. Ferdinand Hurter.

*General Secretary:* Charles G. Cresswell.

### Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

## THE JOURNAL.

### Publication Committee:

The President.

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	Ivan Levinstein.
Joseph Bernays, M.I.C.E.	Prof. R. Meldola, F.R.S.
H. Brønner.	Ludwig Mond.
W. Lant Carpenter.	E. K. Muspratt.
Prof. Frank Clowes, D.Sc.	B. E. R. Newlands.
W. Y. Dent.	C. O'Sullivan, F.R.S.
Prof. Jas. Dewar, F.R.S.	John Pattinson.
John Heron.	W. H. Perkin, Ph.D., F.R.S.
D. B. Hewitt, M.D.	Sir H. E. Roscoe, M.P., F.R.S.
David Howard.	John Spiller.
Prof. J. J. Hummel.	A. Norman Tate.
	Thomas Tyrer.

### Editor:

Watson Smith, University College, London, W.C.

## NOTICES.

Foreign and Colonial Members are hereby advised that the subscription of 25s. for 1891, payable on January 1st next, should be sent in good time to the Treasurer in order to ensure continuity in the receipt of the Society's Journal. Any changes of address which it is desired should appear in the new List of Members should reach the General Secretary not later than January 15th, 1891.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

### CHANGES OF ADDRESS.

Alexander, J. O., 1/o Plymouth; 11, Avenue Road, South Norwood Park, Surrey.

Allen, G. J., 1/o 27; Ivy House, Bolton Road, Pendleton, Manchester.

Aubrey, W. H., 1/o Lewisham; St. Mawes, Cornwall.

Bowman, R., 1/o Middlesbro'; Elabouga, Government of Viatka, Russia.

Bramwell, S., 1/o St. Ann's Square; 18, St. Ann's Street, Manchester.

Brasher, F. W., 1/o Plymouth; 4, Wyatt Road, Forest Gate, E.

Bürger, Dr. J., 1/o Crumpsall; 1, Birch Avenue, Talbot Road, Old Trafford, Manchester.

Ekman, C. D., 1/o Dieppe; Santa Maria, Serra San Bruno, Calabria, Italy.

Fletcher, Thos., 1/o Warrington; Grappenhall House, Grappenhall, near Warrington.

Gillman, G., 1/o Almería; Ferro-carril de Murcia á Granada, Lorca, Prov. de Murcia, Spain.

Grant, A. L., 1/o Gould Street; 20, Bay Street, Toronto, Canada.

Holdich, A. H., 1/o Wigan Coal and Iron Co.; 4, Rowbottom Square, Wigan.

McDonald, P. C., 1/o Sydney; Stanley Villa, Stanmore, New South Wales.

McKean, Wm., 1/o Victoria Mansions; 14, Palmer Street, Westminster, S.W.

McRoberts, G., 1/o Ardrossan; Todhill, Newton-Mearns, Renfrewshire, N.B.

Moore, Dr. Gideon E., 1/o Liberty Street; 221, Pearl Street, New York, U.S.A.

Morgan, A. F., 1/o Manchester; Lindum House, Seunthorpe, via Doncaster.

O'Beirne, W. G., 1/o Clydebank; Sheppy Glue and Chemical Works, Queenborough, Kent.

Petty, A., 1/o Shooter's Hill; 23, Linthorpe Road, Stamford Hill, N.

Redwood, Dr. T., 1/o London; Boverton, near Corbridge, Glamorganshire.

Reel, Albert E., 1/o Sidenup; Devonshire House, Pelham Road, Gravesend.

Schroeter, H. J. M., 1/o Philadelphia; 615, West Van Buren Street, Chicago, Illinois, U.S.A.

Singer, Ign., 1/o Calverley; 13, Holker Street, Keighley, Yorks.

Smith, A. J., 1/o Greenheys; 55, Ackers Street, Chorlton-on-Medlock, Manchester.

Sutherland, D. A., 1/o Whitehaven; 2, Victoria Mansions, Westminster, S.W.

Thomson, G. C., 1/o Dunfermline; 86, St. Vincent Street, Glasgow.

Voss, H., 1/o South Norwood; Holstein House, Penge Road, Beckenham, Kent.

Wills, J. Lanson, 1/o Buckingham; 206, Albert Street, Ottawa, Canada.

Feb. 2nd.—Dr. W. S. Squire. "The Artificial Production of Cold Theoretically and Practically considered."

## Communication.

### CONTRIBUTIONS TO THE ANALYSIS OF FATS.

BY J. LEWKOWITSCH, PH.D., F.I.C., F.C.S.

(Read before Section B., British Association, Leeds.)

On an occasion like this it may perhaps not be out of place for me, before entering on the original part of my paper, to give in short outlines a review of the analytical methods which are at present being employed in the analysis of fats. And here one cannot help being struck with the fact that, while the manufactures dealing with fats and oils have been enormously developed, and are playing a most important part in the list of chemical industries, the analytical research into the ultimate composition of them has been sadly neglected. From the ever-memorable researches of Chevreul, which created the scientific basis for these industries, up to a few decades the analytical material at the command of the chemist has been a very scanty one. The examination of physical properties and some chemical methods, perhaps more of a rule of thumb than of a scientific character, have been nearly the only guides for the analyst. The growing adulteration, almost developed to a fine art, especially that of butter, has created a necessity for inventing new methods; and, thanks to this pressure, methods have been found which, though very far yet from allowing an insight into the bewildering and almost inextricable mixtures of fatty acids occurring in nature, have given valuable material into the hands of the chemist, upon which we may hope to build up a complete analytical examination of fats.

The fats and oils are, as well known, the glycerides of fatty acids belonging to the series—

In nature occur exclusively the triglycerides. There has been found by Will and Reimer in old rape oil the diglyceride of erucic acid,  $C_{21}H_{41}(OH)(OC_{22}H_{41}O)_2$ , but this exception is only an apparent one, as it is most likely that the rape oil had undergone that change which is generally known as turning rancid, so that free erucic acid had been formed, while dierucic acid separated as a solid mass. In some cases this process of decomposition may have been progressing further, and the fats may contain a larger amount of free fatty acids, until they may reach as high a percentage as 80—90 per cent., which is known to occur in the case of old palm oil. However, we must still assume that in nature only the triglycerides are found, as proved by the examination of freshly prepared fats.

The analytical examination of fats will naturally bear on the examination of the constituents into which they are resolved on undergoing hydrolysis or saponification, namely, into glycerol and fatty acids. The first operation will therefore be to carry out this splitting up into the components; the fatty acids, being mostly insoluble in water will be separated, while the glycerol will remain in aqueous solution.

The exact determination of the glycerol in fats has been, up to a very short time ago, a difficult operation, so much so that it could only be determined approximately; it was extracted by means of a mixture of ether and alcohol, after the neutralised aqueous solution had been boiled down nearly to dryness, from the residual salts. But on evaporating the solution on the water-bath, the glycerol soon reached a concentration when it began to volatilise, which rendered, of course, the result inaccurate. Although this source of error might have been obviated by the somewhat tedious method to free the glycerin from the last traces of ether and alcohol and water by allowing it to stand in a desiccator until the weight remained constant, still, this method necessarily gave inaccurate results, as the glycerin had finally to be incinerated in order to deduct the amount of ashes. But along with the glycerol other organic substances, which would naturally be contained in such a

crudely prepared glycerin, would be burnt at the same time and therefore the result would be found too high.

The elegant method of Benedikt and Zsigmondy, which is based on the oxidation of glycerol to oxalic acid by means of potash permanganate will, for this very reason, although permitting a higher grade of accuracy, leave some uncertainty as some organic impurities might also yield oxalic acid.

The indirect method of determining the glycerol by the amount of potash required in saponifying the *neutral fat*, i.e., the triglycerides, according to the equation—

has all the faults of an indirect method and therefore it need not be discussed here.

I proposed therefore to use Benedikt's and Cantor's acetin method, which as I have shown before gives very concordant and accurate results. The method is based on a process expressed by the following equation—

On hydrolysing the triacetin the quantity of alkali required for it and consequently the glycerol may be easily determined. When the fats have been saponified the glycerin may be extracted, as indicated above, with a mixture of ether alcohol, and the latter evaporated and the substance finally dried in the desiccator. It is not necessary to wait until the weight becomes constant, as a percentage of water up to 10 per cent. does not interfere with the acetin process; furthermore, a determination of ashes becomes superfluous. The results I obtained in this way are very satisfactory indeed, and I think this method would recommend itself to the analyst for the estimation of glycerol in wine and beer, where impure crude glycerins are also obtained.

The examination of the fatty acids will in the first instance be directed to the determination of their total amount. If all the fatty acids were insoluble in water it would be easy enough. But as the lower members of the fatty acid series are more or less soluble in water the problem becomes a more complicated one and we are no longer able to apply such exact methods as the mineral analysis gives us at hand. For we must consider that we may have to deal with a mixture of acids of various molecular weights. Therefore recourse has to be taken to the so-called quantitative reactions.

It will perhaps be useful to arrange these reactions under a tabular form in a similar way as it is being done in qualitative analysis of mineral substances (see following table). *a* and *b* are separated by boiling the fatty acids with

#### FATTY ACIDS.

<i>a. Soluble Acids.</i>		<i>b. Insoluble Acids.</i>	
	<i>α-Saturated.</i>		<i>β-Unsaturated.</i>
1.	$C_{17}H_{34}O_2$ yields on oxidation	.....	Dihydroxystearic acid.
2.	$C_{19}H_{38}O_2$ " " .....		Tetrahydroxystearic acid.
3.	$C_{21}H_{42}O_2$ " " .....		Hexahydroxystearic acid.
4.	$C_{17}H_{34}O_3$ " " .....		Trihydroxystearic acid.

water and washing them out repeatedly with boiling water. The insoluble fatty acids are collected on a filter and weighed. The percentage of insoluble acids—the so-called Hehner's value—is a very valuable criterion for the nature of some fats. In the case of fats resembling tallow, Hehner's value will be about 95 per cent., whilst, e.g., for butter the upper limit is 88 per cent. This method enabled chemists to test the butter for the presence of oleomargarine, until the adulterator has found in the cocoa-nut oil a ready means to gauge his adulteration in such a way as to accommodate his mixture to Hehner's test.

It became therefore necessary to examine the soluble fatty acids, and this is done by determining the so-called Reichert's value. This latter is found by saponifying a fat

with caustic alkali, decomposing the soap by means of sulphuric acid and distilling the mixture, when the volatile, water-soluble acids pass over, and may be estimated by titration with caustic potash. This method has been specially devised for the examination of butter fat and represents at present the best means of stating the genuineness of butter. But it is to be feared that the inventiveness of the adulterator will even mar this test by finding fats which, when added to an artificial butter, will produce a Reichert's value approaching that of a genuine butter. Such fats would be, for instance, the glycerides of valeric acid as they are found in porpoise oil.

If we express the amount of fatty acids, both soluble and insoluble, by the number of milligrammes of caustic potash

required for their neutralisation, we shall, on adding these values, find, of course, the number of milligrammes of caustic potash necessary to saturate all the fatty acids contained in a fat. It is evident that this value may be determined at once at the outset, and this constitutes the valuable method devised by Kottstorfer and known to give the so-called Kottstorfer's value, *i.e.*, the number of milligrammes of caustic potash required for the fatty acids of one gramme of fat. This value has also been called the saponification value, not quite correctly perhaps, if by saponification be understood the process of hydrolysing fats and transforming the fatty acids thereof into soap. Most fats contain, for some time after they have been rendered free, fatty acids, and these are at the same time transformed into soaps along with the fats hydrolysed. The Kottstorfer value in most cases comprises therefore the sum of two distinct values, namely, that for neutralising the free fatty acids, and that for saponifying the neutral fats; this latter value has appropriately been called the ether value.

The determination of the free acid in a fat will, therefore, constitute the next step, and is easily carried out by titrating the fat with potash in alcoholic solution, using phenolphthaleïn as an indicator. We shall not find the actual amount of free fatty acids, as we do not know their molecular weight, but we shall have again a value, always expressed in milligrammes of potash, which allows us to approximately calculate the amount of free fatty acids, if we make the assumption that the free fatty acids have the same mean molecular weight as the bulk of fatty acids contained in the fat.

To find the mean molecular weight, we shall best examine the insoluble fatty acids *b*. As they represent, as a rule, a mixture of different acids, we can only determine their mean molecular weight. We find this simply by titrating with caustic potash, and expressing the result in milligrammes of caustic potash per gramme of fatty acid. This value *A*, the so-called acid value, allows us to calculate the molecular weight according to the following proportion:—

$$M : 56 \cdot 1 = 1 : A ; M = \frac{56 \cdot 1}{A}$$

If molecular weights are found, which lay near either end of the following table:—

Acid.	Formula.	Mol. W.
Myristic acid .....	$C_{14}H_{28}O_2$	228
Palmitic acid .....	$C_{16}H_{32}O_2$	256
Linolenic acid .....	$C_{18}H_{34}O_2$	278
Linoleic acid .....	$C_{18}H_{32}O_2$	280
Oleic acid .....	$C_{18}H_{34}O_2$	282
Stearic acid .....	$C_{18}H_{36}O_2$	284
Ricinolic acid .....	$C_{18}H_{34}O_3$	298
Erucic acid .....	$C_{22}H_{42}O_2$	338

it will be seen at once in which direction further research into the nature of the acids will have to be carried on. But most of the fats contain fatty acids whose molecular weights range from 256 to 284, and small quantities of ricinolic, &c. acids may easily escape being noticed, if conclusions were to be drawn from the mean molecular weight only.

The fatty acids given in the last table belong to different series, which we may at once divide into two classes, saturated and unsaturated acids, *a* and *b*. The presence of unsaturated fatty acids will best be detected by applying Hübl's reaction—that is, by determining the so-called iodine absorption values. This test adds another valuable method to those enumerated above, and gives, in a great many instances, most indispensable hints as to adulterations, for instance, of tallow with cotton-seed oil.

If the unsaturated fatty acids present besides the saturated acids consisted of oleic acid only, it would be easy

to calculate from the amount of iodine absorbed the exact quantity of oleic acid according to the following equation—

For every gramme of iodine absorbed there must be present  $\frac{284}{254} = 1 \cdot 1102$  grms. oleic acid. But as a rule we must be prepared to pre-suppose the presence of other acids belonging to the other series of unsaturated acids, and their separation from the saturated acids and from one another becomes therefore necessary.

The solubility of the lead salts of the unsaturated fatty acids in ether, which does not dissolve the lead salts of the saturated fatty acids, admits in the first instance of the separation of the unsaturated fatty acids from those belonging to the series  $C_{18}H_{34}O_2$ . It has hitherto been supposed that this solvent allows the complete separation of the acids *a* and *b*, but, as I shall show later on, this may be doubted. However, for practical purposes, we may assume here that the separation is a complete one. The acids *a* will have to be resolved by fractional crystallisation of their lead—or barium—or magnesium salts into their single constituents. The determination of their mean molecular weight will serve as a convenient guide. If a value *M* be found lying between 256 and 284—the mol. weights for palmitic and stearic acids—and there is reason to assume that these two acids only are present, their actual amount *x* and *y* may be determined from the following two equations—

$$x + y = 100.$$

$$2 \cdot 56 x + 2 \cdot 84 y = M.$$

If therefore the fatty acids *b* contain exclusively oleic, palmitic, and stearic acids, it would be quite possible to determine their absolute amounts. Of course, the iodine absorption value does not indicate at all the nature of the unsaturated fatty acids, which may belong to one or more of the four different series represented in the table sub-numbers 1–4 by four acids actually found in some fats. An elegant method to at least qualitatively prove the presence of these acids has been given by Hazura. His method is based on the fact that the unsaturated acids, like perhaps all unsaturated derivatives of the fatty series, are oxidised in alkaline solution, by means of potash permanganate in such a way that each  $CH = CH$  group is transformed into a  $CH(OH) - (OH)CH$  group. Thus oleic acid would yield on oxidation dihydroxystearic acid, &c., as indicated in the table. The resulting acids are well characterised, and may be separated in a convenient way, as has been shown by Hazura.

At the hand of a practical example the usefulness of the above-mentioned methods may be clearly demonstrated. I examined the fat extracted from the Sawarri nuts, and found the following figures:—

Hegner's value .....	96.9 per cent. (insoluble acids)
Reichert's value .....	0.65 per cent. (soluble acids)
Kottstorfer's value .....	199.51
Mean molecular weight of the insoluble acids .....	272.82
Free acids (Mol. W. 272.8) .....	2.4 per cent.
Glycerol .....	9.1 "
Iodine value of the fatty acids .....	51.5

The low Reichert's value and the high Hegner's value show that the amount of volatile soluble acids may be neglected. The mean molecular weight, 272.82, seems to point to the presence of oleic, palmitic, and stearic acids only. In order to resolve the insoluble fatty acids into their components, they were transformed into their lead salts by double decomposition of the neutral sodium salts with lead acetate, and repeatedly extracted with ether. It was, however, found that the ether did not dissolve the lead salts of the unsaturated acids completely, for the insoluble lead salts yielded, even after a great many extractions, on being decomposed with sulphuric acid, fatty acids which showed by their capacity of absorbing iodine that they

still contained a certain amount of unsaturated fatty acids. As further extraction seemed to prove of no use, inasmuch as the iodine value of the fatty acids constituting the insoluble lead salts remained constant at 5.8, I had to renounce the hope of bringing the separation to an end in this way. It was thought possible to concentrate, so to speak, by fractional crystallisation of the acids yielding the insoluble lead salts, the unsaturated acid into one fraction, and therefore the insoluble lead salts were decomposed by means of sulphuric acid, and repeatedly boiled with water slightly acidulated with this acid in order to remove the last traces of lead salts, which, by being enveloped in the free fatty acid, easily escaped decomposition.

The free acids were dissolved in absolute alcohol, and yielded seven consecutive crystallisations; the filtrate from the last crystallisation was freed from alcohol by heating on the water-bath, thereby giving an eighth and last quantity of acids. The melting points of these eight fractions were as follows:—

Fraction.	Melting Point.	Solidifying Point.
	°C.	°
1st	60.0–61.0	58.3
2nd	61.2–65.5	60.0
3rd	61.0–61.5	60.0
4th	61.0–63.0	60.0
5th	61.0–62.0	58.3
6th	56.5–59.5	54.5
7th	57.5–60.0	55.5
8th	46.5–50.0	44.4

The iodine absorption values of the first, fourth, and eighth fraction were 1.66, 1.65, and 25.05.

The first two values lie within the experimental errors of the method, and may therefore be neglected; the last value, however, demonstrates clearly that the unsaturated acid accumulated in the last fraction. The determination of the mean molecular weight of the three fractions (first, fourth, and eighth) showed for the—

1st fraction .....	258.4
4th „ .....	262.0
8th „ .....	309.0

pointing to the explanation that the first fraction is nearly pure palmitic acid, which in the higher fractions is being partly replaced by stearic acid. A further study of these acids by means of fractional crystallisation of their lead or magnesium salts will give a final answer as to their ultimate composition.

The soluble lead salts were decomposed in the same way, the liquid acids repeatedly washed and freed from the last traces of water. After having been kept for some time in a desiccator the liquid acids became of a butter-like consistency; from which, however, it was not possible to separate the solid constituent. The mean molecular weight of the acids was found at 297.5, the iodine value 68.85, thus proving, in addition to the physical properties of the acid, that the liquid acids contained besides the supposed oleic acid (molecular weight 282, iodine value 90), one or more other acids. The oxidation of the acids by means of potash permanganate according to Hazura was expected to give a better insight into the composition of these fatty acids. As the iodine value has been found so low it was hardly likely that acids of the series  $C_nH_{2n-4}O_2$  and  $C_nH_{2n-6}O_2$  would be present. The detection of any hydroxylated fatty acids will be mentioned later on.

30 grms. of the unsaturated acids—as I will call them—were dissolved in 36 cc. caustic potash of 1.27 sp. gr. and the soap dissolved in 2 litres of distilled water. To this solution was gradually added a 1½ per cent. solution of potash permanganate until the liquor remained pink for some time; 2,500 cc. of the permanganate solution was added. I hasten

to explain that this *modus operandi* is against Hazura's prescriptions, whose papers I knew at that time from abstracts only. Hazura prescribes in his later publications that 30 grms. of the acids, neutralised as above, should be mixed with 2 litres of a 1½ per cent. solution of potash permanganate, and that after standing for 10 minutes the surplus of permanganate should be reduced by means of sulphurous acid. Therefore it will be easily explained why I found considerably quantities—over 5 grms.—of dibasic water-soluble acids.

The slight excess of potash permanganate was removed by means of sulphurous acid, and the potash salts decomposed by sulphuric acid, when a precipitate of insoluble acids was obtained. These were collected and dried under a desiccator; their weight was 28 grms.

By means of purified ether these acids were extracted four times, 2 litres being used each time. Thus, four extracts were obtained, while the insoluble acids remained behind. The first extract amounted to about 18 grms., the substance was jelly-like, dissolved readily in alcohol, but did not crystallise from it. As the substance did not absorb iodine, it was first considered to be a saturated fatty acid, the lead salt of which had been dissolved by ether. But on further examination it was found that it was no acid, for when shaken up with water and titrated with decinormal potash after adding a little phenolphthalein, it was not neutralised at once, the pink colour only gradually disappearing after some time. Alcoholic potash, however, saponified the substance readily, giving a saponification value of 271.2. The fatty acid obtained from the soap gave an acid value of 182.5, corresponding to a molecular weight of 305. These figures, on account of the small quantities with which I had to carry out my experiments, do not admit of certain conclusions, and this much seems only proven that the substance is an inner anhydride of a hydroxylated fatty acid of the general formula—

pointing to the existence of an acid of the formula—

The second, third and fourth extracts were nothing else than small quantities of the bulk of the acids which are not altogether insoluble in ether, and were later on added to them.

The bulk of the acids was repeatedly boiled out with water without, however, losing in weight, whereby the absence of linolic and isolinolic acids was proved. The acids could therefore, providing the original acids contained 18 atoms of carbon, only consist of dihydroxystearic, trihydroxystearic, and sativic acids. On repeatedly recrystallising them from absolute alcohol it was, however, found that only one acid was present, all fractions yielding acids of a melting point lying between 125° and 130°. The last filtrate was evaporated to dryness and gave as residue a dark-coloured acid melting between 117° and 119°. The absence of sativic acid,  $C_{18}H_{32}(OH)_2O_2$ , melting point 173°, and also of isotrihydroxystearic acid,  $C_{18}H_{34}(OH)_3O_2$ , melting point 110°–111°, was therefore proved. The oxidised acid could only be dihydroxystearic acid,  $C_{18}H_{34}(OH)_2O_2$ , melting point 137°, mixed perhaps with small quantities of trihydroxystearic acid, melting point 140°–142°. The determination of the molecular weight and an elementary analysis could easily decide this question. The acid was therefore recrystallised from absolute alcohol, and the crystals showing every sign of purity, melting point 132°–133°, analysed.

0.4059 grm. gave 0.4224 grm.  $H_2O$  and 1.008 grm.  $CO_2$ , wherefrom—

Experiment.	Theory for $C_{18}H_{34}(OH)_2O_2$ .	Theory for $C_{18}H_{32}(OH)_2O_2$ .
C	67.70	68.3
H	11.56	11.8
		65.06
		10.84

The molecular weight, determined by titration with half normal caustic potash, was found, for a monobasic acid, to be 316·19; theory requires for dihydroxystearic acid, 316. The acid may therefore be considered as pure dihydroxystearic acid formed from oleic acid.

The water-soluble acids were obtained by neutralising the sulphuric acid after the dihydroxystearic acid had been filtered off and boiling the liquor down until potassium sulphate began to separate. The solution was now acidulated and the dibasic acid extracted with ether. After repeated crystallisation from water (charcoal having been used to remove colouring substances) an acid was obtained of the melting point of 126°–130°.

On titrating with caustic potash, an acid value of 622 was found corresponding, for the unavoidable assumption that a dibasic acid was present, to the molecular weight 180·2. Azelaic acid, melting point 106°, has the molecular weight 188; suberic acid, melting point 140, has the molecular weight 174; it is therefore not to be doubted that I had in my hands a mixture of azelaic and suberic acids.

I hope to get a fresh supply of the somewhat rare Sawarri nuts in order to repeat the oxidation and determine the nature of the supposed hydroxylated fatty acid.

For the detection and determination of hydroxylated fatty acids (No. 4 of our table) Benedikt had proposed a method based on the principle that hydroxylated fatty acids, on being heated with acetic anhydride, exchange the hydrogen of their hydroxyl group or groups with the radicle of acetic acid, whilst those acids which do not contain any hydroxyl group remain unaltered when subjected to the same operation. On neutralising and saponifying such hydroxylated acids Benedikt found two values, expressed in milligrammes of caustic potash, the difference of which yielded his "acetyl value." As an illustration he gave the following two equations, *e.g.*, for ricinolic acid—

I.

II.

I have, however, recently shown (Proc. Chem. Soc. 1890, 72, 91; this Journal, 1890, 660), that Benedikt's method may lead to erroneous results, as all fatty acids on being boiled with acetic anhydride yielded the anhydrides of the fatty acids, and I proved that Benedikt's "acid values" obtained according to the first equation had no quantitative meaning at all.

In my first note in the Proceedings I had only shown that working after Benedikt one may even get acetyl values for oleic, palmitic, and stearic acids, which, of course, ought to be an impossibility.

As I gave no explanation in my first note, it called forth a reply from Benedikt,\* who, without waiting for my second note, simply declared my results to be wrong. The importance of the method requires further explanation and proof on my part. Before giving these I shall have to refute Benedikt's alleged explanations for my supposed errors. Benedikt assumes two causes of error: firstly, that the acetic anhydride I used has not been pure; secondly, that I did not wash the fatty acids free from acetic anhydride before titration.

As to the purity of the acetic anhydride I used I may state that it had the following boiling point:—

	Degrees.	Per Cent.
Beginning of boiling at .....	134	
Distilled from .....	134–135	3
" .....	136	7
" .....	136·5	16
" .....	137	28
" .....	137·5	46
" .....	138	60
" .....	138·5	79
" .....	139	90

\* Chem. Zeit. 1890, No. 51.

The remaining 10 per cent. were only slightly coloured.

On hydrolysing the acetic anhydride by means of caustic potash, I found the following saponification values:—

1. 7·303 grms. were placed with a large quantity of water into a beaker and titrated with half normal caustic potash; used 285·95 cc., corresponding to a saponification value of 1080; theory requires 1100.

2. 2·5520 grms. were titrated in the same way; used 98·2 cc. half normal potash. Saponification value found, 1087.

3. 1·1516 grms. were saponified by means of half-normal alcoholic potash; used 43·75 cc. Saponification value found, 1066.

These analytical results entirely do away with Benedikt's first objection.

As to the second assumption of Benedikt that I did not wash the resulting fatty acids until free from acetic anhydride, I have to say that I did not explicitly state that this had to be done; for such, indeed, would have been the very first objection I should have raised to myself in order to explain the unexpected results. As a matter of fact, the substances had been washed repeatedly with boiling water, and the precaution was even used not to test for any acid with litmus paper, but with a very sensitive litmus solution. A complete refutation will moreover be found in the figures given in my second note.

But even granting for a moment the absurd supposition that the oleic, palmitic, and stearic acids I mentioned in my first note had not been washed free from acetic anhydride, it is easy to show that the values given by me cannot be explained in this way by Benedikt. From the saponification values I found and from the theoretical saponification values of acetic anhydride, of oleic, palmitic, and stearic acids\* it can be calculated according to the three following equations, how large the percentage of any admixed acetic anhydride might have been.

$$\text{For oleic acid.} \dots 1,100 \frac{x}{100} + 198 \cdot 9 \frac{100-x}{100} = 242, x = 4 \cdot 78 \text{ per cent.}$$

$$\text{For palmitic acid.} \dots 1,100 \frac{y}{100} + 219 \cdot 1 \frac{100-y}{100} = 226 \cdot 13, y = 0 \cdot 79 \text{ per cent.}$$

$$\text{For stearic acid.} \dots 1,100 \frac{z}{100} + 197 \cdot 5 \frac{100-z}{100} = 221 \cdot 18, z = 2 \cdot 62 \text{ per cent.}$$

Assuming, further, that these quantities of acetic anhydride have been left in the "acetylated" products, which were, according to Benedikt, nothing else but the free oleic, palmitic, and stearic acids, and making in addition the (absurd) assumption that any such acetic anhydride has not been hydrolysed, while the "acid value" was being determined in alcoholic solution, we may calculate what ought to have been the "acid values" of such mixtures of oleic, palmitic, and stearic acids with acetic anhydride. We should find—

$$\text{For oleic acid } (100 - 4 \cdot 78) \times 198 \cdot 9 = 189 \cdot 39.$$

$$\text{For palmitic acid } (100 - 0 \cdot 79) \times 219 \cdot 1 = 217 \cdot 37.$$

$$\text{For stearic acid } (100 - 2 \cdot 62) \times 197 \cdot 5 = 192 \cdot 32.$$

While the corresponding figures actually found by me were given as 116·5; 143·3; 138·39.

To remove every doubt I boiled 10 grms. of the oleic anhydride, which had been analysed, four more times with water, 30 minutes each time. 1·1472 grms. of this oleic anhydride shaken up with 25 cc. water, took 0·3 cc. one-tenth normal potash, when it became pink. The wash-waters were slightly acid and required (1) 12·8 cc.; (2) 4·0 cc.; (3) 2·36 cc.; (4) 1·12 cc. decinormal potash; but the wash-water from 10 grms. of the oleic acid, from which I had started, took, treated twice in the same way, 2·9 cc. and 0·8 cc. decinormal potash. I will make another concession, although an inadmissible one, namely, that the acid found in the wash-waters was hydrolysed acetic anhydride which had been retained in the oleic anhydride. I used altogether 12·8 + 4 + 2·36 + 1·12 cc. = 20·28 cc. decinormal caustic potash equal to 0·1138 gm. KOH which

\* For the acids the saponification values are of course identical with their acid values, 198·9, 219·1, 197·5.

corresponds to 0.1217 grm. acetic acid or 0.1034 grm. acetic anhydride, or in other words the oleic anhydride *might* have retained 1.034 per cent. acetic anhydride. Previously I had granted for an equally inadmissible concession 4.78 per cent. anhydride.

The crucial experiment with a mixture of oleic anhydride and acetic anhydride was to give a final answer. To 1.8225 grm. oleic anhydride were added 0.1342 grm. acetic anhydride and this mixture of 93.15 per cent. oleic anhydride and 6.85 per cent. acetic anhydride was shaken up with 25 cc. water, and titrated with one-tenth normal potash. When 27.3 cc. had been added the pink colour appeared, while a perfect emulsion had been formed. The colour disappeared very soon and it took 4.8 cc. more to restore the pink tint; this disappeared very soon again and the mixture took another 1.2 cc. decinormal potash, when the pink colour stayed for about 20 minutes. The above 0.1342 grm. acetic anhydride would require theoretically for complete hydrolysis 38 cc. one-tenth normal KOH, while 33.3 cc. had been used; after 20 minutes 1.3 cc.; after two hours, 6.6 cc.; and after another hour, 5.2 cc. more were required to show an alkaline reaction.

Benedikt adduces as a proof for the correctness of his explanation and observation all the determinations of "acetyl values" that have been carried out by himself and by Hazura in the latter's researches on hydroxylated fatty acids. Hazura had found in all cases "acid values" for the "acetylated" fatty acids, which approximatively agreed with those required by theory. According to my views these "acid values" have only been found because the "acetylated" substances, which were the anhydrides of the acetylated substances, were partly hydrolysed on being titrated in *alcoholic* solution by means of half-normal potash, and this hydrolysis ceased when an equilibrium was established; therefore these figures prove nothing whatever.

In order to give further experimental proof I prepared dihydroxystearic acid from pure oleic acid by oxidising it by means of potash permanganate in alkaline solution. The dihydroxystearic acid was repeatedly recrystallised from alcohol; melting point, determination of the molecular weight, and elementary analysis proved the purity of the substance. 30 grms. of this acid were boiled with 25 grms. acetic anhydride, the mixture was poured into boiling water, and the separated oily layer repeatedly boiled and washed with water until a few cc. of the wash-water had no action on a sensitive litmus solution. The oil was then freed from the last traces of water and filtered in a drying oven. This substance was to be, according to my views, diacetyl-hydroxystearic anhydride, containing perhaps a small quantity of the corresponding acid, which might have been formed by slight hydrolysis of the anhydride.

1.5813 grms. of the substance required for complete saponification, 22.10 cc. of an alcoholic half-normal potash solution corresponding to a saponification value of 392. As the formula—

requires theoretically 430, while the free acid—

requires 420, this result cannot give any decision as to the question at issue, besides showing that either of these two substances had been formed. The substance was oily, viscous, and did not crystallise, so that a purification had not been attempted. But the following two experiments give a decisive answer:—

I.—1.3272 grms. were shaken up with 25 cc. water and after adding phenolphthalein titrated with decinormal potash. When 0.2 cc. had been added, the mixture became pink; this colour disappeared after one minute, and after the following times, 2, 2, 1, 3, 6, 9, 16, 60 minutes, the following quantities of decinormal potash added were used up 0.4 cc.; 1.1 cc.; 1.1 cc.; 1.1; 1.0; 1.0; 1.0; 1.0.

II.—(a.) 3.9557 grms. of the substance were dissolved in absolute alcohol and titrated with half-normal potash in a way exactly corresponding to that used by Benedikt while determining the "acid value" of the "acetylated" hydroxylated fatty acids. 13.35 cc. half-normal potash were used, yielding an "acid value" of 94.66.

(b.) 1.2858 grms. titrated in the same way required 4.4 cc. half-normal potash corresponding to an "acid value" of 95.9.

An acid of the formula  $C_{17}H_{34}(OC_2H_3O)_2.COOH$  would theoretically require 140. If we were to draw conclusions according to Benedikt we should find from the proportion of the saponification value to the acid value 392 : 95.2 or about 4 : 1 that dihydroxystearic acid contains besides the carboxyl group *three* hydroxyl groups, which is of course absurd. This proves clearly that the "acid values" in this case and such like have no quantitative meaning whatever, indicating only that hydrolysis has taken place.

Benedikt's principle requires some modification to be of use in the analysis of fats. The hydroxylated fatty acids on boiling with acetic anhydride will certainly become acetylated, but at the same time the acetylated acids will be transformed into their anhydrides. It will, therefore, only be safe to infer the presence of hydroxylated fatty acids in a fat if the acid value of the original fatty acids and the saponification value of the "acetylated" fatty acids—*i.e.*, the anhydrides—show a difference large enough to exclude any error naturally adhering to this method. If the presence of hydroxylated acid be proved, the real "acetyl value" will best be found by actually estimating the amount of acetic acid (resp. "acetyl") which has been taken up by the fatty acids. I propose for this purpose a method closely resembling that of Reichert, namely, to distil over the acetic acid formed by complete saponification and estimate it by titration with decinormal potash. The determination of the acetic acid can be conveniently combined with that of the saponification value; care has only to be taken that sulphuric acid be used for titrating back the excess of alcoholic potash and for acidulating the solution of soap. Before adding the sulphuric acid to set the fatty acids free, it will be best to evaporate the alcohol in order to prevent later on formation of acetic ether. In this way I estimated the "acetyl" split off by complete saponification of the above-mentioned 1.5813 grm. In order to neutralise the filtrate, 76.6 cc.  $\frac{1}{10}$  normal potash were used corresponding to 0.3165 grm. acetyl ( $C_2H_3O$ ), while theory requires for 1.5813 grm.—

This method has the additional advantage of enabling us to prove the acetic acid "in substance."

The unsaturated fatty acids of the Sawarri fat (see above) showed an acid value of 188.5; after having been boiled with acetic anhydride the anhydrides gave a saponification value of 230.4, proving the presence of hydroxylated fatty acids. I determined the amount of acetic acid by distillation and found in the distillate a quantity of it corresponding to 8.4 cc. decinormal potash for 3.364 grms., that is 2.5 cc. for one gramme. If we express, as I propose to do, the acetyl value by the number of milligrammes of caustic potash that will be required to saturate the acetic acid which one gramme of the acetylated fatty acid—*i.e.* of the acetylated anhydride—will split off on being saponified, the acetyl value will be in this case  $0.25 \times 56.1 = 14.03$ .

The action of acetic anhydride on organic acids with the production of anhydrides seems to be a general one. Anschütz (Liebig's Annalen, 226, 12) has already studied the inter-action of acetic anhydride with succinic, camphoric, benzoic, *o*-phthalic, and diphenic acids, and found in each case that the acids were partly transformed into their anhydrides. I found the same holds good of sebacic acid.

In conclusion, I may point out that, by adopting my views, Benedikt will easily get over a difficulty which the explanation of the fact that the "acid values" of hydroxylated fatty acids are found lower than the theory requires, seems to offer him.\* He thinks that a small percentage of inner anhydrides of the formula—

(in consequence of a clerical error the paper gives the formula—

\* Chem. Zeit. 1890, No. 51.

might have been formed, but excludes altogether the possibility of the formation of the normal anhydrides—

My explanation by no means precludes the simultaneous formation of inner anhydrides, but it does not postulate it.

## Obituary.

PROFESSOR THOMAS CARNELLEY, D.Sc., F.C.S.,  
A MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY.

On the 27th of August an unexpected blow was sustained by the scientific world through the sudden death of Dr. Thomas Carnelley. Only in his thirty-eighth year, full of hope and promise, and with bright expectations of a further harvest of the fruits of research and literary work, he himself, the worker and investigator, was quickly removed from the field.

Educated at the Owens College, Manchester, where he became Demonstrator and Assistant Lecturer in Chemistry, he thence proceeded as Professor of Chemistry to Firth College, Sheffield, and later on to University College, Dundee.

On the death of Professor Brazier he was, two years ago, appointed to the Chair of Chemistry at the University of Aberdeen.

His most striking investigations were those which embodied the further development of the periodic system of Newlands and Mendeléeff. Up to the time of his decease his mind was concentrated upon a great work on the chemical and physical constants in which he was tracing out relations and uniformities not previously detected. With a mind singularly apt and powerful in tracing scientific analogies, great things might have been further anticipated of him had he been spared. Carnelley's work and investigations on sanitary chemistry were of great interest, and his last research published in conjunction with Mr. Frew on "The Antiseptic Powers of Isomeric Organic Compounds," was of considerable value, not only viewed from the standpoint of pure, but also equally from that of applied chemistry. Among the more useful of his researches may be enumerated the following: "The Results of Passing the Mixed Vapours of Bisulphide of Carbon and Alcohol through a Red-hot Tube," "The Action of Water and Various Saline Solutions on Copper," "On High Melting Points, with special reference to those of Metallic Salts," "Colorimetric Methods of determining small Quantities of Iron and Copper," "Tolyl Phenyl, a New Hydrocarbon," "The Action of Heat on Mercuric Chloride under Low Pressures," "A New Form of Pyrometer," "Oxidation of Di-tolyl," "Brominated Derivatives of Diphenyl, Tollyl-benzene, and Ditollyl," "Amidodiphenylsulphonic Acid and Azo-dyes from Diphenyl," "The Derivatives of Tollyl-benzene," "The Solubility of Isomeric Organic Compounds, and of Mixtures of Sodium and Potassium Nitrates, and the Relation of Solubility to Fusibility," "The Dehydration of Metallic Hydroxides by Heat, with special reference to the Polymerisation of the Oxides and to the Periodic Law."

Let any chemist or chemical technologist read these researches, which form a selection of those recorded in the Journal of the Chemical Society during the last 12 years, and he must come to the conclusion so aptly expressed by a contemporary, that "Thomas Carnelley was a man whom the scientific world could ill spare."

## Journal and Patent\* Literature.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

#### PATENTS.

*Improved Means for Drying or Desiccating Substances or Materials.* P. Cornish, Leyton. Eng. Pat. 6102, April 9, 1889. 8d.

A is a brickwork furnace in which the cylindrical troughs B are set, slightly inclined; each is provided with a "screw creeper," D, of the usual construction, driven by the pulley e and gearing, revolving alternately in opposite directions. The cylinders are heated in the manner shown.

DESICCATION APPARATUS.

The material to be dried is introduced through the hopper *a*, and is passed through the series of cylinders, falling from one to the other, and is finally discharged at *f*, dried by the heated air of the furnace passing both under and over the drying cylinders as shown.—C. C. H.

\* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d. ....	1d.
Above 8d., and not exceeding 1s. 6d. ....	1d.
" 1s. 6d., " " 2s. 4d. ....	1½d.
" 2s. 4d., " " 3s. 4d. ....	2d.

*Improvements in Apparatus for delivering Measured Quantities of Liquid.* F. E. MacMahon, London. Eng. Pat. 13,208, August 21, 1889. 6d.

This invention is an improvement on Eng. Pat. 12,644 of 1888, in which the liquid to be measured was received into, and delivered from a cylinder, the piston of which was allowed to travel a certain distance, dependent on the quantity of liquid to be delivered. Here the apparatus consists of a measuring cylinder and a piston and cock so connected therewith, that in one position of the plug it allows the measuring vessel to fill and the piston to rise; and in another position it allows the measuring vessel to empty by a spout, and the piston to fall, the travel of the piston being regulated by controlling stops according to the amount to be delivered.—E. S.

*Improvements in Apparatus for Softening, Purifying, and Filtering Water.* J. Wright, London. Eng. Pat. 1946, February 5, 1890. 8d.

As upright rectangular tank of considerable height is divided into three parts by vertical partitions. At the top of the whole is placed a regulating cistern dividing the incoming water into two portions. A portion is admitted into one of the sections above described, in which it is mixed with lime, whilst another portion—the bulk of the water treated—is admitted into the mixing division, into which also the lime water and a solution of caustic soda from a separate tank enters. Passing down the mixing portion, the treated water enters the bottom of the remaining division of the apparatus, through which it ascends. The solid matter is arrested on depositing shelves and the partially clarified water, after passing through a tubular filtering apparatus, is delivered at the top of the tank. The incoming water effects the agitation of the lime water as well as the mixture of the reagents with the unpurified water, by means of agitating chains worked by means of small water-wheels.—C. C. H.

*Apparatus for Condensing, Heating or Cooling Gaseous or Liquid Substances.* J. Klein, Frankenthal, Germany. Eng. Pat. 6136, April 22, 1890. 8d.

This apparatus is adapted both to condense and cool gaseous or liquid substances, the object being to increase as much as possible the area of the cold or heat-producing surface (as the case may be), and also to allow of the inner part of the apparatus being readily cleaned.

The apparatus is arranged within a tank, the side walls of which form the frame supporting the cast-iron plates of which the apparatus is constructed. These plates have projecting edges, and when fitted tightly together, form a series of hollow spaces, and are securely connected with the head wall of the tank by connecting rods. When thus fitted together, the whole is surrounded by the water, for the purpose of more thoroughly effecting the condensation of the steam, or the more perfect absorption of the heat of any hot gases or fluids that may be conveyed to the apparatus.

To secure a higher degree of vacuum in the steam chambers, a fine spray, issuing from a valve placed at the end of the apparatus in one of the terminal chambers, and operated externally, is further employed.—E. S.

*Improvements in Filters.* W. P. Thompson, Liverpool. From J. A. Bowden, Detroit, U.S.A. Eng. Pat. 8568, June 3, 1890. 8d.

THE filter can be constructed either in an upright or a horizontal form. In the upright form it is composed of two compartments, one above the other, partially filled with sand or other filtering medium. Upon the bottom of each compartment is a conical-shaped diaphragm, supported clear of the bottom by a perforated screen. The water to be filtered flows down through the sand, the perforated

screen, and beneath the inclined diaphragm to the lower filter bed, and escapes by an outlet pipe. To clean the beds, the water is admitted from below, in each compartment, and causes the sand to rise with it. The sand in the centre flows down the inclined diaphragm to supply the place of that removed, and thus a complete circulation is established, and the bed thoroughly washed. The drawings attached to the specification show both forms of filter. There are six claims.—E. S.

*Apparatus for Automatically Drawing off Viscous Substances.* L. H. A. W. Sack, Berlin, Germany. Eng. Pat. 9554, June 20, 1890. 6d.

This invention is intended to effect the automatic removal from vessels of viscous substances, as syrups, honey, mustard, thick oil colours, and lubricating substances, whilst at the same time the residuum in the vessel is protected from being covered with dust or a film. On the surface of the viscous fluid in the vessel is a plate which bears down upon it under the action of a spiral spring enclosed in a telescopic tube, the upper end of the tube and spring pressing firmly against the cover, which is kept in position by any suitable means. The fluid is drawn off through a plug at the bottom of the vessel.

There are four claims.—E. S.

*An Improved Method and Apparatus for Drying Aqueous Matters.* R. Haddan, London. From E. Passburg, Breslau, Germany. Eng. Pat. 9941, June 26, 1890. 6d.

This invention is an improvement on Eng. Pat. 6326 of 1884, and consists in drying aqueous materials *in vacuo* by means of heat reservoirs in juxtaposition with the matters to be dried, by which means the heat may be transferred to the reservoirs whilst the matters are in juxtaposition therewith, and the temperature of the reservoirs can be maintained for an indefinite time before they are allowed to cool down under the influence of conduction and radiation. An air-tight chamber, connected by a pipe with a condenser and air-pump, has inside it steam compartments formed of metal frames with sheets welded to them on either side. Each side is perforated, and the two holes are connected respectively with the inlet and outlet steam pipes. The apparatus is fed through a door, and metallic trays carrying the substance to be dried are placed on the steam chambers, outside which a vacuum is established. The door is then closed, and the air-pump is worked to remove the vapour from the apparatus; as soon as the material begins to dry steam is shut off to avoid overheating. A gauge and thermometer are attached.—E. S.

## II.—FUEL, GAS, AND LIGHT.

*The Loomis Process of making Gas for Fuel.* R. N. Oakman, jun. The Engineer, August 8, 1890, 107.

By this process three kinds of gas, viz., producer-, water- and carburetted water-gas may be produced for lighting purposes. The paper deals with the two former. The fuel used is a bituminous coal, the slack working the best. The producer-gas passes from the generator through a 20-ft. multitubular boiler, wherein its heat is utilised in producing steam for the water-gas. The alternating operations are each carried on for the same length of time—from 4 to 6 minutes. This is not always the case, however, as the generator is sometimes worked on producer-gas alone, in which case steam is admitted at various points during this operation. For the maximum production of water-gas from a ton of coal more than half a ton is consumed in making producer-gas. The water-gas made by this process is said to possess a strong

odour, due to the presence of about 3 per cent. of olefiant gas, which, however, is omitted from the following two analyses:—

	Water-Gas.	Producer-Gas.
	Per Cent.	Per Cent.
Carbonic acid.....	4.5	7.4
Carbonic oxide.....	36.6	22.5
Hydrogen .....	57.4	13.2
Nitrogen .....	1.5	56.9

The author recommends the production and application of the two gases jointly. The economy is pointed out, but Lowthian Bell states that the use of gaseous fuel represents 30 per cent. loss, and it is only because with gas fuel regeneration is possible that it becomes economical. Solid fuel under proper conditions is the most economical of all.—A. W.

*Testing the Relative Value of Different Coals.* W. Kent.  
Eng. and Min. J. 50, 76—77.

THIS paper contains a description, with full results, of some practical boiler tests of some samples of coal. The author points out the mistake in supposing that the results obtained by testing coals in a boiler under the same conditions represent the relative values of the same coals if they are to be used for a different kind of boiler or for other purposes. Moreover, the figures obtained in tests with the same boiler under the same conditions and with the same fireman, &c. are likely to lead to erroneous conclusions unless they are corrected by the "efficiency of the boiler" as shown during those tests. The first tests of two samples of coal, A and C, gave the water evaporated at 100° C. per pound of coal as 9.311 and 9.302 lb., respectively—a ratio of 100:99.9. The evaporation per pound of combustible, however, was 10.167 and 10.311 lb., or a ratio of 98.60:100. Evidently the conditions, although identical in each case, were more favourable to sample C than A. Consequently if the conditions were such that the efficiency of A was equal to that of C, then the corrected value of C would be to that of A as only 98.5:100 obtained as follows—

$$\therefore 100:98.6::99.9:98.50.$$

A second set of tests was made with a view to obtain increased efficiency by reducing the grate surface to such an extent that the ratio of heating to grate surface was raised from 39.8 to 46.9:1. The actual evaporation in these tests was for A, 9.419 lb., and for C, 9.495 lb., or an apparent relative value of 100:100.81, thus in this instance showing coal C to be superior to coal A, and reversing the result of the first test. The efficiency of the boiler was increased in each case to 10.214 and 10.466 respectively, or a ratio of 97.59:100. Making the correction therefore as before—

$$\therefore 100:97.59::100.81:98.36$$

the relative value of C to A becomes 98.36:100, which agrees well with the corrected figure in the first tests, 98.50.

The author does not recommend this correction as always giving the practical fuel value of a coal, because in many cases increased efficiency could only be obtained at the expense of the capacity of the boiler. He suggests, however, the following rule:—"If in a comparative test of two coals of approximately similar chemical constitution, the apparent relative fuel value as shown by the boiler test differs less than the difference of boiler efficiency in the two tests, then the apparent relative values should be corrected for the difference in boiler efficiency." He is not aware of other experimenters having made use of these corrections, but believes that within the above limits they should be applied in tests made for commercial purposes.—A. W.

*On the Manufacture and Utility of Naphtha Candles.*  
Dingl. Polyt. J. 276, 563—565.

THE so-called naphtha candles were recently shown at an exhibition in St. Petersburg, and although at one time great hopes were entertained of them, it was found that they were not suitable for use.

They consist chiefly of a mixture of ammonia-soap, stearic acid, and mineral oil, this mixture becoming a solid mass, which can be moulded into candles. Such candles, however, smell unpleasantly, as the mineral oil gradually evaporates away. The candles exhibited were made from a mixture composed of 65 per cent. of stearic acid, 30 per cent. of mineral oil, 5 per cent. of water, and about 0.8 per cent. of ammonia. An analysis, made about a month after the candles were manufactured, showed from 10—12 per cent. of mineral oil, 82—85 per cent. of stearic acid, 4.5—5 per cent. of water and 0.6—0.75 per cent. of ammonia. To diminish the evaporation of the mineral oil the candles were coated with various kinds of varnishes, but this, besides being an expensive, was not a satisfactory device. The appearance of the candles was also bad, as they were yellow coloured with white spots. They burned with an unsteady sooty flame and satisfactory photometric observations could not be obtained.—W. M.

PATENTS.

*Improvements in the Manufacture of Gas for Illuminating and other Purposes.* M. H. Strong, Brooklyn, U.S.A.  
Eng. Pat. 2249, June 9, 1877. (Second Edition.) 8d.

A CENTRAL narrow vertical chamber provided with a hopper and feeding apparatus at the top, and with a fire grate and closed ash pit at the bottom, communicates over a baffle-wall with a wide chamber filled with loose brickwork, the lowest part of which is connected with the chimney. A shallow chamber likewise provided with a hopper may optionally be placed on the other side of the central chamber and connected with it. The whole mass is surrounded with non-conducting material and enclosed in a metal casing. The central chamber is heated to a sufficient temperature by an internal fire which is supplied with air by a jet exhauster in the chimney and by a properly regulated air passage in the upper part of the chambers; the air supply is then cut off and the chimney closed by a valve; steam is then admitted into the chimney and becomes superheated in the regenerative chamber. Finely ground coal or liquid hydrocarbon is then introduced in a fine shower into the central chamber, and is volatilised and acted upon by the steam, the resulting gases are further "carburised" by passing through the bed of ignited fuel on the grate, and are drawn off by a pipe opening into the ashpit. The gases may be enriched in illuminating constituents by passing them up again through bituminous coal supplied into the third chamber before withdrawal.—S. B. A. A.

*A New and Improved Carburetted Apparatus for Enriching or Generating Illuminating Gas from Volatile Liquid Hydrocarbons.* H. Howell and L. Smith, London.  
Eng. Pat. 14,686, September 18, 1889. 8d.

THE apparatus is intended for automatically impregnating coal gas or air with hydrocarbon vapour so that the mixture may burn without smoke or smell and without depositing the enriching vapours under normal variations of temperature. It consists of a vertical cylinder divided by a horizontal partition into two compartments, the upper and smaller forming a reservoir for the hydrocarbon and the lower constituting the enriching chamber; a central vent pipe passes through the partition and reaches almost to the top and bottom of the apparatus, and a syphon having its mouth opening near the bottom of the upper compartment has its longer limb either turned up to form a trap or projecting into a small shallow dish immediately under the partition. The enriching chamber contains a series of alternately convex and concave perforated partitions covered with some absorbent fabric except for portions of their surface at the circumference and centre respectively. A shallow

annular pan is fixed near the bottom, the intervening space being occupied by incomplete cylindrical partitions covered with the absorbent fabric. When the hydrocarbon is charged into the reservoir it is conveyed by the syphon into the shallow dish which overflows and saturates the partitions, the drainage from which accumulates in the lower pan which finally overflows, forming a well on the floor of the chamber (the "vent well") which soon seals the vent pipe. The syphon then ceases to act and the reservoir may be filled. Gas or air is admitted above the vent well, passes around the cylindrical partitions, through the central space, round and between the convex and concave partitions, and is drawn off from the upper end of the enriching chamber. As soon as the liquid in the vent well has evaporated sufficiently to unseal the bottom of the vent pipe the syphon again acts and the partitions are drenched with the liquid from the reservoir. A section and sectional plan of the apparatus are shown in the specification.—S. B. A. A.

*Improvements in Internal Combustion Regenerative Thermomotors some of which said Improvements are Applicable to Gas and Hot Air Engines.* J. Hargreaves, Widnes. Eng. Pat. 14,789, September 19, 1889. 8d.

The improvements consist in the first place in the use of two slide valves to regulate the entrance of air into the air pump, its passage into the cooler end of the regenerator, and the exit of the spent gases from the working cylinder after passing through the regenerator, the slide valves being actuated either by two eccentrics or by one eccentric with rocking levers operating at different angles. Secondly it is claimed that the seats of slide valves may be kept true so as not to require frequent re-surfacing, by coupling the slide stems directly to the eccentric straps or levers without pivoting, the slides acquiring in this way an oscillating lateral motion which causes them to wear more uniformly. Lastly, to prevent the accumulation of tarry matter in the working cylinder of thermo-motors when liquid fuel is used, a groove is formed around the working piston at the point which comes opposite the scraper when the piston is at the inner portion of its stroke and the scraper is made with diagonal passages along its face so as to allow any accumulated matter to pass through. The details are fully illustrated in the specification. (Compare this Journal, 1888, 30.)

*Improvements in the Manufacture of Illuminating Gas.* S. Pitt, Sutton. From E. J. Jerzmanowski, New York, U.S.A. Eng. Pat. 9733, June 23, 1890. 6d.

The difficulty generally experienced in the utilisation of low-grade illuminating oils such as crude oil, for enriching gas by the ordinary process of conducting the gas and the illuminant together through heated "fixing retorts," is that the illuminant comes in contact with surfaces continually cooled by the incoming gas and is therefore less thoroughly vaporised and more likely to deposit. In the present invention the oil is conveyed by a pipe which enters the retort from the discharging end and passes along two-thirds of the length of the retort before allowing the oil to escape into the interior. The heated and vaporised oil then turns back upon its course together with the gas, and passes into the delivery pipes. The connections are such that the oil may be heated before entering the retort pipe by passing through pipes in the brickwork around the retorts or through suitable superheaters. An arrangement of steam pipes is shown for chilling the oil supply pipes in cases of over-heating and for keeping the pipes clear.—S. B. A. A.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Apparatus for Fractional Distillation of Crude Naphtha and Naphtha Residues.* Schuchow and Intschik. Dingl. Polyt. J. 276, 465—466.

The apparatus consists of a boiler A, heated from below, and of a vertical series of pans above, the current of vapour and gases rising from the boiler A, through the column of pans in a zig-zag manner, meeting all along its route a flow of liquid crude naphtha entering the apparatus from above through the pipe *a*. This liquid, being previously used in a condenser as a cooling material, is already warmed. Entering through the pipe *i* it falls on the uppermost pan, then by the pipe *d'* to the pan next below, &c. It naturally meets

DISTILLATION OF CRUDE NAPHTHA.
